This behavior of water is the reason lakes freeze from the top down rather than from the bottom up. As water on the surface is cooled from, say, \( 10^\circ C \) toward the freezing point, it becomes denser (“heavier”) than lower water and sinks to the bottom. Below \( 4^\circ C \), however, further cooling makes the water then on the surface less dense (“lighter”) than the lower water, so it stays on the surface until it freezes. Thus the surface freezes while the lower water is still liquid. If lakes froze from the bottom up, the ice so formed would tend not to melt completely during the summer, because it would be insulated by the water above. After a few years, many bodies of open water in the temperate zones of Earth would be frozen solid all year round—and aquatic life could not exist.

\(^b\) This alloy was designed to have a low coefficient of expansion. The word is a shortened form of “invariable.”

---

**Checkpoint 2**

The figure here shows four rectangular metal plates, with sides of \( L, 2L, \) or \( 3L \). They are all made of the same material, and their temperature is to be increased by the same amount. Rank the plates according to the expected increase in (a) their vertical heights and (b) their areas, greatest first.

![Diagram of plates](image)
Sample Problem 18.02  Thermal expansion of a volume

On a hot day in Las Vegas, an oil trucker loaded 37 000 L of diesel fuel. He encountered cold weather on the way to Payson, Utah, where the temperature was 23.0 K lower than in Las Vegas, and where he delivered his entire load. How many liters did he deliver? The coefficient of volume expansion for diesel fuel is 9.50 \times 10^{-4}/\degree C, and the coefficient of linear expansion for his steel truck tank is 11 \times 10^{-6}/\degree C.

**Calculations:** We find
\[\Delta V = (37 \times 10^3 \text{ L})(9.50 \times 10^{-4}/\degree C)(-23.0 \text{ K}) = -808 \text{ L}.\]
Thus, the amount delivered was
\[V_{\text{del}} = V + \Delta V = 37000 \text{ L} - 808 \text{ L} = 36192 \text{ L}.\]

(Answer)

Note that the thermal expansion of the steel tank has nothing to do with the problem. Question: Who paid for the “missing” diesel fuel?

**KEY IDEA**

The volume of the diesel fuel depends directly on the temperature. Thus, because the temperature decreased, the volume of the fuel did also, as given by Eq. 18-10 (\[\Delta V = V\beta \Delta T\]).

---

18-4 ABSORPTION OF HEAT

**Learning Objectives**

After reading this module, you should be able to . . .

18.11 Identify that thermal energy is associated with the random motions of the microscopic bodies in an object.

18.12 Identify that heat \(Q\) is the amount of transferred energy (either to or from an object’s thermal energy) due to a temperature difference between the object and its environment.

18.13 Convert energy units between various measurement systems.

18.14 Convert between mechanical or electrical energy and thermal energy.

18.15 For a temperature change \(\Delta T\) of a substance, relate the change to the heat transfer \(Q\) and the substance’s heat capacity \(C\).

18.16 For a temperature change \(\Delta T\) of a substance, relate the change to the heat transfer \(Q\) and the substance’s specific heat \(c\) and mass \(m\).

18.17 Identify the three phases of matter.

18.18 For a phase change of a substance, relate the heat transfer \(Q\), the heat of transformation \(L\), and the amount of mass \(m\) transformed.

18.19 Identify that if a heat transfer \(Q\) takes a substance across a phase-change temperature, the transfer must be calculated in steps: (a) a temperature change to reach the phase-change temperature, (b) the phase change, and then (c) any temperature change that moves the substance away from the phase-change temperature.

**Key Ideas**

- Heat \(Q\) is energy that is transferred between a system and its environment because of a temperature difference between them. It can be measured in joules (J), calories (cal), kilocalories (Cal or kcal), or British thermal units (Btu), with
  \[1 \text{ cal} = 3.968 \times 10^{-3} \text{ Btu} = 4.1868 \text{ J}.
  \]
- If heat \(Q\) is absorbed by an object, the object’s temperature change \(T_f - T_i\) is related to \(Q\) by
  \[Q = C(T_f - T_i),\]
  in which \(C\) is the heat capacity of the object. If the object has mass \(m\), then
  \[Q = cm(T_f - T_i),\]
  where \(c\) is the specific heat of the material making up the object.

- The molar specific heat of a material is the heat capacity per mole, which means per 6.02 \times 10^{23} elementary units of the material.

- Heat absorbed by a material may change the material’s physical state—for example, from solid to liquid or from liquid to gas. The amount of energy required per unit mass to change the state (but not the temperature) of a particular material is its heat of transformation \(L\). Thus,
  \[Q = Lm.\]

- The heat of vaporization \(L_v\) is the amount of energy per unit mass that must be added to vaporize a liquid or that must be removed to condense a gas.

- The heat of fusion \(L_f\) is the amount of energy per unit mass that must be added to melt a solid or that must be removed to freeze a liquid.
Temperature and Heat

If you take a can of cola from the refrigerator and leave it on the kitchen table, its temperature will rise—rapidly at first but then more slowly—until the temperature of the cola equals that of the room (the two are then in thermal equilibrium). In the same way, the temperature of a cup of hot coffee, left sitting on the table, will fall until it also reaches room temperature.

In generalizing this situation, we describe the cola or the coffee as a *system* (with temperature $T_S$) and the relevant parts of the kitchen as the *environment* (with temperature $T_E$) of that system. Our observation is that if $T_S$ is not equal to $T_E$, then $T_S$ will change ($T_E$ can also change some) until the two temperatures are equal and thus thermal equilibrium is reached.

Such a change in temperature is due to a change in the thermal energy of the system because of a transfer of energy between the system and the system’s environment. (Recall that *thermal energy* is an internal energy that consists of the kinetic and potential energies associated with the random motions of the atoms, molecules, and other microscopic bodies within an object.) The transferred energy is called *heat* and is symbolized $Q$. Heat is *positive* when energy is transferred to a system’s thermal energy from its environment (we say that heat is absorbed by the system). Heat is *negative* when energy is transferred from a system’s thermal energy to its environment (we say that heat is released or lost by the system).

This transfer of energy is shown in Fig. 18-12. In the situation of Fig. 18-12a, in which $T_S > T_E$, energy is transferred from the system to the environment, so $Q$ is negative. In Fig. 18-12b, in which $T_S = T_E$, there is no such transfer, $Q$ is zero, and heat is neither released nor absorbed. In Fig. 18-12c, in which $T_S < T_E$, the transfer is to the system from the environment; so $Q$ is positive.

![Figure 18-12](image-url)

*Figure 18-12* If the temperature of a system exceeds that of its environment as in (a), heat $Q$ is lost by the system to the environment until thermal equilibrium (b) is established. (c) If the temperature of the system is below that of the environment, heat is absorbed by the system until thermal equilibrium is established.
We are led then to this definition of heat:

**Heat is the energy transferred between a system and its environment because of a temperature difference that exists between them.**

**Language.** Recall that energy can also be transferred between a system and its environment as work $W$ via a force acting on a system. Heat and work, unlike temperature, pressure, and volume, are not intrinsic properties of a system. They have meaning only as they describe the transfer of energy into or out of a system. Similarly, the phrase “a $600 transfer” has meaning if it describes the transfer to or from an account, not what is in the account, because the account holds money, not a transfer.

**Units.** Before scientists realized that heat is transferred energy, heat was measured in terms of its ability to raise the temperature of water. Thus, the calorie (cal) was defined as the amount of heat that would raise the temperature of 1 g of water from 14.5°C to 15.5°C. In the British system, the corresponding unit of heat was the **British thermal unit** (Btu), defined as the amount of heat that would raise the temperature of 1 lb of water from 63°F to 64°F.

In 1948, the scientific community decided that since heat (like work) is transferred energy, the SI unit for heat should be the one we use for energy—namely, the **joule**. The calorie is now defined to be 4.1868 J (exactly), with no reference to the heating of water. (The “calorie” used in nutrition, sometimes called the Calorie (Cal), is really a kilocalorie.) The relations among the various heat units are

$$1 \text{ cal} = 3.968 \times 10^{-3} \text{ Btu} = 4.1868 \text{ J}.$$  
(18-12)

### The Absorption of Heat by Solids and Liquids

**Heat Capacity**

The heat capacity $C$ of an object is the proportionality constant between the heat $Q$ that the object absorbs or loses and the resulting temperature change $\Delta T$ of the object; that is,

$$Q = C \Delta T = C(T_f - T_i),$$  
(18-13)

in which $T_i$ and $T_f$ are the initial and final temperatures of the object. Heat capacity $C$ has the unit of energy per degree or energy per kelvin. The heat capacity $C$ of, say, a marble slab used in a bun warmer might be 179 cal/C°, which we can also write as 179 cal/K or as 749 J/K.

The word “capacity” in this context is really misleading in that it suggests analogy with the capacity of a bucket to hold water. *That analogy is false,* and you should not think of the object as “containing” heat or being limited in its ability to absorb heat. Heat transfer can proceed without limit as long as the necessary temperature difference is maintained. The object may, of course, melt or vaporize during the process.

**Specific Heat**

Two objects made of the same material—say, marble—will have heat capacities proportional to their masses. It is therefore convenient to define a “heat capacity per unit mass” or **specific heat** $c$ that refers not to an object but to a unit mass of the material of which the object is made. Equation 18-13 then becomes

$$Q = cm \Delta T = cm(T_f - T_i).$$  
(18-14)

Through experiment we would find that although the heat capacity of a particular marble slab might be 179 cal/C° (or 749 J/K), the specific heat of marble itself (in that slab or in any other marble object) is 0.21 cal/g · C° (or 880 J/kg · K).
From the way the calorie and the British thermal unit were initially defined, the specific heat of water is

\[ c = 1 \text{ cal/g} \cdot \text{C}^\circ = 1 \text{ Btu/lb} \cdot \text{F}^\circ = 4186.8 \text{ J/kg} \cdot \text{K}. \]  

(18-15)

Table 18-3 shows the specific heats of some substances at room temperature. Note that the value for water is relatively high. The specific heat of any substance actually depends somewhat on temperature, but the values in Table 18-3 apply reasonably well in a range of temperatures near room temperature.

**Checkpoint 3**

A certain amount of heat \( Q \) will warm 1 g of material \( A \) by 3 C\(^\circ\) and 1 g of material \( B \) by 4 C\(^\circ\). Which material has the greater specific heat?

### Molar Specific Heat

In many instances the most convenient unit for specifying the amount of a substance is the mole (mol), where

\[ 1 \text{ mol} = 6.02 \times 10^{23} \text{ elementary units} \]

of *any* substance. Thus 1 mol of aluminum means \( 6.02 \times 10^{23} \) atoms (the atom is the elementary unit), and 1 mol of aluminum oxide means \( 6.02 \times 10^{23} \) molecules (the molecule is the elementary unit of the compound).

When quantities are expressed in moles, specific heats must also involve moles (rather than a mass unit); they are then called **molar specific heats**. Table 18-3 shows the values for some elemental solids (each consisting of a single element) at room temperature.

### An Important Point

In determining and then using the specific heat of any substance, we need to know the conditions under which energy is transferred as heat. For solids and liquids, we usually assume that the sample is under constant pressure (usually atmospheric) during the transfer. It is also conceivable that the sample is held at constant volume while the heat is absorbed. This means that thermal expansion of the sample is prevented by applying external pressure. For solids and liquids, this is very hard to arrange experimentally, but the effect can be calculated, and it turns out that the specific heats under constant pressure and constant volume for any solid or liquid differ usually by no more than a few percent. Gases, as you will see, have quite different values for their specific heats under constant-pressure conditions and under constant-volume conditions.

### Heats of Transformation

When energy is absorbed as heat by a solid or liquid, the temperature of the sample does not necessarily rise. Instead, the sample may change from one **phase**, or **state**, to another. Matter can exist in three common states: In the **solid state**, the molecules of a sample are locked into a fairly rigid structure by their mutual attraction. In the **liquid state**, the molecules have more energy and move about more. They may form brief clusters, but the sample does not have a rigid structure and can flow or settle into a container. In the **gas**, or **vapor**, state, the molecules have even more energy, are free of one another, and can fill up the full volume of a container.

**Melting.** To **melt** a solid means to change it from the solid state to the liquid state. The process requires energy because the molecules of the solid must be freed from their rigid structure. Melting an ice cube to form liquid water is a common example. To **freeze** a liquid to form a solid is the reverse of melting and requires that energy be removed from the liquid, so that the molecules can settle into a rigid structure.

</table>

**Vaporizing.** To **vaporize** a liquid means to change it from the liquid state to the vapor (gas) state. This process, like melting, requires energy because the molecules must be freed from their clusters. Boiling liquid water to transfer it to water vapor (or steam—a gas of individual water molecules) is a common example. **Condensing** a gas to form a liquid is the reverse of vaporizing; it requires that energy be removed from the gas, so that the molecules can cluster instead of flying away from one another.

The amount of energy per unit mass that must be transferred as heat when a sample completely undergoes a phase change is called the **heat of transformation** $L$. Thus, when a sample of mass $m$ completely undergoes a phase change, the total energy transferred is

$$Q = Lm.$$  \hspace{1cm} (18-16)

When the phase change is from liquid to gas (then the sample must absorb heat) or from gas to liquid (then the sample must release heat), the heat of transformation is called the **heat of vaporization** $L_V$. For water at its normal boiling or condensation temperature,

$$L_V = 539 \text{ cal/g} = 40.7 \text{ kJ/mol} = 2256 \text{ kJ/kg}. \hspace{1cm} (18-17)$$

When the phase change is from solid to liquid (then the sample must absorb heat) or from liquid to solid (then the sample must release heat), the heat of transformation is called the **heat of fusion** $L_F$. For water at its normal freezing or melting temperature,

$$L_F = 79.5 \text{ cal/g} = 6.01 \text{ kJ/mol} = 333 \text{ kJ/kg}. \hspace{1cm} (18-18)$$

Table 18-4 shows the heats of transformation for some substances.

---

**Sample Problem 18.03**  **Hot slug in water, coming to equilibrium**

A copper slug whose mass $m_c$ is 75 g is heated in a laboratory oven to a temperature $T$ of 312°C. The slug is then dropped into a glass beaker containing a mass $m_w = 220$ g of water. The heat capacity $C_b$ of the beaker is 45 cal/K. The initial temperature $T_i$ of the water and the beaker is 12°C. Assuming that the slug, beaker, and water are an isolated system and the water does not vaporize, find the final temperature $T_f$ of the system at thermal equilibrium.

**KEY IDEAS**

(1) Because the system is isolated, the system’s total energy cannot change and only internal transfers of thermal energy can occur. (2) Because nothing in the system undergoes a phase change, the thermal energy transfers can only change the temperatures.

**Calculations:** To relate the transfers to the temperature changes, we can use Eqs. 18-13 and 18-14 to write

- for the water: $Q_w = c_w m_w (T_f - T_i)$;  \hspace{1cm} (18-19)
- for the beaker: $Q_b = C_b (T_f - T_i)$;  \hspace{1cm} (18-20)
- for the copper: $Q_c = c_m m_c (T_f - T_i)$.  \hspace{1cm} (18-21)

Because the total energy of the system cannot change, the sum of these three energy transfers is zero:

$$Q_w + Q_b + Q_c = 0.$$  \hspace{1cm} (18-22)
Substituting Eqs. 18-19 through 18-21 into Eq. 18-22 yields
\[ c_w m_w (T_f - T) + C_b (T_f - T) + c_m (T_f - T) = 0. \] (18-23)

Temperatures are contained in Eq. 18-23 only as differences. Thus, because the differences on the Celsius and Kelvin scales are identical, we can use either of those scales in this equation. Solving it for \( T_f \), we obtain
\[ T_f = \frac{c_m T + C_b T + c_w m_w T}{c_m m_w + C_b + c_w m_c}. \]

Using Celsius temperatures and taking values for \( c_c \) and \( c_w \) from Table 18-3, we find the numerator to be
\[ (0.0923 \text{ cal/g} \cdot \text{K})(75 \text{ g})(312\text{°C}) + (45 \text{ cal/K})(12\text{°C}) \]
\[ + (1.00 \text{ cal/g} \cdot \text{K})(220 \text{ g})(12\text{°C}) = 5339.8 \text{ cal}, \]
and the denominator to be
\[ (1.00 \text{ cal/g} \cdot \text{K})(220 \text{ g}) + 45 \text{ cal/K} \]
\[ + (0.0923 \text{ cal/g} \cdot \text{K})(75 \text{ g}) = 271.9 \text{ cal/C}. \]

We then have
\[ T_f = \frac{5339.8 \text{ cal}}{271.9 \text{ cal/C}} = 19.6\text{°C} \approx 20\text{°C}. \] (Answer)

From the given data you can show that
\[ Q_w \approx 1670 \text{ cal}, \quad Q_b \approx 342 \text{ cal}, \quad Q_c \approx -2020 \text{ cal}. \]

Apart from rounding errors, the algebraic sum of these three heat transfers is indeed zero, as required by the conservation of energy (Eq. 18-22).

**Sample Problem 18.04 Heat to change temperature and state**

(a) How much heat must be absorbed by ice of mass \( m = 720 \text{ g} \) at \(-10\text{°C}\) to take it to the liquid state at \(15\text{°C}\)?

**KEY IDEAS**

The heating process is accomplished in three steps: (1) The ice cannot melt at a temperature below the freezing point—so initially, any energy transferred to the ice as heat can only increase the temperature of the ice, until \(0\text{°C}\) is reached. (2) The temperature then cannot increase until all the ice melts—so any energy transferred to the ice as heat can only change ice to liquid water, until all the ice melts. (3) Now the energy transferred to the liquid water as heat can only increase the temperature of the liquid water.

*Warming the ice:* The heat \( Q_1 \) needed to take the ice from the initial \( T_i = -10\text{°C} \) to the final \( T_f = 0\text{°C} \) (so that the ice can then melt) is given by Eq. 18-14 \((Q = cm \Delta T)\). Using the specific heat of ice \( c_i \) in Table 18-3 gives us
\[ Q_1 = c_i m_i (T_f - T_i) \]
\[ = (2220 \text{ J/kg} \cdot \text{K})(0.720 \text{ kg})(0\text{°C} - (-10\text{°C})) \]
\[ = 15984 \text{ J} = 15.98 \text{ kJ}. \]

*Melting the ice:* The heat \( Q_2 \) needed to melt all the ice is given by Eq. 18-16 \((Q = Lm)\). Here \( L \) is the heat of fusion \( L_F \), with the value given in Eq. 18-18 and Table 18-4. We find
\[ Q_2 = L_F m = (333 \text{ kJ/kg})(0.720 \text{ kg}) \approx 239.8 \text{ kJ}. \]

*Warming the liquid:* The heat \( Q_3 \) needed to increase the temperature of the water from the initial value \( T_i = 0\text{°C} \) to the final value \( T_f = 15\text{°C} \) is given by Eq. 18-14 (with the specific heat of liquid water \( c_{\text{liq}} \)):
\[ Q_3 = c_{\text{liq}} m_i (T_f - T_i) \]
\[ = (4186.8 \text{ J/kg} \cdot \text{K})(0.720 \text{ kg})(15\text{°C} - 0\text{°C}) \]
\[ = 45217 \text{ J} = 45.22 \text{ kJ}. \]

**Total:** The total required heat \( Q_{\text{tot}} \) is the sum of the amounts required in the three steps:
\[ Q_{\text{tot}} = Q_1 + Q_2 + Q_3 \]
\[ = 15.98 \text{ kJ} + 239.8 \text{ kJ} + 45.22 \text{ kJ} \]
\[ = 300 \text{ kJ}. \] (Answer)

Note that most of the energy goes into melting the ice rather than raising the temperature.

(b) If we supply the ice with a total energy of only 210 kJ (as heat), what are the final state and temperature of the water?

**KEY IDEA**

From step 1, we know that 15.98 kJ is needed to raise the temperature of the ice to the melting point. The remaining heat \( Q_{\text{rem}} \) is then 210 kJ – 15.98 kJ, or about 194 kJ. From step 2, we can see that this amount of heat is insufficient to melt all the ice. Because the melting of the ice is incomplete, we must end up with a mixture of ice and liquid; the temperature of the mixture must be the freezing point, 0°C.

**Calculations:** We can find the mass \( m \) of ice that is melted by the available energy \( Q_{\text{rem}} \) by using Eq. 18-16 with \( L_F \):
\[ m = \frac{Q_{\text{rem}}}{L_F} = \frac{194 \text{ kJ}}{333 \text{ kJ/kg}} = 0.583 \text{ kg} = 580 \text{ g}. \]

Thus, the mass of the ice that remains is 720 g – 580 g, or 140 g, and we have
\[ 580 \text{ g water and 140 g ice, at 0°C}. \] (Answer)

18-5 THE FIRST LAW OF THERMODYNAMICS

Learning Objectives

After reading this module, you should be able to . . .

18.20 If an enclosed gas expands or contracts, calculate the work \( W \) done by the gas by integrating the gas pressure with respect to the volume of the enclosure.

18.21 Identify the algebraic sign of work \( W \) associated with expansion and contraction of a gas.

18.22 Given a \( p-V \) graph of pressure versus volume for a process, identify the starting point (the initial state) and the final point (the final state) and calculate the work by using graphical integration.

18.23 On a \( p-V \) graph of pressure versus volume for a gas, identify the algebraic sign of the work associated with a right-going process and a left-going process.

18.24 Apply the first law of thermodynamics to relate the change in the internal energy \( \Delta E_{\text{int}} \) of a gas, the energy \( Q \) transferred as heat to or from the gas, and the work \( W \) done on or by the gas.

Key Ideas

- A gas may exchange energy with its surroundings through work. The amount of work \( W \) done by a gas as it expands or contracts from an initial volume \( V_i \) to a final volume \( V_f \) is given by

\[
W = \int dW = \int_{V_i}^{V_f} p \, dV.
\]

The integration is necessary because the pressure \( p \) may vary during the volume change.

- The principle of conservation of energy for a thermodynamic process is expressed in the first law of thermodynamics, which may assume either of the forms

\[
\Delta E_{\text{int}} = E_{\text{int},f} - E_{\text{int},i} = Q - W \quad \text{(first law)}
\]

or

\[
dE_{\text{int}} = dQ - dW \quad \text{(first law)}.
\]

\( E_{\text{int}} \) represents the internal energy of the material, which depends only on the material’s state (temperature, pressure, and volume). \( Q \) represents the energy exchanged as heat between the system and its surroundings; \( Q \) is positive if the system absorbs heat and negative if the system loses heat. \( W \) is the work done by the system; \( W \) is positive if the system expands against an external force from the surroundings and negative if the system contracts because of an external force.

- \( Q \) and \( W \) are path dependent; \( \Delta E_{\text{int}} \) is path independent.

- The first law of thermodynamics finds application in several special cases:

  - **Adiabatic processes:** \( Q = 0, \quad \Delta E_{\text{int}} = -W \)
  - **Constant-volume processes:** \( W = 0, \quad \Delta E_{\text{int}} = Q \)
  - **Cyclical processes:** \( \Delta E_{\text{int}} = 0, \quad Q = W \)
  - **Free expansions:** \( Q = W = \Delta E_{\text{int}} = 0 \)

A Closer Look at Heat and Work

Here we look in some detail at how energy can be transferred as heat and work between a system and its environment. Let us take as our system a gas confined to a cylinder with a movable piston, as in Fig. 18-13. The upward force on the piston due to the pressure of the confined gas is equal to the weight of lead shot loaded onto the top of the piston. The walls of the cylinder are made of insulating material that does not allow any transfer of energy as heat. The bottom of the cylinder rests on a reservoir for thermal energy, a *thermal reservoir* (perhaps a hot plate) whose temperature \( T \) you can control by turning a knob.

The system (the gas) starts from an initial state \( i \), described by a pressure \( p_i \), a volume \( V_i \), and a temperature \( T_i \). You want to change the system to a final state \( f \), described by a pressure \( p_f \), a volume \( V_f \), and a temperature \( T_f \). The procedure by which you change the system from its initial state to its final state is called a *thermodynamic process*. During such a process, energy may be trans-
ferred into the system from the thermal reservoir (positive heat) or vice versa (negative heat). Also, work can be done by the system to raise the loaded piston (positive work) or lower it (negative work). We assume that all such changes occur slowly, with the result that the system is always in (approximate) thermal equilibrium (every part is always in thermal equilibrium).

Suppose that you remove a few lead shot from the piston of Fig. 18-13, allowing the gas to push the piston and remaining shot upward through a differential displacement $d\vec{s}$ with an upward force $\vec{F}$. Since the displacement is tiny, we can assume that $\vec{F}$ is constant during the displacement. Then $\vec{F}$ has a magnitude that is equal to $pA$, where $p$ is the pressure of the gas and $A$ is the face area of the piston.

The differential work $dW$ done by the gas during the displacement is

$$dW = \vec{F} \cdot d\vec{s} = (pA)(ds) = p(A\, ds)$$

in which $dV$ is the differential change in the volume of the gas due to the movement of the piston. When you have removed enough shot to allow the gas to change its volume from $V_i$ to $V_f$, the total work done by the gas is

$$W = \int dW = \int_{V_i}^{V_f} p\, dV.$$  \hspace{1cm} (18-25)

During the volume change, the pressure and temperature may also change. To evaluate Eq. 18-25 directly, we would need to know how pressure varies with volume for the actual process by which the system changes from state $i$ to state $f$.

**One Path.**

There are actually many ways to take the gas from state $i$ to state $f$. One way is shown in Fig. 18-14a, which is a plot of the pressure of the gas versus its volume and which is called a $p$-$V$ diagram. In Fig. 18-14a, the curve indicates that the

![Image](image_url)
CheckPoint 4

The p-V diagram here shows six curved paths (connected by vertical paths) that can be followed by a gas. Which two of the curved paths should be part of a closed cycle (those curved paths plus connecting vertical paths) if the net work done by the gas during the cycle is to be at its maximum positive value?
The First Law of Thermodynamics

You have just seen that when a system changes from a given initial state to a given final state, both the work $W$ and the heat $Q$ depend on the nature of the process. Experimentally, however, we find a surprising thing. The quantity $Q - W$ is the same for all processes. It depends only on the initial and final states and does not depend at all on how the system gets from one to the other. All other combinations of $Q$ and $W$, including $Q$ alone, $W$ alone, $Q + W$, and $Q - 2W$, are path dependent; only the quantity $Q - W$ is not.

The quantity $Q - W$ must represent a change in some intrinsic property of the system. We call this property the internal energy $E_{\text{int}}$ and we write

$$\Delta E_{\text{int}} = E_{\text{int},f} - E_{\text{int},i} = Q - W \quad \text{(first law).} \quad (18-26)$$

Equation 18-26 is the first law of thermodynamics. If the thermodynamic system undergoes only a differential change, we can write the first law as*

$$dE_{\text{int}} = dQ - dW \quad \text{(first law).} \quad (18-27)$$

The internal energy $E_{\text{int}}$ of a system tends to increase if energy is added as heat $Q$ and tends to decrease if energy is lost as work $W$ done by the system.

In Chapter 8, we discussed the principle of energy conservation as it applies to isolated systems—that is, to systems in which no energy enters or leaves the system. The first law of thermodynamics is an extension of that principle to systems that are not isolated. In such cases, energy may be transferred into or out of the system as either work $W$ or heat $Q$. In our statement of the first law of thermodynamics above, we assume that there are no changes in the kinetic energy or the potential energy of the system as a whole; that is, $\Delta K = \Delta U = 0$.

**Rules.** Before this chapter, the term *work* and the symbol $W$ always meant the work done *on* a system. However, starting with Eq. 18-24 and continuing through the next two chapters about thermodynamics, we focus on the work done *by* a system, such as the gas in Fig. 18-13.

The work done *on* a system is always the negative of the work done *by* the system, so if we rewrite Eq. 18-26 in terms of the work $W_{\text{on}}$ done *on* the system, we have $\Delta E_{\text{int}} = Q + W_{\text{on}}$. This tells us the following: The internal energy of a system tends to increase if heat is absorbed by the system or if positive work is done *on* the system. Conversely, the internal energy tends to decrease if heat is lost by the system or if negative work is done *on* the system.

**Checkpoint 5**

The figure here shows four paths on a $p$-$V$ diagram along which a gas can be taken from state $i$ to state $f$. Rank the paths according to (a) the change $\Delta E_{\text{int}}$ in the internal energy of the gas, (b) the work $W$ done by the gas, and (c) the magnitude of the energy transferred as heat $Q$ between the gas and its environment, greatest first.

---

*Here $dQ$ and $dW$, unlike $dE_{\text{int}}$, are not true differentials; that is, there are no such functions as $Q(p, V)$ and $W(p, V)$ that depend only on the state of the system. The quantities $dQ$ and $dW$ are called inexact differentials and are usually represented by the symbols $dQ$ and $dW$. For our purposes, we can treat them simply as infinitesimally small energy transfers.*
Some Special Cases of the First Law of Thermodynamics

Here are four thermodynamic processes as summarized in Table 18-5.

1. **Adiabatic processes.** An adiabatic process is one that occurs so rapidly or occurs in a system that is so well insulated that no transfer of energy as heat occurs between the system and its environment. Putting \( Q = 0 \) in the first law (Eq. 18-26) yields

\[
\Delta E_{\text{int}} = -W \quad \text{(adiabatic process)}.
\]

This tells us that if work is done by the system (that is, if \( W \) is positive), the internal energy of the system decreases by the amount of work. Conversely, if work is done on the system (that is, if \( W \) is negative), the internal energy of the system increases by that amount.

Figure 18-15 shows an idealized adiabatic process. Heat cannot enter or leave the system because of the insulation. Thus, the only way energy can be transferred between the system and its environment is by work. If we remove shot from the piston and allow the gas to expand, the work done by the system (the gas) is positive and the internal energy of the gas decreases. If, instead, we add shot and compress the gas, the work done by the system is negative and the internal energy of the gas increases.

2. **Constant-volume processes.** If the volume of a system (such as a gas) is held constant, that system can do no work. Putting \( W = 0 \) in the first law (Eq. 18-26) yields

\[
\Delta E_{\text{int}} = Q \quad \text{(constant-volume process)}.
\]

Thus, if heat is absorbed by a system (that is, if \( Q \) is positive), the internal energy of the system increases. Conversely, if heat is lost during the process (that is, if \( Q \) is negative), the internal energy of the system must decrease.

3. **Cyclical processes.** There are processes in which, after certain interchanges of heat and work, the system is restored to its initial state. In that case, no intrinsic property of the system—including its internal energy—can possibly change. Putting \( \Delta E_{\text{int}} = 0 \) in the first law (Eq. 18-26) yields

\[
Q = W \quad \text{(cyclical process)}.
\]

Thus, the net work done during the process must exactly equal the net amount of energy transferred as heat; the store of internal energy of the system remains unchanged. Cyclical processes form a closed loop on a \( p-V \) plot, as shown in Fig. 18-14f. We discuss such processes in detail in Chapter 20.

4. **Free expansions.** These are adiabatic processes in which no transfer of heat occurs between the system and its environment and no work is done on or by the system. Thus, \( Q = W = 0 \), and the first law requires that

\[
\Delta E_{\text{int}} = 0 \quad \text{(free expansion)}.
\]

Figure 18-16 shows how such an expansion can be carried out. A gas, which is in thermal equilibrium within itself, is initially confined by a closed stopcock to one half of an insulated double chamber; the other half is evacuated. The stopcock is opened, and the gas expands freely to fill both halves of the chamber. No heat is transferred.

---

### Table 18-5 The First Law of Thermodynamics: Four Special Cases

<table>

<td>( \Delta E_{\text{int}} = -W )</td>
</tr>
<tr>
<td>Constant volume</td>
<td>( W = 0 )</td>
<td>( \Delta E_{\text{int}} = Q )</td>
</tr>
<tr>
<td>Closed cycle</td>
<td>( \Delta E_{\text{int}} = 0 )</td>
<td>( Q = W )</td>
</tr>
<tr>
<td>Free expansion</td>
<td>( Q = W = 0 )</td>
<td>( \Delta E_{\text{int}} = 0 )</td>
</tr>
</tbody>
</table>
transferred to or from the gas because of the insulation. No work is done by the gas because it rushes into a vacuum and thus does not meet any pressure.

A free expansion differs from all other processes we have considered because it cannot be done slowly and in a controlled way. As a result, at any given instant during the sudden expansion, the gas is not in thermal equilibrium and its pressure is not uniform. Thus, although we can plot the initial and final states on a \( p-V \) diagram, we cannot plot the expansion itself.

**Checkpoint 6**

For one complete cycle as shown in the \( p-V \) diagram here, are (a) \( \Delta E_{\text{int}} \) for the gas and (b) the net energy transferred as heat \( Q \) positive, negative, or zero?

---

**Sample Problem 18.05  First law of thermodynamics: work, heat, internal energy change**

Let 1.00 kg of liquid water at 100°C be converted to steam at 100°C by boiling at standard atmospheric pressure (which is 1.00 atm or \( 1.01 \times 10^5 \) Pa) in the arrangement of Fig. 18-17. The volume of that water changes from an initial value of \( 1.00 \times 10^{-3} \) m\(^3\) as a liquid to 1.671 m\(^3\) as steam.

(a) How much work is done by the system during this process?

**KEY IDEAS**

(1) The system must do positive work because the volume increases. (2) We calculate the work \( W \) done by integrating the pressure with respect to the volume (Eq. 18-25).

**Calculation:** Because here the pressure is constant at \( 1.01 \times 10^5 \) Pa, we can take \( p \) outside the integral. Thus,

\[
W = \int_{V_i}^{V_f} p \, dV = p \int_{V_i}^{V_f} dV = p(V_f - V_i) \\
= (1.01 \times 10^5 \text{ Pa})(1.671 \text{ m}^3 - 1.00 \times 10^{-3} \text{ m}^3) \\
= 1.69 \times 10^5 \text{ J} \approx 169 \text{ kJ}. \quad \text{(Answer)}
\]

(b) How much energy is transferred as heat during the process?

**KEY IDEA**

Because the heat causes only a phase change and not a change in temperature, it is given fully by Eq. 18-16 (\( Q = Lm \)).

**Calculation:** Because the change is from liquid to gaseous phase, \( L \) is the heat of vaporization \( L_V \), with the value given in Eq. 18-17 and Table 18-4. We find

\[
Q = L_V m = (2256 \text{ kJ/kg})(1.00 \text{ kg}) \\
= 2256 \text{ kJ} \approx 2260 \text{ kJ}. \quad \text{(Answer)}
\]

(c) What is the change in the system’s internal energy during the process?

---

Additional examples, video, and practice available at *WileyPLUS*
18-6 HEAT TRANSFER MECHANISMS

Learning Objectives

After reading this module, you should be able to . . .

18.31 For thermal conduction through a layer, apply the relationship between the energy-transfer rate \( P_{\text{cond}} \) and the layer’s area \( A \), thermal conductivity \( k \), thickness \( L \), and temperature difference \( \Delta T \) (between its two sides).

18.32 For a composite slab (two or more layers) that has reached the steady state in which temperatures are no longer changing, identify that (by the conservation of energy) the rates of thermal conduction \( P_{\text{cond}} \) through the layers must be equal.

18.33 For thermal conduction through a layer, apply the relationship between thermal resistance \( R \), thickness \( L \), and thermal conductivity \( k \).

18.34 Identify that thermal energy can be transferred by convection, in which a warmer fluid (gas or liquid) tends to rise in a cooler fluid.

18.35 In the emission of thermal radiation by an object, apply the relationship between the energy-transfer rate \( P_{\text{rad}} \) and the object’s surface area \( A \), emissivity \( \varepsilon \), and surface temperature \( T \) (in kelvins).

18.36 In the absorption of thermal radiation by an object, apply the relationship between the energy-transfer rate \( P_{\text{abs}} \) and the object’s surface area \( A \) and emissivity \( \varepsilon \), and the environmental temperature \( T \) (in kelvins).

18.37 Calculate the net energy-transfer rate \( P_{\text{net}} \) of an object emitting radiation to its environment and absorbing radiation from that environment.

Key Ideas

- The rate \( P_{\text{cond}} \) at which energy is conducted through a slab for which one face is maintained at the higher temperature \( T_H \) and the other face is maintained at the lower temperature \( T_C \) is

\[
P_{\text{cond}} = \frac{Q}{t} = kA \frac{T_H - T_C}{L}.
\]

Here each face of the slab has area \( A \), the length of the slab (the distance between the faces) is \( L \), and \( k \) is the thermal conductivity of the material.

- Convection occurs when temperature differences cause an energy transfer by motion within a fluid.

- Radiation is an energy transfer via the emission of electromagnetic energy. The rate \( P_{\text{rad}} \) at which an object emits energy via thermal radiation is

\[
P_{\text{rad}} = \sigma A T^4,
\]

where \( \sigma = 5.6704 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \) is the Stefan–Boltzmann constant, \( \varepsilon \) is the emissivity of the object’s surface, \( A \) is its surface area, and \( T \) is its surface temperature (in kelvins). The rate \( P_{\text{abs}} \) at which an object absorbs energy via thermal radiation from its environment, which is at the uniform temperature \( T_{\text{env}} \) (in kelvins), is

\[
P_{\text{abs}} = \sigma A T_{\text{env}}^4.
\]

Heat Transfer Mechanisms

We have discussed the transfer of energy as heat between a system and its environment, but we have not yet described how that transfer takes place. There are three transfer mechanisms: conduction, convection, and radiation. Let’s next examine these mechanisms in turn.

Conduction

If you leave the end of a metal poker in a fire for enough time, its handle will get hot. Energy is transferred from the fire to the handle by (thermal) conduction along the length of the poker. The vibration amplitudes of the atoms and electrons of the metal at the fire end of the poker become relatively large because of the high temperature of their environment. These increased vibrational amplitudes, and thus the associated energy, are passed along the poker, from atom to atom, during collisions between adjacent atoms. In this way, a region of rising temperature extends itself along the poker to the handle.

Consider a slab of face area \( A \) and thickness \( L \), whose faces are maintained at temperatures \( T_H \) and \( T_C \) by a hot reservoir and a cold reservoir, as in Fig. 18-18. Let \( Q \) be the energy that is transferred as heat through the slab, from its hot face to its cold face, in time \( t \). Experiment shows that the conduction rate \( P_{\text{cond}} \) (the
amount of energy transferred per unit time) is

\[ P_{\text{cond}} = \frac{Q}{t} = kA \frac{T_H - T_C}{L}, \quad (18-32) \]

in which \( k \), called the thermal conductivity, is a constant that depends on the material of which the slab is made. A material that readily transfers energy by conduction is a good thermal conductor and has a high value of \( k \). Table 18-6 gives the thermal conductivities of some common metals, gases, and building materials.

**Thermal Resistance to Conduction (R-Value)**

If you are interested in insulating your house or in keeping cola cans cold on a picnic, you are more concerned with poor heat conductors than with good ones. For this reason, the concept of thermal resistance \( R \) has been introduced into engineering practice. The \( R \)-value of a slab of thickness \( L \) is defined as

\[ R = \frac{L}{k}. \quad (18-33) \]

The lower the thermal conductivity of the material of which a slab is made, the higher the \( R \)-value of the slab; so something that has a high \( R \)-value is a poor thermal conductor and thus a good thermal insulator.

Note that \( R \) is a property attributed to a slab of a specified thickness, not to a material. The commonly used unit for \( R \) (which, in the United States at least, is almost never stated) is the square foot–Fahrenheit degree–hour per British thermal unit (\( \text{ft}^2 \cdot \text{°F} \cdot \text{h}/\text{Btu} \)). (Now you know why the unit is rarely stated.)

**Conduction Through a Composite Slab**

Figure 18-19 shows a composite slab, consisting of two materials having different thicknesses \( L_1 \) and \( L_2 \) and different thermal conductivities \( k_1 \) and \( k_2 \). The temperatures of the outer surfaces of the slab are \( T_H \) and \( T_C \). Each face of the slab has area \( A \). Let us derive an expression for the conduction rate through the slab under the assumption that the transfer is a steady-state process; that is, the temperatures everywhere in the slab and the rate of energy transfer do not change with time.

In the steady state, the conduction rates through the two materials must be equal. This is the same as saying that the energy transferred through one material in a certain time must be equal to that transferred through the other material in the same time. If this were not true, temperatures in the slab would be changing and we would not have a steady-state situation. Letting \( T_X \) be the temperature of the interface between the two materials, we can now use Eq. 18-32 to write

\[ P_{\text{cond}} = \frac{k_2A(T_H - T_X)}{L_2} = \frac{k_1A(T_X - T_C)}{L_1}. \quad (18-34) \]

Solving Eq. 18-34 for \( T_X \) yields, after a little algebra,

\[ T_X = \frac{k_1L_2T_C + k_2L_1T_H}{k_1L_2 + k_2L_1}. \quad (18-35) \]

Substituting this expression for \( T_X \) into either equality of Eq. 18-34 yields

\[ P_{\text{cond}} = \frac{A(T_H - T_C)}{L_1/k_1 + L_2/k_2}. \quad (18-36) \]

We can extend Eq. 18-36 to apply to any number \( n \) of materials making up a slab:

\[ P_{\text{cond}} = \frac{A(T_H - T_C)}{\sum (L/k)}. \quad (18-37) \]

The summation sign in the denominator tells us to add the values of \( L/k \) for all the materials.
CHAPTER 18  TEMPERATURE, HEAT, AND THE FIRST LAW OF THERMODYNAMICS

Figure 18-20  A false-color thermogram reveals the rate at which energy is radiated by a cat. The rate is color-coded, with white and red indicating the greatest radiation rate. The nose is cool.

Checkpoint 7

The figure shows the face and interface temperatures of a composite slab consisting of four materials, of identical thicknesses, through which the heat transfer is steady. Rank the materials according to their thermal conductivities, greatest first.

Convection

When you look at the flame of a candle or a match, you are watching thermal energy being transported upward by convection. Such energy transfer occurs when a fluid, such as air or water, comes in contact with an object whose temperature is higher than that of the fluid. The temperature of the part of the fluid that is in contact with the hot object increases, and (in most cases) that fluid expands and thus becomes less dense. Because this expanded fluid is now lighter than the surrounding cooler fluid, buoyant forces cause it to rise. Some of the surrounding cooler fluid then flows so as to take the place of the rising warmer fluid, and the process can then continue.

Convection is part of many natural processes. Atmospheric convection plays a fundamental role in determining global climate patterns and daily weather variations. Glider pilots and birds alike seek rising thermals (convection currents of warm air) that keep them aloft. Huge energy transfers take place within the oceans by the same process. Finally, energy is transported to the surface of the Sun from the nuclear furnace at its core by enormous cells of convection, in which hot gas rises to the surface along the cell core and cooler gas around the core descends below the surface.

Radiation

The third method by which an object and its environment can exchange energy as heat is via electromagnetic waves (visible light is one kind of electromagnetic wave). Energy transferred in this way is often called thermal radiation to distinguish it from electromagnetic signals (as in, say, television broadcasts) and from nuclear radiation (energy and particles emitted by nuclei). (To “radiate” generally means to emit.) When you stand in front of a big fire, you are warmed by absorbing thermal radiation from the fire; that is, your thermal energy increases as the fire’s thermal energy decreases. No medium is required for heat transfer via radiation—the radiation can travel through vacuum from, say, the Sun to you.

The rate $P_{\text{rad}}$ at which an object emits energy via electromagnetic radiation depends on the object’s surface area $A$ and the temperature $T$ of that area in kelvins and is given by

$$P_{\text{rad}} = \sigma \varepsilon A T^4.$$ (18-38)

Here $\sigma = 5.6704 \times 10^{-8}$ W/m²·K⁴ is called the Stefan–Boltzmann constant after Josef Stefan (who discovered Eq. 18-38 experimentally in 1879) and Ludwig Boltzmann (who derived it theoretically soon after). The symbol $\varepsilon$ represents the emissivity of the object’s surface, which has a value between 0 and 1, depending on the composition of the surface. A surface with the maximum emissivity of 1.0 is said to be a blackbody radiator, but such a surface is an ideal limit and does not occur in nature. Note again that the temperature in Eq. 18-38 must be in kelvins so that a temperature of absolute zero corresponds to no radiation. Note also that every object whose temperature is above 0 K—including you—emits thermal radiation. (See Fig. 18-20.)
The rate $P_{\text{abs}}$ at which an object absorbs energy via thermal radiation from its environment, which we take to be at uniform temperature $T_{\text{env}}$ (in kelvins), is

$$P_{\text{abs}} = \varepsilon \sigma A T_{\text{env}}^4.$$  \hfill (18-39)

The emissivity $\varepsilon$ in Eq. 18-39 is the same as that in Eq. 18-38. An idealized blackbody radiator, with $\varepsilon = 1$, will absorb all the radiated energy it intercepts (rather than sending a portion back away from itself through reflection or scattering).

Because an object both emits and absorbs thermal radiation, its net rate $P_{\text{net}}$ of energy exchange due to thermal radiation is

$$P_{\text{net}} = P_{\text{abs}} - P_{\text{rad}} = \varepsilon \sigma A (T_{\text{env}}^4 - T^4).$$  \hfill (18-40)

$P_{\text{net}}$ is positive if net energy is being absorbed via radiation and negative if it is being lost via radiation.

Thermal radiation is involved in the numerous medical cases of a dead rattlesnake striking a hand reaching toward it. Pits between each eye and nostril of a rattlesnake (Fig. 18-21) serve as sensors of thermal radiation. When, say, a mouse moves close to a rattlesnake’s head, the thermal radiation from the mouse triggers these sensors, causing a reflex action in which the snake strikes the mouse with its fangs and injects its venom. The thermal radiation from a reaching hand can cause the same reflex action even if the snake has been dead for as long as 30 min because the snake’s nervous system continues to function. As one snake expert advised, if you must remove a recently killed rattlesnake, use a long stick rather than your hand.

### Sample Problem 18.06  Thermal conduction through a layered wall

Figure 18-22 shows the cross section of a wall made of white pine of thickness $L_a$ and brick of thickness $L_d$ (= 2.0$L_a$), sandwiching two layers of unknown material with identical thicknesses and thermal conductivities. The thermal conductivity of the pine is $k_a$ and that of the brick is $k_d$ (= 5.0$k_a$). The face area $A$ of the wall is unknown. Thermal conduction through the wall has reached the steady state; the only known interface temperatures are $T_1 = 25^\circ$C, $T_2 = 20^\circ$C, and $T_5 = -10^\circ$C. What is interface temperature $T_4$?

![Figure 18-22](image)

**KEY IDEAS**

1. Temperature $T_4$ helps determine the rate $P_d$ at which energy is conducted through the brick, as given by Eq. 18-32. However, we lack enough data to solve Eq. 18-32 for $T_4$.
2. Because the conduction is steady, the conduction rate $P_d$ through the brick must equal the conduction rate $P_a$ through the pine. That gets us going.

**Calculations:** From Eq. 18-32 and Fig. 18-22, we can write

$$P_a = k_a A \frac{T_1 - T_2}{L_a} \quad \text{and} \quad P_d = k_d A \frac{T_4 - T_5}{L_d}.$$

Setting $P_a = P_d$ and solving for $T_4$ yield

$$T_4 = \frac{k_a L_d}{k_d L_a} (T_1 - T_2) + T_5.$$

Letting $L_d = 2.0 L_a$ and $k_d = 5.0k_a$, and inserting the known temperatures, we find

$$T_4 = \frac{k_a (2.0 L_a)}{(5.0k_a)L_a} (25^\circ C - 20^\circ C) + (-10^\circ C) = -8.0^\circ C.$$

(Answer)
CHAPTER 18  TEMPERATURE, HEAT, AND THE FIRST LAW OF THERMODYNAMICS

KEY IDEAS

(1) In a steady-state situation, a surface with area $A$, emissivity $\varepsilon$, and temperature $T$ loses energy to thermal radiation at the rate given by Eq. 18-38 ($P_{\text{rad}} = \varepsilon \sigma A T^4$). (2) Simultaneously, it gains energy by thermal radiation from its environment at temperature $T_{\text{env}}$ at the rate given by Eq. 18-39 ($P_{\text{env}} = \varepsilon \sigma A T_{\text{env}}^4$).

Calculations: To find the net rate of energy exchange, we subtract Eq. 18-38 from Eq. 18-39 to write

$$P_{\text{net}} = P_{\text{abs}} - P_{\text{rad}} = \varepsilon \sigma A (T_{\text{env}}^4 - T^4).$$

We need the area of the curved surface of the cylinder, which is $A = h(2\pi R)$. We also need the temperatures in kelvins: $T_{\text{env}} = 273 \text{ K} - 3 \text{ K} = 270 \text{ K}$ and $T = 273 \text{ K} + 22 \text{ K} = 295 \text{ K}$. Substituting in Eq. 18-41 for $A$ and then substituting known values in SI units (which are not displayed here), we find

$$P_{\text{net}} = (5.67 \times 10^{-8})(0.80)(0.050)(2\pi)(0.015)(270^4 - 295^4)$$

$$= -0.48 \text{ W}.$$ (Answer)

Thus, the plant has a net loss of energy via thermal radiation of 0.48 W. The plant’s energy production rate is comparable to that of a hummingbird in flight.

Sample Problem 18.07  Thermal radiation by a skunk cabbage can melt surrounding snow

Unlike most other plants, a skunk cabbage can regulate its internal temperature (set at $T = 22^\circ \text{C}$) by altering the rate at which it produces energy. If it becomes covered with snow, it can increase that production so that its thermal radiation melts the snow in order to re-expose the plant to sunlight. Let’s model a skunk cabbage with a cylinder of height $h = 5.0 \text{ cm}$ and radius $R = 1.5 \text{ cm}$ and assume it is surrounded by a snow wall at temperature $T_{\text{env}} = -3.0^\circ \text{C}$ (Fig. 18-23). If the emissivity $\varepsilon$ is 0.80, what is the net rate of energy exchange via thermal radiation between the plant’s curved side and the snow?

Additional examples, video, and practice available at WileyPLUS

Temperature; Thermometers  Temperature is an SI base quantity related to our sense of hot and cold. It is measured with a thermometer, which contains a working substance with a measurable property, such as length or pressure, that changes in a regular way as the substance becomes hotter or colder.

Zeroth Law of Thermodynamics  When a thermometer and some other object are placed in contact with each other, they eventually reach thermal equilibrium. The reading of the thermometer is then taken to be the temperature of the other object. The process provides consistent and useful temperature measurements because of the zeroth law of thermodynamics: If bodies $A$ and $B$ are each in thermal equilibrium with a third body $C$ (the thermometer), then $A$ and $B$ are in thermal equilibrium with each other.

The Kelvin Temperature Scale  In the SI system, temperature is measured on the Kelvin scale, which is based on the triple point of water (273.16 K). Other temperatures are then defined by use of a constant-volume gas thermometer, in which a sample of gas is maintained at constant volume so its pressure is proportional to its temperature. We define the temperature $T$ as measured with a gas thermometer to be

$$T = (273.16 \text{ K}) \lim_{p_{\text{gas}} \to p_3} \left( \frac{p}{p_3} \right).$$

Here $T$ is in kelvins, and $p_3$ and $p$ are the pressures of the gas at 273.16 K and the measured temperature, respectively.

Celsius and Fahrenheit Scales  The Celsius temperature scale is defined by

$$T_C = T - 273.15^\circ,$$

with $T$ in kelvins. The Fahrenheit temperature scale is defined by

$$T_F = \frac{9}{5} T_C + 32^\circ.$$
**Thermal Expansion** All objects change size with changes in temperature. For a temperature change $\Delta T$, a change $\Delta L$ in any linear dimension $L$ is given by

$$\Delta L = L \alpha \Delta T,$$  \hspace{1cm} (18-9)

in which $\alpha$ is the **coefficient of linear expansion**. The change $\Delta V$ in the volume $V$ of a solid or liquid is

$$\Delta V = V \beta \Delta T.$$  \hspace{1cm} (18-10)

Here $\beta = 3\alpha$ is the material’s **coefficient of volume expansion**.

**Heat** Heat $Q$ is energy that is transferred between a system and its environment because of a temperature difference between them. It can be measured in **joules** (J), **calories** (cal), **kilocalories** (Cal or kcal), or **British thermal units** (Btu), with

$$1 \text{ cal} = 3.968 \times 10^{-3} \text{ Btu} = 4.1868 \text{ J}. \hspace{1cm} (18-12)$$

**Heat Capacity and Specific Heat** If heat $Q$ is absorbed by an object, the object’s temperature change $T_f - T_i$ is related to $Q$ by

$$Q = C(T_f - T_i),$$  \hspace{1cm} (18-13)

in which $C$ is the **heat capacity** of the object. If the object has mass $m$, then

$$Q = cm(T_f - T_i),$$  \hspace{1cm} (18-14)

where $c$ is the **specific heat** of the material making up the object. The **molar specific heat** of a material is the heat capacity per mole, which means per $6.02 \times 10^{23}$ elementary units of the material.

**Heat of Transformation** Matter can exist in three common states: solid, liquid, and vapor. Heat absorbed by a material may change the material’s physical state—for example, from solid to liquid or from liquid to gas. The amount of energy required per unit mass to change the state (but not the temperature) of a particular material is its **heat of transformation** $L$. Thus,

$$Q = Lm.$$  \hspace{1cm} (18-16)

The heat of vaporization $L_v$ is the amount of energy per unit mass that must be added to vaporize a liquid or that must be removed to condense a gas. The heat of fusion $L_f$ is the amount of energy per unit mass that must be added to melt a solid or that must be removed to freeze a liquid.

**Work Associated with Volume Change** A gas may exchange energy with its surroundings through work. The amount of work $W$ done by a gas as it expands or contracts from an initial volume $V_i$ to a final volume $V_f$ is given by

$$W = \int dW = \int_{V_i}^{V_f} p \, dV.$$  \hspace{1cm} (18-25)

The integration is necessary because the pressure $p$ may vary during the volume change.

**First Law of Thermodynamics** The principle of conservation of energy for a thermodynamic process is expressed in the **first law of thermodynamics**, which may assume either of the forms

$$\Delta E_{\text{int}} = E_{\text{int},f} - E_{\text{int},i} = Q - W \hspace{1cm} \text{(first law)} \hspace{1cm} (18-26)$$

or

$$dE_{\text{int}} = dQ - dW \hspace{1cm} \text{(first law)} \hspace{1cm} (18-27)$$

$E_{\text{int}}$ represents the internal energy of the material, which depends only on the material’s state (temperature, pressure, and volume). $Q$ represents the energy exchanged as heat between the system and its surroundings; $Q$ is positive if the system absorbs heat and negative if the system loses heat. $W$ is the work done by the system; $W$ is positive if the system expands against an external force from the surroundings and negative if the system contracts because of an external force. $Q$ and $W$ are path dependent; $\Delta E_{\text{int}}$ is path independent.

**Applications of the First Law** The first law of thermodynamics finds application in several special cases:

- **adiabatic processes**: $Q = 0$, $\Delta E_{\text{int}} = -W$
- **constant-volume processes**: $W = 0$, $\Delta E_{\text{int}} = Q$
- **cyclical processes**: $\Delta E_{\text{int}} = 0$, $Q = W$
- **free expansions**: $Q = W = \Delta E_{\text{int}} = 0$

**Conduction, Convection, and Radiation** The rate $P_{\text{cond}}$ at which energy is **conducted** through a slab for which one face is maintained at the higher temperature $T_H$ and the other face is maintained at the lower temperature $T_C$ is

$$P_{\text{cond}} = \frac{Q}{t} = kA \frac{T_H - T_C}{L} \hspace{1cm} (18-32)$$

Here each face of the slab has area $A$, the length of the slab (the distance between the faces) is $L$, and $k$ is the thermal conductivity of the material.

Convection occurs when temperature differences cause an energy transfer by motion within a fluid.

Radiation is an energy transfer via the emission of electromagnetic energy. The rate $P_{\text{rad}}$ at which an object emits energy via thermal radiation is

$$P_{\text{rad}} = \sigma \varepsilon AT^4,$$  \hspace{1cm} (18-38)

where $\sigma = 5.6704 \times 10^{-8} \text{ W/m}^2\text{K}^4$ is the Stefan–Boltzmann constant, $\varepsilon$ is the emissivity of the object’s surface, $A$ is its surface area, and $T$ is its surface temperature (in kelvins). The rate $P_{\text{abs}}$ at which an object absorbs energy via thermal radiation from its environment, which is at the uniform temperature $T_{\text{env}}$ (in kelvins), is

$$P_{\text{abs}} = \sigma \varepsilon AT_{\text{env}}^4.$$  \hspace{1cm} (18-39)
1 The initial length $L$, change in temperature $\Delta T$, and change in length $\Delta L$ of four rods are given in the following table. Rank the rods according to their coefficients of thermal expansion, greatest first.

2 Figure 18-24 shows three linear temperature scales, with the freezing and boiling points of water indicated. Rank the three scales according to the size of one degree on them, greatest first.

3 Materials $A$, $B$, and $C$ are solids that are at their melting temperatures. Material $A$ requires 200 J to melt 4 kg, material $B$ requires 300 J to melt 5 kg, and material $C$ requires 300 J to melt 6 kg. Rank the materials according to their heats of fusion, greatest first.

4 A sample $A$ of liquid water and a sample $B$ of ice, of identical mass, are placed in a thermally insulated container and allowed to come to thermal equilibrium. Figure 18-25a is a sketch of the temperature $T$ of the samples versus time $t$. (a) Is the equilibrium temperature above, below, or at the freezing point of water? (b) In reaching equilibrium, does the liquid partly freeze, fully freeze, or undergo no freezing? (c) Does the ice partly melt, fully melt, or undergo no melting?

5 Question 4 continued: Graphs $b$ through $f$ of Fig. 18-25 are additional sketches of $T$ versus $t$, of which one or more are impossible to produce. (a) Which is impossible and why? (b) In the possible ones, is the equilibrium temperature above, below, or at the freezing point of water? (c) As the possible situations reach equilibrium, does the liquid partly freeze, fully freeze, or undergo no freezing? Does the ice partly melt, fully melt, or undergo no melting?

6 Figure 18-26 shows three different arrangements of materials 1, 2, and 3 to form a wall. The thermal conductivities are $k_1 > k_2 > k_3$. The left side of the wall is 20°C higher than the right side. Rank the arrangements according to (a) the (steady state) rate of energy conduction through the wall and (b) the temperature difference across material 1, greatest first.

7 Figure 18-27 shows two closed cycles on $p$-$V$ diagrams for a gas. The three parts of cycle 1 are of the same length and shape as those of cycle 2. For each cycle, should the cycle be traversed clockwise or counterclockwise if (a) the net work $W$ done by the gas is to be positive and (b) the net energy transferred by the gas as heat $Q$ is to be positive?

8 For which cycle in Fig. 18-27, traversed clockwise, is (a) $W$ greater and (b) $Q$ greater?

9 Three different materials of identical mass are placed one at a time in a special freezer that can extract energy from a material at a certain constant rate. During the cooling process, each material begins in the liquid state and ends in the solid state; Fig. 18-28 shows the temperature $T$ versus time $t$. (a) For material 1, is the specific heat for the solid state greater than or less than that for the solid state? Rank the materials according to (b) freezing-point temperature, (c) specific heat in the liquid state, (d) specific heat in the solid state, and (e) heat of fusion, all greatest first.

10 A solid cube of edge length $r$, a solid sphere of radius $r$, and a solid hemisphere of radius $r$, all made of the same material, are maintained at temperature 300 K in an environment at temperature 350 K. Rank the objects according to the net rate at which thermal radiation is exchanged with the environment, greatest first.

11 A hot object is dropped into a thermally insulated container of water, and the object and water are then allowed to come to thermal equilibrium. The experiment is repeated twice, with different hot objects. All three objects have the same mass and initial temperature, and the mass and initial temperature of the water are the same in the three experiments. For each of the experiments, Fig. 18-29 gives graphs of the temperatures $T$ of the object and the water versus time $t$. Rank the graphs according to the specific heats of the objects, greatest first.
Module 18-1 Temperature

1. Suppose the temperature of a gas is 373.15 K when it is at the boiling point of water. What then is the limiting value of the ratio of the pressure of the gas at that boiling point to its pressure at the triple point of water? (Assume the volume of the gas is the same at both temperatures.)

2. Two constant-volume gas thermometers are assembled, one with nitrogen and the other with hydrogen. Both contain enough gas so that \( p_1 = 80 \text{ kPa} \). (a) What is the difference between the pressures in the two thermometers if both bulbs are in boiling water? (Hint: See Fig. 18-6.) (b) Which gas is at higher pressure?

3. A gas thermometer is constructed of two gas-containing bulbs, each in a water bath, as shown in Fig. 18-30. The pressure difference between the two bulbs is measured by a mercury manometer as shown. Appropriate reservoirs, not shown in the diagram, maintain constant gas volume in the two bulbs. There is no difference in pressure when both baths are at the triple point of water. The pressure difference is 120 torr when one bath is at the triple point and the other is at the boiling point of water. It is 90.0 torr when one bath is at the triple point and the other is at an unknown temperature to be measured. What is the unknown temperature?

Module 18-2 The Celsius and Fahrenheit Scales

4. (a) In 1964, the temperature in the Siberian village of Oymyakon reached \(-71^\circ\text{C}\). What temperature is this on the Fahrenheit scale? (b) The highest officially recorded temperature in the continental United States was 134\(^\circ\text{F}\) in Death Valley, California. What is this temperature on the Celsius scale?

5. At what temperature is the Fahrenheit scale reading equal to (a) twice that of the Celsius scale and (b) half that of the Celsius scale?

6. On a linear X temperature scale, water freezes at \(-125.0^\circ\text{X}\) and boils at 375.0\(^\circ\text{X}\). On a linear Y temperature scale, water freezes at \(-70.00^\circ\text{Y}\) and boils at \(-30.00^\circ\text{Y}\). A temperature of 50.00\(^\circ\text{Y}\) corresponds to what temperature on the X scale?

7. Suppose that on a linear temperature scale \( X \), water boils at \(-53.5^\circ X \) and freezes at \(-170^\circ X \). What is a temperature of 340 K on the X scale? (Approximate water’s boiling point as 373 K.)

Module 18-3 Thermal Expansion

8. At 20\(^\circ\text{C}\), a brass cube has edge length 30 cm. What is the increase in the surface area when it is heated from 20\(^\circ\text{C}\) to 75\(^\circ\text{C}\)?

9. A circular hole in an aluminum plate is 2.725 cm in diameter at 0.000\(^\circ\text{C}\). What is its diameter when the temperature of the plate is raised to 100.0\(^\circ\text{C}\)?

10. An aluminum flagpole is 33 m high. By how much does its length increase as the temperature increases by 15 \(^\circ\text{C}\)?

11. What is the volume of a lead ball at 30.00\(^\circ\text{C}\) if the ball’s volume at 60.00\(^\circ\text{C}\) is 50.00 cm\(^3\)?

12. An aluminum-alloy rod has a length of 10.000 cm at 20.000\(^\circ\text{C}\) and a length of 10.015 cm at the boiling point of water. (a) What is the length of the rod at the freezing point of water? (b) What is the temperature if the length of the rod is 10.009 cm?

13. Find the change in volume of an aluminum sphere with an initial radius of 10 cm when the sphere is heated from 0.0\(^\circ\text{C}\) to 100\(^\circ\text{C}\).

14. When the temperature of a copper coin is raised by 100\(^\circ\text{C}\), its diameter increases by 0.18%. To two significant figures, give the percent increase in (a) the area of a face, (b) the thickness, (c) the volume, and (d) the mass of the coin. (e) Calculate the coefficient of linear expansion of the coin.

15. A steel rod is 3.000 cm in diameter at 25.00\(^\circ\text{C}\). A brass ring has an interior diameter of 2.992 cm at 25.00\(^\circ\text{C}\). At what common temperature will the ring just slide onto the rod?

16. When the temperature of a metal cylinder is raised from 0.0\(^\circ\text{C}\) to 100\(^\circ\text{C}\), its length increases by 0.23%. (a) Find the percent change in density. (b) What is the metal? Use Table 18-2.

17. An aluminum cup of 100 cm\(^3\) capacity is completely filled with glycerin at 22\(^\circ\text{C}\). How much glycerin, if any, will spill out of the cup if the temperature of both the cup and the glycerin is increased to 28\(^\circ\text{C}\)? (The coefficient of volume expansion of glycerin is 5.1 \times 10^{-3}\(^\circ\text{C}^{-1}\)).

18. At 20\(^\circ\text{C}\), a rod is exactly 20.05 cm long on a steel ruler. Both are placed in an oven at 270\(^\circ\text{C}\), where the rod now measures 20.11 cm on the same ruler. What is the coefficient of linear expansion for the material of which the rod is made?

19. A vertical glass tube of length \( L = 1.280 \times 10^3 \text{ m} \) is half filled with a liquid at 20.000 \( \times 10^0 \text{°C} \). How much will the height of the liquid column change when the tube and liquid are heated to 30.000 \( \times 10^0 \text{°C} \)? Use coefficients \( \alpha_{\text{glass}} = 1.000 \times 10^{-5} \text{°C}^{-1} \) and \( \beta_{\text{liquid}} = 4.000 \times 10^{-3} \text{°C}^{-1} \).

20. In a certain experiment, a small radioactive source must move at selected, extremely slow speeds. This motion is accomplished by fastening the source to one end of an aluminum rod and heating the central section of the rod in a controlled way. If the effective heated section of the rod in Fig. 18-31 has length \( d = 2.00 \text{ cm} \), at what constant rate must the temperature of the rod be changed if the source is to move at a constant speed of 100 nm/s?

21. As a result of a temperature rise of 32 \( \text{°C} \), a bar with a crack at its center buckles upward (Fig. 18-32). The fixed distance \( L_0 \) is 3.77 m and the coefficient of linear expansion of the bar is \( 25 \times 10^{-5} \text{°C}^{-1} \). Find the rise \( x \) of the center.
Module 18-4  Absorption of Heat

-22 One way to keep the contents of a garage from becoming too cold on a night when a severe subfreezing temperature is forecast is to put a tub of water in the garage. If the mass of the water is 125 kg and its initial temperature is 20°C, (a) how much energy must the water transfer to its surroundings in order to freeze completely and (b) what is the lowest possible temperature of the water and its surroundings until that happens?

-23 SSM A small electric immersion heater is used to heat 100 g of water for a cup of instant coffee. The heater is labeled “200 watts” (it converts electrical energy to thermal energy at this rate). Calculate the time required to bring all this water from 23.0°C to 100°C, ignoring any heat losses.

-24 A certain substance has a mass per mole of 50.0 g/mol. When 314 J is added as heat to a 30.0 g sample, the sample’s temperature rises from 25.0°C to 45.0°C. What are the (a) specific heat and (b) molar specific heat of this substance? (c) How many moles are in the sample?

-25 A certain diet doctor encourages people to diet by drinking ice water. His theory is that the body must burn off enough fat to raise the temperature of the water from 0.00°C to the body temperature of 37.0°C. How many liters of ice water would have to be consumed to burn off 454 g (about 1 lb) of fat, assuming that burning this much fat requires 3500 Cal to be transferred to the ice water? Why is it not advisable to follow this diet? (One liter = 10³ cm³. The density of water is 1.00 g/cm³.)

-26 What mass of butter, which has a usable energy content of 6.0 Cal/g (= 6000 cal/g), would be equivalent to the change in gravitational potential energy of a 73.0 kg man who ascends from sea level to the top of Mt. Everest, at elevation 8.84 km? Assume that the average g for the ascent is 9.80 m/s².

-27 SSM Calculate the minimum amount of energy, in joules, required to completely melt 130 g of silver initially at 15.0°C.

-28 How much water remains unfrozen after 52.0 kJ is transferred as heat from 260 g of liquid water initially at its freezing point?

-29 In a solar water heater, energy from the Sun is gathered by water that circulates through tubes in a rooftop collector. The solar radiation enters the collector through a transparent cover and warms the water in the tubes; this water is pumped into a holding tank. Assume that the efficiency of the overall system is 20% (that is, 80% of the incident solar energy is lost from the system). What collector area is necessary to raise the temperature of 200 L of water in the tank from 20°C to 40°C in 1.0 h when the intensity of incident sunlight is 700 W/m²?

-30 A 0.400 kg sample is placed in a cooling apparatus that removes energy as heat at a constant rate. Figure 18-33 gives the temperature $T$ of the sample versus time $t$; the horizontal scale is set by $t_1 = 80.0$ min. The sample freezes during the energy removal. The specific heat of the sample in its initial liquid phase is 3000 J/kg·K. What are (a) the sample’s heat of fusion and (b) its specific heat in the frozen phase?

-31 ILW What mass of steam at 100°C must be mixed with 150 g of ice at its melting point, in a thermally insulated container, to produce liquid water at 50°C?

-32 The specific heat of a substance varies with temperature according to the function $c = 0.20 + 0.14T + 0.023T^2$, with $T$ in °C and $c$ in cal/g·K. Find the energy required to raise the temperature of 2.0 g of this substance from 5.0°C to 15°C.

-33 Nonmetric version: (a) How long does a 2.0 × 10³ Btu/h water heater take to raise the temperature of 40 gal of water from 70°F to 100°F? Metric version: (b) How long does a 59 kW water heater take to raise the temperature of 150 L of water from 21°C to 38°C?

-34 Samples A and B are at different initial temperatures when they are placed in a thermally insulated container and allowed to come to thermal equilibrium. Figure 18-34a gives the temperatures $T$ versus time $t$. Sample A has a mass of 5.0 kg; sample B has a mass of 1.5 kg. Figure 18-34b is a general plot for the material of sample B. It shows the temperature change $\Delta T$ that the material undergoes when energy is transferred to it as heat $Q$. The change $\Delta T$ is plotted versus the energy $Q$ per unit mass of the material, and the scale of the vertical axis is set by $\Delta T_s = 4.0$ °C. What is the specific heat of sample A?

-35 An insulated Thermos contains 130 cm³ of hot coffee at 80.0°C. You put in a 12.0 g ice cube at its melting point to cool the coffee. By how many degrees has your coffee cooled once the ice has melted and equilibrium is reached? Treat the coffee as though it were pure water and neglect energy exchanges with the environment.

-36 A 150 g copper bowl contains 220 g of water, both at 20.0°C. A very hot 300 g copper cylinder is dropped into the water, causing the water to boil, with 5.00 g being converted to steam. The final temperature of the system is 100°C. Neglect energy transfers with the environment. (a) How much energy (in calories) is transferred to the water as heat? (b) How much to the bowl? (c) What is the original temperature of the cylinder?

-37 A person makes a quantity of iced tea by mixing 500 g of hot tea (essentially water) with an equal mass of ice at its melting point. Assume the mixture has negligible energy exchanges with its environment. If the tea’s initial temperature is $T_i = 90°C$, when thermal equilibrium is reached what are (a) the mixture’s temperature $T_f$ and (b) the remaining mass $m_f$ of ice? If $T_i = 70°C$, when thermal equilibrium is reached what are (c) $T_f$ and (d) $m_f$?

-38 A 0.530 kg sample of liquid water and a sample of ice are placed in a thermally insulated container. The container also contains a device that transfers energy as heat from the liquid water to the ice at a constant rate $P$, until thermal equilibrium is
reached. The temperatures $T$ of the liquid water and the ice are given in Fig. 18-35 as functions of time $t$; the horizontal scale is set by $t_i = 80.0$ min. (a) What is rate $P$? (b) What is the initial mass of the ice in the container? (c) When thermal equilibrium is reached, what is the mass of the ice produced in this process?

![Figure 18-35 Problem 38.](image)

- **39** Ethanol has a boiling point of 78.0°C, a freezing point of −114°C, a heat of vaporization of 879 kJ/kg, a heat of fusion of 109 kJ/kg, and a specific heat of 2.43 kJ/kg$\cdot$°C. How much energy must be removed from 0.510 kg of ethanol that is initially a gas at 78.0°C so that it becomes a solid at −114°C?

- **40** Calculate the specific heat of a metal from the following data. A container made of the metal has a mass of 3.6 kg and contains 14 kg of water. A 1.8 kg piece of the metal initially at a temperature of 180°C is dropped into the water. The container and water initially have a temperature of 16.0°C, and the final temperature of the entire (insulated) system is 18.0°C.

- **41** (a) Two 50 g ice cubes are dropped into 200 g of water in a thermally insulated container. If the water is initially at 25°C, and the ice comes directly from a freezer at −15°C, what is the final temperature at thermal equilibrium? (b) What is the final temperature if only one ice cube is used?

- **42** A 20.0 g copper ring at 0.000°C has an inner diameter of $D = 2.54000$ cm. An aluminum sphere at 100.0°C has a diameter of $d = 2.54508$ cm. The sphere is put on top of the ring (Fig. 18-36), and the two are allowed to come to thermal equilibrium, with no heat lost to the surroundings. The sphere just passes through the ring at the equilibrium temperature. What is the mass of the sphere?

**Module 18-5 The First Law of Thermodynamics**

- **43** In Fig. 18-37, a gas sample expands from $V_0$ to $4.0V_0$ while its pressure decreases from $p_0$ to $p_0/4.0$. If $V_0 = 1.0$ m$^3$ and $p_0 = 40$ Pa, how much work is done by the gas if its pressure changes with volume via (a) path $A$, (b) path $B$, and (c) path $C$?

- **44** A thermodynamic system is taken from state $A$ to state $B$ to state $C$, and then back to $A$, as shown in the $p$-$V$ diagram of Fig. 18-38a. The vertical scale is set by $V_i = 4.0$ m$^3$. (a)–(g) Complete the table in Fig. 18-38b by inserting a plus sign, a minus sign, or a zero in each indicated cell. (h) What is the net work done by the system as it moves once through the cycle $ABCA$?

![Figure 18-38 Problem 44.](image)

- **45 SSM** A gas within a closed chamber undergoes the cycle shown in the $p$-$V$ diagram of Fig. 18-39. The horizontal scale is set by $V_i = 4.0$ m$^3$. Calculate the net energy added to the system as heat during one complete cycle.

- **46** Suppose 200 J of work is done on a system and 70.0 cal is extracted from the system as heat. In the sense of the first law of thermodynamics, what are the values (including algebraic signs) of (a) $W$, (b) $Q$, and (c) $\Delta E_{\text{int}}$?

- **47 SSM** When a system is taken from state $i$ to state $f$ along path $iaf$ in Fig. 18-40, $Q = 50$ cal and $W = 20$ cal. Along path $ibf$, $Q = 36$ cal. (a) What is $W$ along path $ibf$? (b) If $W = −13$ cal for the return path $fi$, what is $Q$ for this path? (c) If $E_{\text{int},i} = 10$ cal, what is $E_{\text{int},f}$? If $E_{\text{int},b} = 22$ cal, what is $Q$ for (d) path $ib$ and (e) path $bf$?

![Figure 18-40 Problem 47.](image)

- **48** As a gas is held within a closed chamber, it passes through the cycle shown in Fig. 18-41. Determine the energy transferred by the system as heat during constant-pressure process $CA$ if the energy added as heat $Q_{AB}$ during constant-volume process $AB$ is 20.0 J, no energy is transferred as heat during adiabatic process $BC$, and the net work done during the cycle is 15.0 J.

![Figure 18-41 Problem 48.](image)
Figure 18-42 represents a closed cycle for a gas (the figure is not drawn to scale). The change in the internal energy of the gas as it moves from \(a\) to \(c\) along the path \(abc\) is \(-200\) J. As it moves from \(c\) to \(d\), \(180\) J must be transferred to it as heat. An additional transfer of \(80\) J to it as heat is needed as it moves from \(d\) to \(a\). How much work is done on the gas as it moves from \(c\) to \(d\)?

A lab sample of gas is taken through cycle \(abc\) shown in the \(p-V\) diagram of Fig. 18-43. The net work done is \(+1.2\) J. Along path \(ab\), the change in the internal energy is \(+3.0\) J and the magnitude of the work done is \(5.0\) J. Along path \(ca\), the energy transferred to the gas as heat is \(+2.5\) J. How much energy is transferred as heat along (a) path \(ab\) and (b) path \(bc\)?

**Module 18-6 Heat Transfer Mechanisms**

A sphere of radius \(0.500\) m, temperature \(27.0°C\), and emissivity \(0.850\) is located in an environment of temperature \(77.0°C\). At what rate does the sphere (a) emit and (b) absorb thermal radiation? (c) What is the sphere’s net rate of energy exchange?

The ceiling of a single-family dwelling in a cold climate should have an \(R\)-value of 30. To give such insulation, how thick would a layer of (a) polyurethane foam and (b) silver have to be?

Consider the slab shown in Fig. 18-18. Suppose that \(L = 25.0\) cm, \(A = 90.0\) cm\(^2\), and the material is copper. If \(T_H = 125°C\), \(T_C = 10.0°C\), and a steady state is reached, find the conduction rate through the slab.

If you were to walk briefly in space without a spacesuit while far from the Sun (as an astronaut does in the movie 2001, A Space Odyssey), you would feel the cold of space—while you radiated energy, you would absorb almost none from your environment. (a) At what rate would you lose energy? (b) How much energy would you lose in 30 s? Assume that your emissivity is 0.90, and estimate other data needed in the calculations.

A cylindrical copper rod of length \(1.2\) m and cross-sectional area \(4.8\) cm\(^2\) is insulated along its side. The ends are held at a temperature difference of \(100°C\) by having one end in a water–ice mixture and the other in a mixture of boiling water and steam. At what rate (a) is energy conducted by the rod and (b) does the ice melt?

The giant hornet Vespa mandarinia japonica preys on Japanese bees. However, if one of the hornets attempts to invade a beehive, several hundred of the bees quickly form a compact ball around the hornet to stop it. They don’t sting, bite, crush, or suffocate it. Rather they overheat it by quickly raising their body temperatures from the normal \(35°C\) to \(47°C\) or \(48°C\), which is lethal to the hornet but not to the bees (Fig. 18-44). Assume the following: 500 bees form a ball of radius \(R = 2.0\) cm for a time \(t = 20\) min, the primary loss of energy by the ball is by thermal radiation, the ball’s surface has emissivity \(e = 0.80\), and the ball has a uniform temperature. On average, how much additional energy must each bee produce during the 20 min to maintain \(47°C\)?

(a) What is the rate of energy loss in watts per square meter through a glass window \(3.0\) mm thick if the outside temperature is \(-20°F\) and the inside temperature is \(+72°F\)? (b) A storm window having the same thickness of glass is installed parallel to the first window, with an air gap of \(7.5\) cm between the two windows. What now is the rate of energy loss if conduction is the only important energy-loss mechanism?

A solid cylinder of radius \(r_1 = 2.5\) cm, length \(h_1 = 5.0\) cm, emissivity 0.85, and temperature \(30°C\) is suspended in an environment of temperature \(50°C\). (a) What is the cylinder’s net thermal radiation transfer rate \(P_R\)? (b) If the cylinder is stretched until its radius is \(r_2 = 0.50\) cm, its net thermal radiation transfer rate becomes \(P_R'\). What is the ratio \(P_R/P_R'\)?

In Fig. 18-45a, two identical rectangular rods of metal are welded end to end, with a temperature of \(T_1 = 0°C\) on the left side and a temperature of \(T_2 = 100°C\) on the right side. In 2.0 min, 10 J is conducted at a constant rate from the right side to the left side. How much time would be required to conduct 10 J if the rods were welded side to side as in Fig. 18-45b?

Figure 18-46 shows the cross section of a wall made of three layers. The layer thicknesses are \(L_1, L_2 = 0.700L_1, 0.350L_1\). The thermal conductivities are \(k_1, k_2 = 0.900k_1, 0.800k_1\). The temperatures at the left side and right side of the wall are \(T_H = 30.0°C\) and \(T_C = -15.0°C\), respectively. Thermal conduction is steady. (a) What is the temperature difference \(\Delta T_2\) across layer 2 (between the left and right sides of the layer)? If \(k_2\) were, instead, equal to \(1.1k_1\), (b) would the rate at which energy is conducted through the wall be greater than, less than, or the same as previously, and (c) what would be the value of \(\Delta T_2\)?

A 5.0 cm slab has formed on an outdoor tank of water (Fig. 18-47). The air is at \(-10°C\). Find the rate of ice formation (centimeters per hour). The ice has thermal conductivity \(0.0040\) cal/s · cm · °C and density \(0.92\) g/cm\(^3\). Assume there is no energy transfer through the walls or bottom.
**62 Leidenfrost effect.** A water drop will last about 1 s on a hot skillet with a temperature between 100°C and about 200°C. However, if the skillet is much hotter, the drop can last several minutes, an effect named after an early investigator. The longer lifetime is due to the support of a thin layer of air and water vapor that separates the drop from the metal (by distance L in Fig. 18-48). Let L = 0.100 mm, and assume that the drop is flat with height h = 1.50 mm and bottom face area \( A = 4.00 \times 10^{-7} \) m². Also assume that the skillet has a constant temperature \( T_s = 300°C \) and the drop has a temperature of 100°C. Water has density \( \rho = 1000 \) kg/m³, and the supporting layer has thermal conductivity \( k = 0.026 \) W/m·K. (a) At what rate is energy conducted from the skillet to the drop through the drop's bottom surface? (b) If conduction is the primary way energy moves from the skillet to the drop, how long will the drop last?

**63** Figure 18-49 shows (in cross section) a wall consisting of four layers, with thermal conductivities \( k_1 = 0.060 \) W/m·K, \( k_2 = 0.040 \) W/m·K, \( k_3 = 0.12 \) W/m·K, and \( k_4 = 0.40 \) W/m·K (\( k_2 \) is not known). The layer thicknesses are \( L_1 = 1.5 \) cm, \( L_2 = 2.8 \) cm, and \( L_3 = 3.5 \) cm (\( L_4 \) is not known). The known temperatures are \( T_1 = 30°C \), \( T_{12} = 25°C \), and \( T_4 = -10°C \). Energy transfer through the wall is steady. What is interface temperature \( T_{34} \)?

**64 Penguin huddling.** To withstand the harsh weather of the Antarctic, emperor penguins huddle in groups (Fig. 18-50). Assume that a penguin is a circular cylinder with a top surface area \( a = 0.34 \) m² and height \( h = 1.1 \) m. Let \( P_r \) be the rate at which an individual penguin radiates energy to the environment (through the top and the sides); thus \( N P_r \) is the rate at which \( N \) identical, well-separated penguins radiate. If the penguins huddle closely to form a huddled cylinder with top surface area \( Na \) and height \( h \), the cylinder radiates at the rate \( P_r \). If \( N = 1000 \), (a) what is the value of the fraction \( N P_r/Na \), and (b) by what percentage does huddling reduce the total radiation loss?

**65** Ice has formed on a shallow pond, and a steady state has been reached, with the air above the ice at −5.0°C and the bottom of the pond at 4.0°C. If the total depth of ice + water is 1.4 m, how thick is the ice? (Assume that the thermal conductivities of ice and water are 0.40 and 0.12 cal/m·°C·s, respectively.)

**66 Evaporative cooling of beverages.** A cold beverage can be kept cold even on a warm day if it is slipped into a porous ceramic container that has been soaked in water. Assume that energy lost to evaporation matches the net energy gained via the radiation exchange through the top and side surfaces. The container and beverage have temperature \( T = 15°C \), the environment has temperature \( T_{env} = 32°C \), and the container is a cylinder with radius \( r = 2.2 \) cm and height 10 cm. Approximate the emissivity as \( \varepsilon = 1 \), and neglect other energy exchanges. At what rate \( dm/dt \) is the container losing water mass?

### Additional Problems

**67** In the extrusion of cold chocolate from a tube, work is done on the chocolate by the pressure applied by a ram forcing the chocolate through the tube. The work per unit mass of extruded chocolate is equal to \( p/\rho \), where \( p \) is the difference between the applied pressure and the pressure where the chocolate emerges from the tube, and \( \rho \) is the density of the chocolate. Rather than increasing the temperature of the chocolate, this work melts cocoa fats in the chocolate. These fats have a heat of fusion of 150 kJ/kg. Assume that all of the work goes into that melting and that these fats make up 30% of the chocolate’s mass. What percentage of the fats melt during the extrusion if \( p = 5.5 \) MPa and \( \rho = 1200 \) kg/m³?

**68** Icebergs in the North Atlantic present hazards to shipping, causing the lengths of shipping routes to be increased by about 30% during the iceberg season. Attempts to destroy icebergs include planting explosives, bombing, torpedoing, shelling, ramming, and coating with black soot. Suppose that direct melting of the iceberg, by placing heat sources in the ice, is tried. How much energy as heat is required to melt 10% of an iceberg that has a mass of 200 000 metric tons? (Use 1 metric ton = 1000 kg.)

**69** Figure 18-51 displays a closed cycle for a gas. The change in internal energy along path \( ca \) is −160 J. The energy transferred to the gas as heat is 200 J along path \( ab \), and 40 J along path \( bc \). How much work is done by the gas along (a) path \( abc \) and (b) path \( ab \)?

**70** In a certain solar house, energy from the Sun is stored in barrels filled with water. In a particular winter stretch of five cloudy days, 1.00 \( \times 10^6 \) kcal is needed to maintain the inside of the house at 22.0°C. Assuming that the water in the barrels is at 50.0°C and that the water has a density of 1.00 \( \times 10^3 \) kg/m³, what volume of water is required?

**71** A 0.300 kg sample is placed in a cooling apparatus that removes energy as heat at a constant rate of 2.81 W. Figure 18-52 gives the temperature \( T \) of the sam-

---

Additional Problems

67 In the extrusion of cold chocolate from a tube, work is done on the chocolate by the pressure applied by a ram forcing the chocolate through the tube. The work per unit mass of extruded chocolate is equal to \( p/\rho \), where \( p \) is the difference between the applied pressure and the pressure where the chocolate emerges from the tube, and \( \rho \) is the density of the chocolate. Rather than increasing the temperature of the chocolate, this work melts cocoa fats in the chocolate. These fats have a heat of fusion of 150 kJ/kg. Assume that all of the work goes into that melting and that these fats make up 30% of the chocolate’s mass. What percentage of the fats melt during the extrusion if \( p = 5.5 \) MPa and \( \rho = 1200 \) kg/m³?

68 Icebergs in the North Atlantic present hazards to shipping, causing the lengths of shipping routes to be increased by about 30% during the iceberg season. Attempts to destroy icebergs include planting explosives, bombing, torpedoing, shelling, ramming, and coating with black soot. Suppose that direct melting of the iceberg, by placing heat sources in the ice, is tried. How much energy as heat is required to melt 10% of an iceberg that has a mass of 200 000 metric tons? (Use 1 metric ton = 1000 kg.)

69 Figure 18-51 displays a closed cycle for a gas. The change in internal energy along path \( ca \) is −160 J. The energy transferred to the gas as heat is 200 J along path \( ab \), and 40 J along path \( bc \). How much work is done by the gas along (a) path \( abc \) and (b) path \( ab \)?

70 In a certain solar house, energy from the Sun is stored in barrels filled with water. In a particular winter stretch of five cloudy days, 1.00 \( \times 10^6 \) kcal is needed to maintain the inside of the house at 22.0°C. Assuming that the water in the barrels is at 50.0°C and that the water has a density of 1.00 \( \times 10^3 \) kg/m³, what volume of water is required?

71 A 0.300 kg sample is placed in a cooling apparatus that removes energy as heat at a constant rate of 2.81 W. Figure 18-52 gives the temperature \( T \) of the sam-
ple versus time \( t \). The temperature scale is set by \( T_i = 30^\circ \text{C} \) and the time scale is set by \( t_i = 20 \text{ min} \). What is the specific heat of the sample?

72 The average rate at which energy is conducted outward through the ground surface in North America is 54.0 mW/m², and the average thermal conductivity of the near-surface rocks is 2.50 W/m·K. Assuming a surface temperature of 10.0°C, find the temperature at a depth of 35.0 km (near the base of the crust). Ignore the heat generated by the presence of radioactive elements.

73 What is the temperature of the water?

74 In a series of experiments, block \( B \) is to be placed in a thermally insulated container with block \( A \), which has the same mass as block \( B \). In each experiment, block \( B \) is initially at a certain temperature \( T_B \), but temperature \( T_A \) of block \( A \) is changed from experiment to experiment. Let \( T_f \) represent the final temperature of the two blocks when they reach thermal equilibrium in any of the experiments. Figure 18-53 gives temperature \( T_f \) versus the initial temperature \( T_A \) for a range of possible values of \( T_A \), from \( T_{A1} = 0 \) K to \( T_{A2} = 500 \) K. The vertical axis scale is set by \( T_{B1} = 400 \) K. What are (a) temperature \( T_B \) and (b) the ratio \( c_p/c_A \) of the specific heats of the blocks?

75 Figure 18-54 displays a closed cycle for a gas. From \( c \) to \( b \), 40 J is transferred from the gas as heat. From \( b \) to \( a \), 130 J is transferred from the gas as heat, and the magnitude of the work done by the gas is 80 J. From \( a \) to \( c \), 400 J is transferred to the gas as heat. What is the work done by the gas from \( a \) to \( c \)? (Hint: You need to supply the plus and minus signs for the given data.)

76 Three equal-length straight rods, of aluminum, Invar, and steel, all at 20.0°C, form an equilateral triangle with hinge pins at the vertices. At what temperature will the angle opposite the Invar rod be 59.95°? See Appendix E for needed trigonometric formulas and Table 18-2 for needed data.

77 A sample of gas undergoes a transition from an initial state \( a \) to a final state \( b \) by three different paths (processes), as shown in the \( p-V \) diagram in Fig. 18-57, where \( V_b = 5.00V_a \). The energy transferred to the gas as heat in process 1 is \( 10p_iV_i \). In terms of \( p_iV_i \), what are (a) the energy transferred to the gas as heat in process 2 and (b) the change in internal energy that the gas undergoes in process 3?

80 Figure 18-56a shows a cylinder containing gas and closed by a movable piston. The cylinder is kept submerged in an ice–water mixture. The piston is quickly pushed down from position 1 to position 2 and then held at position 2 until the gas is again at the temperature of the ice–water mixture; it then is slowly raised back to position 1. Figure 18-56b is a \( p-V \) diagram for the process. If 100 g of ice is melted during the cycle, how much work has been done on the gas?
84 (a) Calculate the rate at which body heat is conducted through the clothing of a skier in a steady-state process, given the following data: the body surface area is 1.8 m², and the clothing is 1.0 cm thick; the skin surface temperature is 33°C and the outer surface of the clothing is at 10°C; the thermal conductivity of the clothing is 0.040 W/m·K. (b) If, after a fall, the skier’s clothes became soaked with water of thermal conductivity 0.60 W/m·K, by how much is the rate of conduction multiplied?

85 SSM A 2.50 kg lump of aluminum is heated to 92.0°C and then dropped into 8.00 kg of water at 5.00°C. Assuming that the lump–water system is thermally isolated, what is the system’s equilibrium temperature?

86 A glass window pane is exactly 20 cm by 30 cm at 10°C. By how much has its area increased when its temperature is 40°C, assuming that it can expand freely?

87 A recruit can join the semi-secret “300 F” club at the Amundsen–Scott South Pole Station only when the outside temperature is below −70°C. On such a day, the recruit first basks in a hot sauna and then runs outside wearing only shoes. (This is, of course, extremely dangerous, but the rite is effectively a protest against the constant danger of the cold.)

Assume that upon stepping out of the sauna, the recruit’s skin temperature is 102°F and the walls, ceiling, and floor of the sauna room have a temperature of 30°C. Estimate the recruit’s surface area, and take the skin emissivity to be 0.80. (a) What is the approximate net rate $P_{\text{net}}$ at which the recruit loses energy via thermal radiation exchanges with the room? Next, assume that when outdoors, half the recruit’s surface area exchanges thermal radiation with the sky at a temperature of −25°C and the other half exchanges thermal radiation with the snow and ground at a temperature of −80°C. What is the approximate net rate at which the recruit loses energy via thermal radiation exchanges with (b) the sky and (c) the snow and ground?

88 A steel rod at 25.0°C is bolted at both ends and then cooled. At what temperature will it rupture? Use Table 12-1.

89 An athlete needs to lose weight and decides to do it by “pumping iron.” (a) How many times must an 80.0 kg weight be lifted a distance of 1.00 m in order to burn off 1.00 lb of fat, assuming that much fat is equivalent to 3500 Cal? (b) If the weight is lifted once every 2.00 s, how long does the task take?

90 Soon after Earth was formed, heat released by the decay of radioactive elements raised the average internal temperature from 300 to 3000 K, at about which value it remains today. Assuming an average coefficient of volume expansion of $3.0 \times 10^{-5} \text{K}^{-1}$, by how much has the radius of Earth increased since the planet was formed?

91 It is possible to melt ice by rubbing one block of it against another. How much work, in joules, would you have to do to get 1.00 g of ice to melt?

92 A rectangular plate of glass initially has the dimensions 0.200 m by 0.300 m. The coefficient of linear expansion for the glass is $9.00 \times 10^{-6} \text{K}^{-1}$. What is the change in the plate’s area if its temperature is increased by 20.0 K?

93 Suppose that you intercept $5.0 \times 10^{-3}$ of the energy radiated by a hot sphere that has a radius of 0.020 m, an emissivity of 0.80, and a surface temperature of 500 K. How much energy do you intercept in 2.0 min?

94 A thermometer of mass 0.0550 kg and of specific heat 0.837 kJ/kg·K reads 15.0°C. It is then completely immersed in 0.300 kg of water, and it comes to the same final temperature as the water. If the thermometer then reads 44.4°C, what was the temperature of the water before insertion of the thermometer?

95 A sample of gas expands from $V_1 = 1.0 \text{ m}^3$ and $p_1 = 40 \text{ Pa}$ to $V_2 = 4.0 \text{ m}^3$ and $p_2 = 10 \text{ Pa}$ along path $B$ in the $p$-$V$ diagram in Fig. 18-58. It is then compressed back to $V_1$ along either path $A$ or path $C$. Compute the net work done by the gas for the complete cycle along (a) path $BA$ and (b) path $BC$. Figure 18-58 Problem 95.

96 Figure 18-59 shows a composite bar of length $L = L_1 + L_2$ and consisting of two materials. One material has length $L_1$ and coefficient of linear expansion $\alpha_1$; the other has length $L_2$ and coefficient of linear expansion $\alpha_2$. (a) What is the coefficient of linear expansion $\alpha$ for the composite bar? For a particular composite bar, $L$ is 52.4 cm, material 1 is steel, and material 2 is brass. If $\alpha = 1.3 \times 10^{-5}/\text{C}$, what are the lengths (b) $L_1$ and (c) $L_2$?

97 On finding your stove out of order, you decide to boil the water for a cup of tea by shaking it in a thermos flask. Suppose that you use tap water at 19°C, the water falls 32 cm each shake, and you make 27 shakes each minute. Neglecting any loss of thermal energy by the flask, how long (in minutes) must you shake the flask until the water reaches 100°C?

98 The $p$-$V$ diagram in Fig. 18-60 shows two paths along which a sample of gas can be taken from state $a$ to state $b$, where $V_b = 3.0V_1$. Path 1 requires that energy equal to $5.0p_1V_1$ be transferred to the gas as heat. Path 2 requires that energy equal to $5.5p_1V_1$ be transferred to the gas as heat. What is the ratio $p_2/p_1$?

99 A cube of edge length $6.0 \times 10^{-6}$ m, emissivity 0.75, and temperature $-100\degree$C floats in an environment at $-150\degree$C. What is the cube’s net thermal radiation transfer rate?

100 A flow calorimeter is a device used to measure the specific heat of a liquid. Energy is added as heat at a known rate to a stream of the liquid as it passes through the calorimeter at a known rate. Measurement of the resulting temperature difference between the inflow and the outflow points of the liquid stream enables us to compute the specific heat of the liquid. Suppose a liquid of density 0.85 g/cm³ flows through a calorimeter at the rate of 8.0 cm³/s. When energy is added at the rate of 250 W by means of an electric heating coil, a temperature difference of 15°C is established in steady-state conditions between the inflow and the outflow points. What is the specific heat of the liquid?

101 An object of mass 6.00 kg falls through a height of 50.0 m and, by means of a mechanical linkage, rotates a paddle wheel that stirs 0.600 kg of water. Assume that the initial gravitational potential energy of the object is fully transferred to thermal energy of the water, which is initially at 15.0°C. What is the temperature rise of the water?
The Pyrex glass mirror in a telescope has a diameter of 170 in. The temperature ranges from \(-16^\circ\text{C}\) to \(32^\circ\text{C}\) on the location of the telescope. What is the maximum change in the diameter of the mirror, assuming that the glass can freely expand and contract?

The area \(A\) of a rectangular plate is \(ab = 1.4 \text{ m}^2\). Its coefficient of linear expansion is \(a = 32 \times 10^{-6}/\text{C}\). After a temperature rise \(\Delta T = 89^\circ\text{C}\), side \(a\) is longer by \(\Delta a\) and side \(b\) is longer by \(\Delta b\) (Fig. 18-61). Neglecting the small quantity \((\Delta a \Delta b)/ab\), find \(\Delta A\).

Consider the liquid in a barometer whose coefficient of volume expansion is \(6.6 \times 10^{-4}/\text{C}\). Find the relative change in the liquid’s height if the temperature changes by \(12^\circ\text{C}\) while the pressure remains constant. Neglect the expansion of the glass tube.

A pendulum clock with a pendulum made of brass is designed to keep accurate time at \(23^\circ\text{C}\). Assume it is a simple pendulum consisting of a bob at one end of a brass rod of negligible mass that is pivoted about the other end. If the clock operates at \(0.0^\circ\text{C}\), (a) does it run too fast or too slow, and (b) what is the magnitude of its error in seconds per hour?

A room is lighted by four 100 W incandescent lightbulbs. (The power of 100 W is the rate at which a bulb converts electrical energy to heat and the energy of visible light.) Assuming that 73\% of the energy is converted to heat, how much heat does the room receive in 6.9 h?

An energetic athlete can use up all the energy from a diet of 4000 Cal/day. If he were to use up this energy at a steady rate, what is the ratio of the rate of energy use compared to that of a 100 W bulb? (The power of 100 W is the rate at which the bulb converts electrical energy to heat and the energy of visible light.)

A 1700 kg Buick moving at 83 km/h brakes to a stop, at uniform deceleration and without skidding, over a distance of 93 m. At what average rate is mechanical energy transferred to thermal energy in the brake system?
CHAPTER 19

The Kinetic Theory of Gases

19-1 AVOGADRO’S NUMBER

Learning Objectives

After reading this module, you should be able to . . .

19.01 Identify Avogadro’s number \( N_A \).
19.02 Apply the relationship between the number of moles \( n \), the number of molecules \( N \), and Avogadro’s number \( N_A \).
19.03 Apply the relationships between the mass \( m \) of a sample, the molar mass \( M \) of the molecules in the sample, the number of moles \( n \) in the sample, and Avogadro’s number \( N_A \).

Key Ideas

- The kinetic theory of gases relates the macroscopic properties of gases (for example, pressure and temperature) to the microscopic properties of gas molecules (for example, speed and kinetic energy).
- One mole of a substance contains \( N_A \) (Avogadro’s number) elementary units (usually atoms or molecules), where \( N_A \) is found experimentally to be \( N_A = 6.02 \times 10^{23} \text{ mol}^{-1} \) (Avogadro’s number).

One molar mass \( M \) of any substance is the mass of one mole of the substance.

- A mole is related to the mass \( m \) of the individual molecules of the substance by \( M = mN_A \).
- The number of moles \( n \) contained in a sample of mass \( M_{\text{sam}} \) consisting of \( N \) molecules, is related to the molar mass \( M \) of the molecules and to Avogadro’s number \( N_A \) as given by \( n = \frac{N}{N_A} = \frac{M_{\text{sam}}}{M} = \frac{M_{\text{sam}}}{mN_A} \).

What Is Physics?

One of the main subjects in thermodynamics is the physics of gases. A gas consists of atoms (either individually or bound together as molecules) that fill their container’s volume and exert pressure on the container’s walls. We can usually assign a temperature to such a contained gas. These three variables associated with a gas—volume, pressure, and temperature—are all a consequence of the motion of the atoms. The volume is a result of the freedom the atoms have to spread throughout the container, the pressure is a result of the collisions of the atoms with the container’s walls, and the temperature has to do with the kinetic energy of the atoms. The kinetic theory of gases, the focus of this chapter, relates the motion of the atoms to the volume, pressure, and temperature of the gas.

Applications of the kinetic theory of gases are countless. Automobile engineers are concerned with the combustion of vaporized fuel (a gas) in the automobile engines. Food engineers are concerned with the production rate of the fermentation gas that causes bread to rise as it bakes. Beverage engineers are concerned with how gas can produce the head in a glass of beer or shoot a cork from a champagne bottle. Medical engineers and physiologists are concerned with calculating how long a scuba diver must pause during ascent to eliminate nitrogen gas from the bloodstream (to avoid the bends). Environmental scientists are concerned with how heat exchanges between the oceans and the atmosphere can affect weather conditions.

The first step in our discussion of the kinetic theory of gases deals with measuring the amount of a gas present in a sample, for which we use Avogadro’s number.
Avogadro’s Number

When our thinking is slanted toward atoms and molecules, it makes sense to measure the sizes of our samples in moles. If we do so, we can be certain that we are comparing samples that contain the same number of atoms or molecules. The *mole* is one of the seven SI base units and is defined as follows:

One mole is the number of atoms in a 12 g sample of carbon-12.

The obvious question now is: “How many atoms or molecules are there in a mole?” The answer is determined experimentally and, as you saw in Chapter 18, is

$$N_A = 6.02 \times 10^{23} \text{ mol}^{-1}$$

(Avogadro’s number),

where mol$^{-1}$ represents the inverse mole or “per mole,” and mol is the abbreviation for mole. The number $N_A$ is called *Avogadro’s number* after Italian scientist Amedeo Avogadro (1776 – 1856), who suggested that all gases occupying the same volume under the same conditions of temperature and pressure contain the same number of atoms or molecules.

The number of moles $n$ contained in a sample of any substance is equal to the ratio of the number of molecules $N$ in the sample to the number of molecules $N_A$ in 1 mol:

$$n = \frac{N}{N_A}.$$  \hfill (19-2)

(Caution: The three symbols in this equation can easily be confused with one another, so you should sort them with their meanings now, before you end in “N-confusion.”) We can find the number of moles $n$ in a sample from the mass $M_{\text{sam}}$ of the sample and either the molar mass $M$ (the mass of 1 mol) or the molecular mass $m$ (the mass of one molecule):

$$n = \frac{M_{\text{sam}}}{M} = \frac{M_{\text{sam}}}{mN_A}.$$  \hfill (19-3)

In Eq. 19-3, we used the fact that the mass $M$ of 1 mol is the product of the mass $m$ of one molecule and the number of molecules $N_A$ in 1 mol:

$$M = mN_A.$$  \hfill (19-4)

19-2 IDEAL GASES

Learning Objectives

*After reading this module, you should be able to . . .*

19.04 Identify why an ideal gas is said to be ideal.
19.05 Apply either of the two forms of the ideal gas law, written in terms of the number of moles $n$ or the number of molecules $N$.
19.06 Relate the ideal gas constant $R$ and the Boltzmann constant $k$.
19.07 Identify that the temperature in the ideal gas law must be in kelvins.
19.08 Sketch $p$-$V$ diagrams for a constant-temperature expansion of a gas and a constant-temperature contraction.
19.09 Identify the term isotherm.
19.10 Calculate the work done by a gas, including the algebraic sign, for an expansion and a contraction along an isotherm.
19.11 For an isothermal process, identify that the change in internal energy $\Delta E$ is zero and that the energy $Q$ transferred as heat is equal to the work $W$ done.
19.12 On a $p$-$V$ diagram, sketch a constant-volume process and identify the amount of work done in terms of area on the diagram.
19.13 On a $p$-$V$ diagram, sketch a constant-pressure process and determine the work done in terms of area on the diagram.
Key Ideas

- An ideal gas is one for which the pressure $p$, volume $V$, and temperature $T$ are related by
  \[ pV = nRT \] (ideal gas law).

Here $n$ is the number of moles of the gas present and $R$ is a constant (8.31 J/mol · K) called the gas constant.

- The ideal gas law can also be written as
  \[ pV = NkT, \]

where the Boltzmann constant $k$ is
  \[ k = \frac{R}{N_A} = 1.38 \times 10^{-23} \text{ J/K}. \]

- The work done by an ideal gas during an isothermal (constant-temperature) change from volume $V_i$ to volume $V_f$ is
  \[ W = nRT \ln \frac{V_f}{V_i} \] (ideal gas, isothermal process).

Ideal Gases

Our goal in this chapter is to explain the macroscopic properties of a gas—such as its pressure and its temperature—in terms of the behavior of the molecules that make it up. However, there is an immediate problem: which gas? Should it be hydrogen, oxygen, or methane, or perhaps uranium hexafluoride? They are all different. Experimenters have found, though, that if we confine 1 mol samples of various gases in boxes of identical volume and hold the gases at the same temperature, then their measured pressures are almost the same, and at lower densities the differences tend to disappear. Further experiments show that, at low enough densities, all real gases tend to obey the relation

\[ pV = nRT \] (ideal gas law),

in which $p$ is the absolute (not gauge) pressure, $n$ is the number of moles of gas present, and $T$ is the temperature in kelvins. The symbol $R$ is a constant called the gas constant that has the same value for all gases—namely,

\[ R = 8.31 \text{ J/mol} \cdot \text{K}. \] (19-6)

Equation 19-5 is called the ideal gas law. Provided the gas density is low, this law holds for any single gas or for any mixture of different gases. (For a mixture, $n$ is the total number of moles in the mixture.)

We can rewrite Eq. 19-5 in an alternative form, in terms of a constant called the Boltzmann constant $k$, which is defined as

\[ k = \frac{R}{N_A} = \frac{8.31 \text{ J/mol} \cdot \text{K}}{6.02 \times 10^{23} \text{ mol}^{-1}} = 1.38 \times 10^{-23} \text{ J/K}. \] (19-7)

This allows us to write $R = kN_A$. Then, with Eq. 19-2 ($n = N/N_A$), we see that

\[ nR = Nk. \] (19-8)

Substituting this into Eq. 19-5 gives a second expression for the ideal gas law:

\[ pV = NkT \] (ideal gas law),

(Caution: Note the difference between the two expressions for the ideal gas law—Eq. 19-5 involves the number of moles $n$, and Eq. 19-9 involves the number of molecules $N$.)

You may well ask, “What is an ideal gas, and what is so ‘ideal’ about it?” The answer lies in the simplicity of the law (Eqs. 19-5 and 19-9) that governs its macroscopic properties. Using this law—as you will see—we can deduce many properties of the ideal gas in a simple way. Although there is no such thing in nature as a truly ideal gas, all real gases approach the ideal state at low enough densities—that is, under conditions in which their molecules are far enough apart that they do not interact with one another. Thus, the ideal gas concept allows us to gain useful insights into the limiting behavior of real gases.
Figure 19-1 gives a dramatic example of the ideal gas law. A stainless-steel tank with a volume of 18 m$^3$ was filled with steam at a temperature of 110°C through a valve at one end. The steam supply was then turned off and the valve closed, so that the steam was trapped inside the tank (Fig. 19-1a). Water from a fire hose was then poured onto the tank to rapidly cool it. Within less than a minute, the enormously sturdy tank was crushed (Fig. 19-1b), as if some giant invisible creature from a grade B science fiction movie had stepped on it during a rampage.

Actually, it was the atmosphere that crushed the tank. As the tank was cooled by the water steam, the steam cooled and much of it condensed, which means that the number $N$ of gas molecules and the temperature $T$ of the gas inside the tank both decreased. Thus, the right side of Eq. 19-9 decreased, and because volume $V$ was constant, the gas pressure $p$ on the left side also decreased. The gas pressure decreased so much that the external atmospheric pressure was able to crush the tank’s steel wall. Figure 19-1 was staged, but this type of crushing sometimes occurs in industrial accidents (photos and videos can be found on the web).

Work Done by an Ideal Gas at Constant Temperature

Suppose we put an ideal gas in a piston–cylinder arrangement like those in Chapter 18. Suppose also that we allow the gas to expand from an initial volume $V_i$ to a final volume $V_f$ while we keep the temperature $T$ of the gas constant. Such a process, at constant temperature, is called an isothermal expansion (and the reverse is called an isothermal compression).

On a $p-V$ diagram, an isotherm is a curve that connects points that have the same temperature. Thus, it is a graph of pressure versus volume for a gas whose temperature $T$ is held constant. For $n$ moles of an ideal gas, it is a graph of the equation

$$p = nRT \frac{1}{V} = (\text{a constant}) \frac{1}{V}. \quad (19-10)$$

Figure 19-2 shows three isotherms, each corresponding to a different (constant) value of $T$. (Note that the values of $T$ for the isotherms increase upward to the right.) Superimposed on the middle isotherm is the path followed by a gas during an isothermal expansion from state $i$ to state $f$ at a constant temperature of 310 K.

To find the work done by an ideal gas during an isothermal expansion, we start with Eq. 18-25,

$$W = \int_{V_i}^{V_f} p\,dV. \quad (19-11)$$

This is a general expression for the work done during any change in volume of any gas. For an ideal gas, we can use Eq. 19-5 ($pV = nRT$) to substitute for $p$, obtaining

$$W = \int_{V_i}^{V_f} \frac{nRT}{V} \,dV. \quad (19-12)$$

Because we are considering an isothermal expansion, $T$ is constant, so we can move it in front of the integral sign to write

$$W = nRT \int_{V_i}^{V_f} \frac{dV}{V} = nRT \left[ \ln V \right]_{V_i}^{V_f}. \quad (19-13)$$

By evaluating the expression in brackets at the limits and then using the relationship $\ln a - \ln b = \ln(a/b)$, we find that

$$W = nRT \ln \frac{V_f}{V_i} \quad (\text{ideal gas, isothermal process}). \quad (19-14)$$

Recall that the symbol $\ln$ specifies a natural logarithm, which has base $e$. 

[Figure 19-1](a) Before and (b) after images of a large steel tank crushed by atmospheric pressure after internal steam cooled and condensed.

[Figure 19-2] Three isotherms on a $p-V$ diagram. The path shown along the middle isotherm represents an isothermal expansion of a gas from an initial state $i$ to a final state $f$. The path from $f$ to $i$ along the isotherm would represent the reverse process—that is, an isothermal compression.
For an expansion, \( V_f \) is greater than \( V_i \), so the ratio \( V_f/V_i \) in Eq. 19-14 is greater than unity. The natural logarithm of a quantity greater than unity is positive, and so the work \( W \) done by an ideal gas during an isothermal expansion is positive, as we expect. For a compression, \( V_f \) is less than \( V_i \), so the ratio of volumes in Eq. 19-14 is less than unity. The natural logarithm in that equation—hence the work \( W \)—is negative, again as we expect.

**Work Done at Constant Volume and at Constant Pressure**

Equation 19-14 does not give the work \( W \) done by an ideal gas during *every* thermodynamic process. Instead, it gives the work only for a process in which the temperature is held constant. If the temperature varies, then the symbol \( T \) in Eq. 19-12 cannot be moved in front of the integral symbol as in Eq. 19-13, and thus we do not end up with Eq. 19-14.

However, we can always go back to Eq. 19-11 to find the work \( W \) done by an ideal gas (or any other gas) during any process, such as a constant-volume process and a constant-pressure process. If the volume of the gas is constant, then Eq. 19-11 yields

\[
W = 0 \quad \text{(constant-volume process).} \tag{19-15}
\]

If, instead, the volume changes while the pressure \( p \) of the gas is held constant, then Eq. 19-11 becomes

\[
W = p(V_f - V_i) = p \Delta V \quad \text{(constant-pressure process).} \tag{19-16}
\]

**Checkpoint 1**

An ideal gas has an initial pressure of 3 pressure units and an initial volume of 4 volume units. The table gives the final pressure and volume of the gas (in those same units) in five processes. Which processes start and end on the same isotherm?

**Sample Problem 19.01  Ideal gas and changes of temperature, volume, and pressure**

A cylinder contains 12 L of oxygen at 20°C and 15 atm. The temperature is raised to 35°C, and the volume is reduced to 8.5 L. What is the final pressure of the gas in atmospheres? Assume that the gas is ideal.

**KEY IDEA**

Because the gas is ideal, we can use the ideal gas law to relate its parameters, both in the initial state \( i \) and in the final state \( f \).

**Calculations:** From Eq. 19-5 we can write

\[
p_iV_i = nRT_i \quad \text{and} \quad p_fV_f = nRT_f.
\]

Dividing the second equation by the first equation and solving for \( p_f \) yields

\[
p_f = \frac{p_iT_iV_f}{T_fV_i}. \tag{19-17}
\]

Note here that if we converted the given initial and final volumes from liters to the proper units of cubic meters, the multiplying conversion factors would cancel out of Eq. 19-17. The same would be true for conversion factors that convert the pressures from atmospheres to the proper pascals. However, to convert the given temperatures to kelvins requires the addition of an amount that would not cancel and thus must be included. Hence, we must write

\[
T_i = (273 + 20) \text{ K} = 293 \text{ K}
\]
and

\[
T_f = (273 + 35) \text{ K} = 308 \text{ K}.
\]

Inserting the given data into Eq. 19-17 then yields

\[
p_f = \frac{(15 \text{ atm})(308 \text{ K})(12 \text{ L})}{(293 \text{ K})(8.5 \text{ L})} = 22 \text{ atm.} \tag{Answer}
\]
Sample Problem 19.02  Work by an ideal gas

One mole of oxygen (assume it to be an ideal gas) expands at a constant temperature $T$ of 310 K from an initial volume $V_i$ of 12 L to a final volume $V_f$ of 19 L. How much work is done by the gas during the expansion?

**KEY IDEA**

Generally we find the work by integrating the gas pressure with respect to the gas volume, using Eq. 19-11. However, because the gas here is ideal and the expansion is isothermal, that integration leads to Eq. 19-14.

**Calculation:** Therefore, we can write

$$W = nRT \ln \frac{V_f}{V_i}$$

$$= (1 \text{ mol})(8.31 \text{ J/mol} \cdot \text{K})(310 \text{ K}) \ln \frac{19 \text{ L}}{12 \text{ L}}$$

$$= 1180 \text{ J.}$$  (Answer)

The expansion is graphed in the $p$-$V$ diagram of Fig. 19-3. The work done by the gas during the expansion is represented by the area beneath the curve $if$.

You can show that if the expansion is now reversed, with the gas undergoing an isothermal compression from 19 L to 12 L, the work done by the gas will be $-1180$ J. Thus, an external force would have to do $1180$ J of work on the gas to compress it.

---

### 19-3 PRESSURE, TEMPERATURE, AND RMS SPEED

**Learning Objectives**

*After reading this module, you should be able to...*

19.14 Identify that the pressure on the interior walls of a gas container is due to the molecular collisions with the walls.

19.15 Relate the pressure on a container wall to the momentum of the gas molecules and the time intervals between their collisions with the wall.

19.16 For the molecules of an ideal gas, relate the root-mean-square speed $v_{\text{rms}}$ and the average speed $v_{\text{avg}}$.

19.17 Relate the pressure of an ideal gas to the rms speed $v_{\text{rms}}$ of the molecules.

19.18 For an ideal gas, apply the relationship between the gas temperature $T$ and the rms speed $v_{\text{rms}}$ and molar mass $M$ of the molecules.

**Key Ideas**

- In terms of the speed of the gas molecules, the pressure exerted by $n$ moles of an ideal gas is

$$p = \frac{nMv_{\text{rms}}^2}{3V},$$

where $v_{\text{rms}} = \sqrt{(v^2)_{\text{avg}}}$ is the root-mean-square speed of the molecules, $M$ is the molar mass, and $V$ is the volume.

- The rms speed can be written in terms of the temperature as

$$v_{\text{rms}} = \sqrt{\frac{3RT}{M}}.$$

**Pressure, Temperature, and RMS Speed**

Here is our first kinetic theory problem. Let $n$ moles of an ideal gas be confined in a cubical box of volume $V$, as in Fig. 19-4. The walls of the box are held at temperature $T$. What is the connection between the pressure $p$ exerted by the gas on the walls and the speeds of the molecules?
The molecules of gas in the box are moving in all directions and with various speeds, bumping into one another and bouncing from the walls of the box like balls in a racquetball court. We ignore (for the time being) collisions of the molecules with one another and consider only elastic collisions with the walls.

Figure 19-4 shows a typical gas molecule, of mass \( m \) and velocity \( \vec{v} \), that is about to collide with the shaded wall. Because we assume that any collision of a molecule with a wall is elastic, when this molecule collides with the shaded wall, the only component of its velocity that is changed is the \( x \) component, and that component is reversed. This means that the only change in the particle’s momentum is along the \( x \) axis, and that change is

\[
\Delta p_x = (-mv_x) - (mv_x) = -2mv_x.
\]

Hence, the momentum \( \Delta p_x \) delivered to the wall by the molecule during the collision is \(+2mv_x\). (Because in this book the symbol \( p \) represents both momentum and pressure, we must be careful to note that here \( p \) represents momentum and is a vector quantity.)

The molecule of Fig. 19-4 will hit the shaded wall repeatedly. The time \( \Delta t \) between collisions is the time the molecule takes to travel to the opposite wall and back again (a distance \( 2L \)) at speed \( v_x \). Thus, \( \Delta t \) is equal to \( 2L/v_x \). (Note that this result holds even if the molecule bounces off any of the other walls along the way, because those walls are parallel to \( x \) and so cannot change \( v_x \).) Therefore, the average rate at which momentum is delivered to the shaded wall by this single molecule is

\[
\frac{\Delta p_x}{\Delta t} = \frac{2mv_x}{2L/v_x} = \frac{mv_x^2}{L}.
\]

From Newton’s second law \( (\vec{F} = dp/dt) \), the rate at which momentum is delivered to the wall is the force acting on that wall. To find the total force, we must add up the contributions of all the molecules that strike the wall, allowing for the possibility that they all have different speeds. Dividing the magnitude of the total force \( F_x \) by the area of the wall \((= L^2)\) then gives the pressure \( p \) on that wall, where now and in the rest of this discussion, \( p \) represents pressure. Thus, using the expression for \( \Delta p_x/\Delta t \), we can write this pressure as

\[
p = \frac{F_x}{L^2} = \frac{mv_x^2/L + mv_{x2}^2/L + \cdots + mv_{xN}^2/L}{L^2}
= \left( \frac{m}{L^3} \right) (v_{x1}^2 + v_{x2}^2 + \cdots + v_{xN}^2),
\]

(19-18)

where \( N \) is the number of molecules in the box.

Since \( N = nN_A \), there are \( nN_A \) terms in the second set of parentheses of Eq. 19-18. We can replace that quantity by \( nN_A(v_x^2)_{\text{avg}} \), where \( (v_x^2)_{\text{avg}} \) is the average value of the square of the \( x \) components of all the molecular speeds. Equation 19-18 then becomes

\[
p = \frac{nmN_A}{L^3} (v_x^2)_{\text{avg}}.
\]

However, \( mN_A \) is the molar mass \( M \) of the gas (that is, the mass of 1 mol of the gas). Also, \( L^3 \) is the volume of the box, so

\[
p = \frac{nM(v_x^2)_{\text{avg}}}{V}.
\]

(19-19)

For any molecule, \( v^2 = v_x^2 + v_y^2 + v_z^2 \). Because there are many molecules and because they are all moving in random directions, the average values of the squares of their velocity components are equal, so that \( v_x^2 = \frac{1}{3} v^2 \). Thus, Eq. 19-19 becomes

\[
p = \frac{nM(v^2)_{\text{avg}}}{3V}.
\]

(19-20)
The square root of \((v^2)_{\text{avg}}\) is a kind of average speed, called the \textbf{root-mean-square speed} of the molecules and symbolized by \(v_{\text{rms}}\). Its name describes it rather well: You \textit{square} each speed, you find the \textit{mean} (that is, the average) of all these squared speeds, and then you take the square \textit{root} of that mean. With \(\sqrt{(v^2)_{\text{avg}}} = v_{\text{rms}}\), we can then write Eq. 19-20 as

\[
p = \frac{nMv_{\text{rms}}^2}{3V}.
\]  

(19-21)

This tells us how the pressure of the gas (a purely macroscopic quantity) depends on the speed of the molecules (a purely microscopic quantity).

We can turn Eq. 19-21 around and use it to calculate \(v_{\text{rms}}\). Combining Eq. 19-21 with the ideal gas law \((pV = nRT)\) leads to

\[
v_{\text{rms}} = \sqrt{\frac{3RT}{M}}.
\]  

(19-22)

Table 19-1 shows some rms speeds calculated from Eq. 19-22. The speeds are surprisingly high. For hydrogen molecules at room temperature (300 K), the rms speed is 1920 m/s, or 4300 mi/h—faster than a speeding bullet! On the surface of the Sun, where the temperature is \(2 \times 10^6\) K, the rms speed of hydrogen molecules would be 82 times greater than at room temperature were it not for the fact that at such high speeds, the molecules cannot survive collisions among themselves. Remember too that the rms speed is only a kind of average speed; many molecules move much faster than this, and some much slower.

The speed of sound in a gas is closely related to the rms speed of the molecules of that gas. In a sound wave, the disturbance is passed on from molecule to molecule by means of collisions. The wave cannot move any faster than the “average” speed of the molecules. In fact, the speed of sound must be somewhat less than this “average” molecular speed because not all molecules are moving in exactly the same direction as the wave. As examples, at room temperature, the rms speeds of hydrogen and nitrogen molecules are 1920 m/s and 517 m/s, respectively. The speeds of sound in these two gases at this temperature are 1350 m/s and 350 m/s, respectively.

A question often arises: If molecules move so fast, why does it take as long as a minute or so before you can smell perfume when someone opens a bottle across a room? The answer is that, as we shall discuss in Module 19-5, each perfume molecule may have a high speed but it moves away from the bottle only very slowly because its repeated collisions with other molecules prevent it from moving directly across the room to you.

*For convenience, we often set room temperature equal to 300 K even though (at 27°C or 81°F) that represents a fairly warm room.*

**Sample Problem 19.03** Average and rms values

Here are five numbers: 5, 11, 32, 67, and 89.

(a) What is the average value \(n_{\text{avg}}\) of these numbers?

**Calculation:** We find this from

\[
n_{\text{avg}} = \frac{5 + 11 + 32 + 67 + 89}{5} = 40.8.
\]

(Answer)

(b) What is the rms value \(n_{\text{rms}}\) of these numbers?

**Calculation:** We find this from

\[
n_{\text{rms}} = \sqrt{\frac{5^2 + 11^2 + 32^2 + 67^2 + 89^2}{5}} = 52.1.
\]

19-4 TRANSLATIONAL KINETIC ENERGY

Learning Objectives

After reading this module, you should be able to . . .

19.19 For an ideal gas, relate the average kinetic energy of the molecules to their rms speed.
19.20 Apply the relationship between the average kinetic energy and the temperature of the gas.
19.21 Identify that a measurement of a gas temperature is effectively a measurement of the average kinetic energy of the gas molecules.

Key Ideas

- The average translational kinetic energy per molecule in an ideal gas is

\[ K_{\text{avg}} = \frac{1}{2} m v_{\text{rms}}^2. \]

- The average translational kinetic energy is related to the temperature of the gas:

\[ K_{\text{avg}} = \frac{3}{2} kT. \]

Translational Kinetic Energy

We again consider a single molecule of an ideal gas as it moves around in the box of Fig. 19-4, but we now assume that its speed changes when it collides with other molecules. Its translational kinetic energy at any instant is \( \frac{1}{2} m v^2 \). Its average translational kinetic energy over the time that we watch it is

\[ K_{\text{avg}} = \frac{1}{2} m (v^2)_{\text{avg}} = \frac{1}{2} m v_{\text{rms}}^2, \]

in which we make the assumption that the average speed of the molecule during our observation is the same as the average speed of all the molecules at any given time. (Provided the total energy of the gas is not changing and provided we observe our molecule for long enough, this assumption is appropriate.) Substituting for \( v_{\text{rms}} \) from Eq. 19-22 leads to

\[ K_{\text{avg}} = \frac{1}{2} m \frac{3RT}{M}. \]

However, \( M/m \), the molar mass divided by the mass of a molecule, is simply Avogadro’s number. Thus,

\[ K_{\text{avg}} = \frac{3RT}{2N_A}. \]

Using Eq. 19-7 \( (k = R/N_A) \), we can then write

\[ K_{\text{avg}} = \frac{3}{2} kT. \] (19-24)

This equation tells us something unexpected:

At a given temperature \( T \), all ideal gas molecules—no matter what their mass—have the same average translational kinetic energy—namely, \( \frac{3}{2} kT \). When we measure the temperature of a gas, we are also measuring the average translational kinetic energy of its molecules.

Checkpoint 2

A gas mixture consists of molecules of types 1, 2, and 3, with molecular masses \( m_1 > m_2 > m_3 \). Rank the three types according to (a) average kinetic energy and (b) rms speed, greatest first.
We continue to examine the motion of molecules in an ideal gas. Figure 19-5 shows the path of a typical molecule as it moves through the gas, changing both speed and direction abruptly as it collides elastically with other molecules. Between collisions, the molecule moves in a straight line at constant speed. Although the figure shows the other molecules as stationary, they are (of course) also moving.

One useful parameter to describe this random motion is the mean free path \( \lambda \) of the molecules. As its name implies, \( \lambda \) is the average distance traversed by a molecule between collisions. We expect \( \lambda \) to vary inversely with \( N/V \), the number of molecules per unit volume (or density of molecules). The larger \( N/V \) is, the more collisions there should be and the smaller the mean free path. We also expect \( \lambda \) to vary inversely with the size of the molecules — with their diameter \( d \), say. (If the molecules were points, as we have assumed them to be, they would never collide and the mean free path would be infinite.) Thus, the larger the molecules are, the smaller the mean free path. We can even predict that \( \lambda \) should vary (inversely) as the square of the molecular diameter because the cross section of a molecule — not its diameter — determines its effective target area.

The expression for the mean free path does, in fact, turn out to be

\[
\lambda = \frac{1}{\sqrt{2} \pi d^2 N/V},
\]

where \( N/V \) is the number of molecules per unit volume and \( d \) is the molecular diameter.

**Mean Free Path**

We continue to examine the motion of molecules in an ideal gas. Figure 19-5 shows the path of a typical molecule as it moves through the gas, changing both speed and direction abruptly as it collides elastically with other molecules. Between collisions, the molecule moves in a straight line at constant speed. Although the figure shows the other molecules as stationary, they are (of course) also moving.

One useful parameter to describe this random motion is the mean free path \( \lambda \) of the molecules. As its name implies, \( \lambda \) is the average distance traversed by a molecule between collisions. We expect \( \lambda \) to vary inversely with \( N/V \), the number of molecules per unit volume (or density of molecules). The larger \( N/V \) is, the more collisions there should be and the smaller the mean free path. We also expect \( \lambda \) to vary inversely with the size of the molecules — with their diameter \( d \), say. (If the molecules were points, as we have assumed them to be, they would never collide and the mean free path would be infinite.) Thus, the larger the molecules are, the smaller the mean free path. We can even predict that \( \lambda \) should vary (inversely) as the square of the molecular diameter because the cross section of a molecule — not its diameter — determines its effective target area.

The expression for the mean free path does, in fact, turn out to be

\[
\lambda = \frac{1}{\sqrt{2} \pi d^2 N/V}, 
\]

(mean free path).

To justify Eq. 19-25, we focus attention on a single molecule and assume — as Fig. 19-5 suggests — that our molecule is traveling with a constant speed \( v \) and that all the other molecules are at rest. Later, we shall relax this assumption.

We assume further that the molecules are spheres of diameter \( d \). A collision will then take place if the centers of two molecules come within a distance \( d \) of each other, as in Fig. 19-6a. Another, more helpful way to look at the situation is
to consider our single molecule to have a radius of \( d \) and all the other molecules to be points, as in Fig. 19-6b. This does not change our criterion for a collision.

As our single molecule zigzags through the gas, it sweeps out a short cylinder of cross-sectional area \( \pi d^2 \) between successive collisions. If we watch this molecule for a time interval \( \Delta t \), it moves a distance \( v \Delta t \), where \( v \) is its assumed speed. Thus, if we align all the short cylinders swept out in interval \( \Delta t \), we form a composite cylinder (Fig. 19-7) of length \( v \Delta t \) and volume \( (\pi d^2)(v \Delta t) \). The number of collisions that occur in time \( \Delta t \) is then equal to the number of (point) molecules that lie within this cylinder.

Since \( N/V \) is the number of molecules per unit volume, the number of molecules in the cylinder is \( N/V \) times the volume of the cylinder, or \( (N/V)(\pi d^2 v \Delta t) \). This is also the number of collisions in time \( \Delta t \). The mean free path is the length of the path (and of the cylinder) divided by this number:

\[
\lambda = \frac{\text{length of path during } \Delta t}{\text{number of collisions in } \Delta t} = \frac{v \Delta t}{\pi d^2 v \Delta t N/V} \]

\[
= \frac{1}{\pi d^2 N/V}. \tag{19-26}
\]

This equation is only approximate because it is based on the assumption that all the molecules except one are at rest. In fact, all the molecules are moving; when this is taken properly into account, Eq. 19-25 results. Note that it differs from the (approximate) Eq. 19-26 only by a factor of \( 1/\sqrt{2} \).

The approximation in Eq. 19-26 involves the two \( v \) symbols we canceled. The \( v \) in the numerator is \( v_{\text{avg}} \), the mean speed of the molecules relative to the container. The \( v \) in the denominator is \( v_{\text{rel}} \), the mean speed of our single molecule relative to the other molecules, which are moving. It is this latter average speed that determines the number of collisions. A detailed calculation, taking into account the actual speed distribution of the molecules, gives \( v_{\text{rel}} = \sqrt{2} v_{\text{avg}} \) and thus the factor \( \sqrt{2} \).

The mean free path of air molecules at sea level is about 0.1 \( \mu m \). At an altitude of 100 km, the density of air has dropped to such an extent that the mean free path rises to about 16 cm. At 300 km, the mean free path is about 20 km. A problem faced by those who would study the physics and chemistry of the upper atmosphere in the laboratory is the unavailability of containers large enough to hold gas samples (of Freon, carbon dioxide, and ozone) that simulate upper atmospheric conditions.

**Checkpoint 3**

One mole of gas \( A \), with molecular diameter \( 2d_0 \) and average molecular speed \( v_0 \), is placed inside a certain container. One mole of gas \( B \), with molecular diameter \( d_0 \) and average molecular speed \( 2v_0 \) (the molecules of \( B \) are smaller but faster), is placed in an identical container. Which gas has the greater average collision rate within its container?
Sample Problem 19.04  Mean free path, average speed, collision frequency

(a) What is the mean free path \( \lambda \) for oxygen molecules at temperature \( T = 300 \text{ K} \) and pressure \( p = 1.0 \text{ atm} \)? Assume that the molecular diameter is \( d = 290 \text{ pm} \) and the gas is ideal.

**KEY IDEA**

Each oxygen molecule moves among other moving oxygen molecules in a zigzag path due to the resulting collisions. Thus, we use Eq. 19-25 for the mean free path.

**Calculation:** We first need the number of molecules per unit volume, \( N/V \). Because we assume the gas is ideal, we can use the ideal gas law of Eq. 19-9 \((pV = NkT)\) to write \( N/V = p/kT \). Substituting this into Eq. 19-25, we find

\[
\lambda = \frac{1}{\sqrt{2 \pi d^2} \frac{N}{V}} = \frac{kT}{\sqrt{2 \pi d^2} p} = \frac{1}{\sqrt{2 \pi d^2} p} \left( \frac{1.38 \times 10^{-23} \text{ J/K}}{300 \text{ K}} \right) \left( 2.9 \times 10^{-10} \text{ m}^2 \right) \left( 1.01 \times 10^5 \text{ Pa} \right)
\]

\[
= 1.1 \times 10^{-7} \text{ m.} \quad \text{(Answer)}
\]

This is about 380 molecular diameters.

(b) Assume the average speed of the oxygen molecules is \( v = 450 \text{ m/s} \). What is the average time \( t \) between successive collisions for any given molecule? At what rate does the molecule collide; that is, what is the frequency \( f \) of its collisions?

**KEY IDEAS**

(1) Between collisions, the molecule travels, on average, the mean free path \( \lambda \) at speed \( v \). (2) The average rate or frequency at which the collisions occur is the inverse of the time \( t \) between collisions.

**Calculations:** From the first key idea, the average time between collisions is

\[
t = \frac{\text{distance}}{\text{speed}} = \frac{\lambda}{v} = \frac{1.1 \times 10^{-7} \text{ m}}{450 \text{ m/s}}
\]

\[
= 2.44 \times 10^{-10} \text{ s} = 0.24 \text{ ns.} \quad \text{(Answer)}
\]

This tells us that, on average, any given oxygen molecule has less than a nanosecond between collisions.

From the second key idea, the collision frequency is

\[
f = \frac{1}{t} = \frac{1}{2.44 \times 10^{-10} \text{ s}} = 4.1 \times 10^9 \text{ s}^{-1}. \quad \text{(Answer)}
\]

This tells us that, on average, any given oxygen molecule makes about 4 billion collisions per second.

19-6 THE DISTRIBUTION OF MOLECULAR SPEEDS

**Learning Objectives**

After reading this module, you should be able to . . .

19.24 Explain how Maxwell’s speed distribution law is used to find the fraction of molecules with speeds in a certain speed range.

19.25 Sketch a graph of Maxwell’s speed distribution, showing the probability distribution versus speed and indicating the relative positions of the average speed \( v_{\text{avg}} \), the most probable speed \( v_p \), and the rms speed \( v_{\text{rms}} \).

19.26 Explain how Maxwell’s speed distribution is used to find the average speed, the rms speed, and the most probable speed.

19.27 For a given temperature \( T \) and molar mass \( M \), calculate the average speed \( v_{\text{avg}} \), the most probable speed \( v_p \), and the rms speed \( v_{\text{rms}} \).

**Key Ideas**

- The Maxwell speed distribution \( P(v) \) is a function such that \( P(v) \, dv \) gives the fraction of molecules with speeds in the interval \( dv \) at speed \( v \):

\[
P(v) = 4\pi \left( \frac{M}{2\pi RT} \right)^{3/2} v^2 e^{-Mv^2/2RT}.
\]

- Three measures of the distribution of speeds among the molecules of a gas are

\[
v_{\text{avg}} = \sqrt{\frac{8RT}{\pi M}} \quad \text{(average speed)},
\]

\[
v_p = \sqrt{\frac{2RT}{M}} \quad \text{(most probable speed)},
\]

and

\[
v_{\text{rms}} = \sqrt{\frac{3RT}{M}} \quad \text{(rms speed)}.
\]
The Distribution of Molecular Speeds

The root-mean-square speed \( v_{\text{rms}} \) gives us a general idea of molecular speeds in a gas at a given temperature. We often want to know more. For example, what fraction of the molecules have speeds greater than the rms value? What fraction have speeds greater than twice the rms value? To answer such questions, we need to know how the possible values of speed are distributed among the molecules. Figure 19-8a shows this distribution for oxygen molecules at room temperature \((T = 300 \text{ K})\); Fig. 19-8b compares it with the distribution at \( T = 80 \text{ K} \).

In 1852, Scottish physicist James Clerk Maxwell first solved the problem of finding the speed distribution of gas molecules. His result, known as Maxwell's speed distribution law, is

\[
P(v) = 4\pi \left( \frac{M}{2\pi RT} \right)^{3/2} v^2 e^{-Mv^2/2RT}. \tag{19-27}
\]

Here \( M \) is the molar mass of the gas, \( R \) is the gas constant, \( T \) is the gas temperature, and \( v \) is the molecular speed. It is this equation that is plotted in Fig. 19-8a, b. The quantity \( P(v) \) in Eq. 19-27 and Fig. 19-8 is a probability distribution function: For any speed \( v \), the product \( P(v) \, dv \) (a dimensionless quantity) is the fraction of molecules with speeds in the interval \( dv \) centered on speed \( v \).

As Fig. 19-8a shows, this fraction is equal to the area of a strip with height \( P(v) \) and width \( dv \). The total area under the distribution curve corresponds to the fraction of the molecules whose speeds lie between zero and infinity. All molecules fall into this category, so the value of this total area is unity; that is,

\[
\int_0^\infty P(v) \, dv = 1. \tag{19-28}
\]

The fraction (frac) of molecules with speeds in an interval of, say, \( v_1 \) to \( v_2 \) is then

\[
\text{frac} = \int_{v_1}^{v_2} P(v) \, dv. \tag{19-29}
\]

Average, RMS, and Most Probable Speeds

In principle, we can find the average speed \( v_{\text{avg}} \) of the molecules in a gas with the following procedure: We weight each value of \( v \) in the distribution; that is, we multiply it...
by the fraction \( P(v) \, dv \) of molecules with speeds in a differential interval \( dv \) centered on \( v \). Then we add up all these values of \( v \, P(v) \, dv \). The result is \( v_{\text{avg}} \). In practice, we do all this by evaluating
\[
v_{\text{avg}} = \int_{0}^{\infty} v \, P(v) \, dv.
\] (19-30)

Substituting for \( P(v) \) from Eq. 19-27 and using generic integral 20 from the list of integrals in Appendix E, we find
\[
v_{\text{avg}} = \sqrt{\frac{8RT}{\pi M}} \quad \text{(average speed).}
\] (19-31)

Similarly, we can find the average of the square of the speeds \((v^2)_{\text{avg}}\) with
\[
(v^2)_{\text{avg}} = \int_{0}^{\infty} v^2 \, P(v) \, dv.
\] (19-32)

Substituting for \( P(v) \) from Eq. 19-27 and using generic integral 16 from the list of integrals in Appendix E, we find
\[
(v^2)_{\text{avg}} = \frac{3RT}{M}.
\] (19-33)

The square root of \((v^2)_{\text{avg}}\) is the root-mean-square speed \( v_{\text{rms}} \). Thus,
\[
v_{\text{rms}} = \sqrt{\frac{3RT}{M}} \quad \text{(rms speed).}
\] (19-34)

which agrees with Eq. 19-22.

The **most probable speed** \( v_p \) is the speed at which \( P(v) \) is maximum (see Fig. 19-8a). To calculate \( v_p \), we set \( dP/dv = 0 \) (the slope of the curve in Fig. 19-8a is zero at the maximum of the curve) and then solve for \( v \). Doing so, we find
\[
v_p = \sqrt{\frac{2RT}{M}} \quad \text{(most probable speed).}
\] (19-35)

A molecule is more likely to have speed \( v_p \) than any other speed, but some molecules will have speeds that are many times \( v_p \). These molecules lie in the **high-speed tail** of a distribution curve like that in Fig. 19-8a. Such higher speed molecules make possible both rain and sunshine (without which we could not exist):

**Rain** The speed distribution of water molecules in, say, a pond at summertime temperatures can be represented by a curve similar to that of Fig. 19-8a. Most of the molecules lack the energy to escape from the surface. However, a few of the molecules in the high-speed tail of the curve can do so. It is these water molecules that evaporate, making clouds and rain possible.

As the fast water molecules leave the surface, carrying energy with them, the temperature of the remaining water is maintained by heat transfer from the surroundings. Other fast molecules—produced in particularly favorable collisions—quickly take the place of those that have left, and the speed distribution is maintained.

**Sunshine** Let the distribution function of Eq. 19-27 now refer to protons in the core of the Sun. The Sun’s energy is supplied by a nuclear fusion process that starts with the merging of two protons. However, protons repel each other because of their electrical charges, and protons of average speed do not have enough kinetic energy to overcome the repulsion and get close enough to merge. Very fast protons with speeds in the high-speed tail of the distribution curve can do so, however, and for that reason the Sun can shine.
Sample Problem 19.05  Speed distribution in a gas

In oxygen (molar mass \( M = 0.0320 \text{ kg/mol} \)) at room temperature (300 K), what fraction of the molecules have speeds in the interval 599 to 601 m/s?

**KEY IDEAS**

1. The speeds of the molecules are distributed over a wide range of values, with the distribution \( P(v) \) of Eq. 19-27.
2. The fraction of molecules with speeds in a differential interval \( dv \) is \( P(v) \) \( dv \).
3. For a larger interval, the fraction is found by integrating \( P(v) \) over the interval.
4. However, the interval \( \Delta v = 2 \text{ m/s} \) here is small compared to the speed \( v = 600 \text{ m/s} \) on which it is centered.

**Calculations:** Because \( \Delta v \) is small, we can avoid the integration by approximating the fraction as

\[
\text{frac} = P(v) \Delta v = 4\pi \left( \frac{M}{2\pi RT} \right)^{3/2} v^2 e^{-Mv^2/2RT} \Delta v.
\]

Sample Problem 19.06  Average speed, rms speed, most probable speed

The molar mass \( M \) of oxygen is 0.0320 kg/mol.

(a) What is the average speed \( v_{\text{avg}} \) of oxygen gas molecules at \( T = 300 \text{ K} \)?

**KEY IDEA**

To find the average speed, we must weight speed \( v \) with the distribution function \( P(v) \) of Eq. 19-27 and then integrate the resulting expression over the range of possible speeds (from zero to the limit of an infinite speed).

**Calculation:** We end up with Eq. 19-31, which gives us

\[
v_{\text{avg}} = \sqrt{\frac{8RT}{\pi M}} = \sqrt{\frac{8(8.31 \text{ J/mol} \cdot \text{K})(300 \text{ K})}{\pi(0.0320 \text{ kg/mol})}} = 445 \text{ m/s}.
\]

This result is plotted in Fig. 19-8a.

(b) What is the root-mean-square speed \( v_{\text{rms}} \) at 300 K?

**KEY IDEA**

To find \( v_{\text{rms}} \), we must first find \((v^2)_{\text{avg}}\) by weighting \( v^2 \) with the distribution function \( P(v) \) of Eq. 19-27 and then integrating the expression over the range of possible speeds. Then we must take the square root of the result.

\[
v_{\text{rms}} = \sqrt{\frac{2RT}{M}} = \sqrt{\frac{2(8.31 \text{ J/mol} \cdot \text{K})(300 \text{ K})}{0.0320 \text{ kg/mol}}} = 395 \text{ m/s}.
\]

This result is also plotted in Fig. 19-8a.
The Molar Specific Heats of an Ideal Gas

Learning Objectives

After reading this module, you should be able to . . .

19.28 Identify that the internal energy of an ideal monatomic gas is the sum of the translational kinetic energies of its atoms.
19.29 Apply the relationship between the internal energy $E_{\text{int}}$ of a monatomic ideal gas, the number of moles $n$, and the gas temperature $T$.
19.30 Distinguish between monatomic, diatomic, and polyatomic ideal gases.
19.31 For monatomic, diatomic, and polyatomic ideal gases, evaluate the molar specific heats for a constant-volume process and a constant-pressure process.
19.32 Calculate a molar specific heat at constant pressure $C_p$ by adding $R$ to the molar specific heat at constant volume $C_V$, and explain why (physically) $C_p$ is greater.
19.33 Identify that the energy transferred to an ideal gas as heat in a constant-volume process goes entirely into the internal energy (the random translational motion) but that in a constant-pressure process energy also goes into the work done to expand the gas.
19.34 Identify that for a given change in temperature, the change in the internal energy of an ideal gas is the same for any process and is most easily calculated by assuming a constant-volume process.
19.35 For an ideal gas, apply the relationship between heat $Q$, number of moles $n$, and temperature change $\Delta T$, using the appropriate molar specific heat.
19.36 Between two isotherms on a $p$-$V$ diagram, sketch a constant-volume process and a constant-pressure process, and for each identify the work done in terms of area on the graph.
19.37 Calculate the work done by an ideal gas for a constant-pressure process.
19.38 Identify that work is zero for constant volume.

Key Ideas

- The molar specific heat $C_V$ of a gas at constant volume is defined as
  $$C_V = \frac{Q}{n \Delta T} = \frac{\Delta E_{\text{int}}}{n \Delta T},$$
  in which $Q$ is the energy transferred as heat to or from a sample of $n$ moles of the gas, $\Delta T$ is the resulting temperature change of the gas, and $\Delta E_{\text{int}}$ is the resulting change in the internal energy of the gas.
- For an ideal monatomic gas,
  $$C_V = \frac{3}{2}R = 12.5 \text{ J/mol} \cdot \text{K}.$$
- The molar specific heat $C_p$ of a gas at constant pressure is defined to be
  $$C_p = \frac{Q}{n \Delta T},$$
  in which $Q$, $n$, and $\Delta T$ are defined as above. $C_p$ is also given by
  $$C_p = C_V + R.$$
- For $n$ moles of an ideal gas,
  $$E_{\text{int}} = nC_V T \quad (\text{ideal gas}).$$
- If $n$ moles of a confined ideal gas undergo a temperature change $\Delta T$ due to any process, the change in the internal energy of the gas is
  $$\Delta E_{\text{int}} = nC_V \Delta T \quad (\text{ideal gas, any process}).$$

The Molar Specific Heats of an Ideal Gas

In this module, we want to derive from molecular considerations an expression for the internal energy $E_{\text{int}}$ of an ideal gas. In other words, we want an expression for the energy associated with the random motions of the atoms or molecules in the gas. We shall then use that expression to derive the molar specific heats of an ideal gas.

Internal Energy $E_{\text{int}}$

Let us first assume that our ideal gas is a monatomic gas (individual atoms rather than molecules), such as helium, neon, or argon. Let us also assume that the internal energy $E_{\text{int}}$ is the sum of the translational kinetic energies of the atoms. (Quantum theory disallows rotational kinetic energy for individual atoms.)

The average translational kinetic energy of a single atom depends only on the gas temperature and is given by Eq. 19-24 as $K_{\text{avg}} = \frac{1}{2}kT$. A sample of $n$ moles of such a gas contains $nN_A$ atoms. The internal energy $E_{\text{int}}$ of the sample is then

$$E_{\text{int}} = (nN_A)K_{\text{avg}} = (nN_A)(\frac{1}{2}kT). \quad (19-37)$$
Using Eq. 19-7 \((k = R/N_A)\), we can rewrite this as

\[
E_{\text{int}} = \frac{1}{2}nRT \quad \text{(monatomic ideal gas).} \tag{19-38}
\]

The internal energy \(E_{\text{int}}\) of an ideal gas is a function of the gas temperature only; it does not depend on any other variable.

With Eq. 19-38 in hand, we are now able to derive an expression for the molar specific heat of an ideal gas. Actually, we shall derive two expressions. One is for the case in which the volume of the gas remains constant as energy is transferred to or from it as heat. The other is for the case in which the pressure of the gas remains constant as energy is transferred to or from it as heat. The symbols for these two molar specific heats are \(C_V\) and \(C_p\), respectively. (By convention, the capital letter \(C\) is used in both cases, even though \(C_V\) and \(C_p\) represent types of specific heat and not heat capacities.)

**Molar Specific Heat at Constant Volume**

Figure 19-9a shows \(n\) moles of an ideal gas at pressure \(p\) and temperature \(T\), confined to a cylinder of fixed volume \(V\). This initial state \(i\) of the gas is marked on the \(p-V\) diagram of Fig. 19-9b. Suppose now that you add a small amount of energy to the gas as heat \(Q\) by slowly turning up the temperature of the thermal reservoir. The gas temperature rises a small amount to \(T + \Delta T\), and its pressure rises to \(p + \Delta p\), bringing the gas to final state \(f\). In such experiments, we would find that the heat \(Q\) is related to the temperature change \(\Delta T\) by

\[
Q = nC_V \Delta T \quad \text{(constant volume),} \tag{19-39}
\]

where \(C_V\) is a constant called the molar specific heat at constant volume. Substituting this expression for \(Q\) into the first law of thermodynamics as given by Eq. 18-26 \((\Delta E_{\text{int}} = Q - W)\) yields

\[
\Delta E_{\text{int}} = nC_V \Delta T - W. \tag{19-40}
\]

With the volume held constant, the gas cannot expand and thus cannot do any work. Therefore, \(W = 0\), and Eq. 19-40 gives us

\[
C_V = \frac{\Delta E_{\text{int}}}{n \Delta T}. \tag{19-41}
\]

From Eq. 19-38, the change in internal energy must be

\[
\Delta E_{\text{int}} = \frac{1}{2}nR \Delta T. \tag{19-42}
\]

Substituting this result into Eq. 19-41 yields

\[
C_V = \frac{1}{2}R = 12.5 \text{ J/mol} \cdot \text{K} \quad \text{(monatomic gas).} \tag{19-43}
\]

As Table 19-2 shows, this prediction of the kinetic theory (for ideal gases) agrees very well with experiment for real monatomic gases, the case that we have assumed. The (predicted and) experimental values of \(C_V\) for diatomic gases (which have molecules with two atoms) and polyatomic gases (which have molecules with more than two atoms) are greater than those for monatomic gases for reasons that will be suggested in Module 19-8. Here we make the preliminary assumption that the \(C_V\) values for diatomic and polyatomic gases are greater than for monatomic gases because the more complex molecules can rotate and thus have rotational kinetic energy. So, when \(Q\) is transferred to a diatomic or polyatomic gas, only part of it goes into the translational kinetic energy, increasing the

temperature. (For now we neglect the possibility of also putting energy into oscillations of the molecules.)

We can now generalize Eq. 19-38 for the internal energy of any ideal gas by substituting $C_v$ for $\frac{1}{2}R$; we get

$$E_{\text{int}} = nC_vT \quad \text{(any ideal gas).} \quad (19-44)$$

This equation applies not only to an ideal monatomic gas but also to diatomic and polyatomic ideal gases, provided the appropriate value of $C_v$ is used. Just as with Eq. 19-38, we see that the internal energy of a gas depends on the temperature of the gas but not on its pressure or density.

When a confined ideal gas undergoes temperature change $\Delta T$, then from either Eq. 19-41 or Eq. 19-44 the resulting change in its internal energy is

$$\Delta E_{\text{int}} = nC_v \Delta T \quad \text{(ideal gas, any process).} \quad (19-45)$$

This equation tells us:

A change in the internal energy $E_{\text{int}}$ of a confined ideal gas depends on only the change in the temperature, not on what type of process produces the change.

As examples, consider the three paths between the two isotherms in the $p$-$V$ diagram of Fig. 19-10. Path 1 represents a constant-volume process. Path 2 represents a constant-pressure process (we examine it next). Path 3 represents a process in which no heat is exchanged with the system’s environment (we discuss this in Module 19-9). Although the values of heat $Q$ and work $W$ associated with these three paths differ, as do $p_i$ and $V_i$, the values of $\Delta E_{\text{int}}$ associated with the three paths are identical and are all given by Eq. 19-45, because they all involve the same temperature change $\Delta T$. Therefore, no matter what path is actually taken between $T$ and $T + \Delta T$, we can always use path 1 and Eq. 19-45 to compute $\Delta E_{\text{int}}$ easily.

Molar Specific Heat at Constant Pressure

We now assume that the temperature of our ideal gas is increased by the same small amount $\Delta T$ as previously but now the necessary energy (heat $Q$) is added with the gas under constant pressure. An experiment for doing this is shown in Fig. 19-11a; the $p$-$V$ diagram for the process is plotted in Fig. 19-11b. From such experiments we find that the heat $Q$ is related to the temperature change $\Delta T$ by

$$Q = nC_p \Delta T \quad \text{(constant pressure),} \quad (19-46)$$

where $C_p$ is a constant called the molar specific heat at constant pressure. This $C_p$ is greater than the molar specific heat at constant volume $C_v$ because energy must now be supplied not only to raise the temperature of the gas but also for the gas to do work — that is, to lift the weighted piston of Fig. 19-11a.

To relate molar specific heats $C_p$ and $C_v$, we start with the first law of thermodynamics (Eq. 18-26):

$$\Delta E_{\text{int}} = Q - W. \quad (19-47)$$

We next replace each term in Eq. 19-47. For $\Delta E_{\text{int}}$, we substitute from Eq. 19-45. For $Q$, we substitute from Eq. 19-46. To replace $W$, we first note that since the pressure remains constant, Eq. 19-16 tells us that $W = p \Delta V$. Then we note that, using the ideal gas equation ($pV = nRT$), we can write

$$W = p \Delta V = nR \Delta T. \quad (19-48)$$

Making these substitutions in Eq. 19-47 and then dividing through by $n \Delta T$, we find

$$C_v = C_p - R$$
and then

$$C_p = C_V + R. \quad (19-49)$$

This prediction of kinetic theory agrees well with experiment, not only for monatomic gases but also for gases in general, as long as their density is low enough so that we may treat them as ideal.

The left side of Fig. 19-12 shows the relative values of $Q$ for a monatomic gas undergoing either a constant-volume process (labeled “con V”) and a constant-pressure process (labeled “con $p$”). The transfer of the energy into work $W$ and internal energy ($\Delta E_{\text{int}}$) is noted.

Checkpoint 4

The figure here shows five paths traversed by a gas on a $p$-$V$ diagram. Rank the paths according to the change in internal energy of the gas, greatest first.

Sample Problem 19.07  Monatomic gas, heat, internal energy, and work

A bubble of 5.00 mol of helium is submerged at a certain depth in liquid water when the water (and thus the helium) undergoes a temperature increase $\Delta T$ of 20.0°C at constant pressure. As a result, the bubble expands. The helium is monatomic and ideal.

(a) How much energy is added to the helium as heat during the increase and expansion?

**KEY IDEA**

Heat $Q$ is related to the temperature change $\Delta T$ by a molar specific heat of the gas.

**Calculations:** Because the pressure $p$ is held constant during the addition of energy, we use the molar specific heat at constant pressure $C_p$ and Eq. 19-46,

$$Q = nC_p \Delta T, \quad (19-50)$$

to find $Q$. To evaluate $C_p$ we go to Eq. 19-49, which tells us that for any ideal gas, $C_p = C_V + R$. Then from Eq. 19-43, we know that for any monatomic gas (like the helium here), $C_V = \frac{3}{2}R$. Thus, Eq. 19-50 gives us

$$Q = n(C_V + R) \Delta T = n\left(\frac{3}{2}R + R\right) \Delta T = n\left(\frac{5}{2}R\right) \Delta T$$

$$= (5.00 \, \text{mol})(2.5) \times (8.31 \, \text{J/mol-K})(20.0 \, \text{C}^\circ)$$

$$= 2077.5 \, \text{J} = 2080 \, \text{J}. \quad \textbf{(Answer)}$$

(b) What is the change $\Delta E_{\text{int}}$ in the internal energy of the helium during the temperature increase?
As Table 19-2 shows, the prediction that $C_V = \frac{3}{2}R$ agrees with experiment for monatomic gases but fails for diatomic and polyatomic gases. Let us try to explain the discrepancy by considering the possibility that molecules with more than one atom can store internal energy in forms other than translational kinetic energy.

Figure 19-13 shows common models of helium (a monatomic molecule, containing a single atom), oxygen (a diatomic molecule, containing two atoms), and...
Every kind of molecule has a certain number of degrees of freedom, which are independent ways in which the molecule can store energy. Each such degree of freedom has associated with it — on average — an energy of 1/2 kT per molecule (or per mole).

Let us apply the theorem to the translational and rotational motions of the molecules in Fig. 19-13. (We discuss oscillatory motion below.) For the translational motion, superimpose an xyz coordinate system on any gas. The molecules will, in general, have velocity components along all three axes. Thus, gas molecules of all types have three degrees of translational freedom (three ways to move in translation) and, on average, an associated energy of 1/2 kT per molecule.

For the rotational motion, imagine the origin of our xyz coordinate system at the center of each molecule in Fig. 19-13. In a gas, each molecule should be able to rotate with an angular velocity component along each of the three axes, so each gas molecule should have three degrees of rotational freedom and, on average, an additional energy of 1/2 kT per molecule. However, experiment shows this is true only for the polyatomic molecules. According to quantum theory, the physics dealing with the allowed motions and energies of molecules and atoms, a monatomic gas molecule does not rotate and so has no rotational energy (a single atom cannot rotate like a top). A diatomic molecule can rotate like a top only about axes perpendicular to the line connecting the atoms (the axes are shown in Fig. 19-13b) and not about that line itself. Therefore, a diatomic molecule can have only two degrees of rotational freedom and a rotational energy of only 1/2 kT per molecule.

To extend our analysis of molar specific heats (C_p and C_v in Module 19-7) to ideal diatomic and polyatomic gases, it is necessary to retrace the derivations of that analysis in detail. First, we replace Eq. 19-38 (E_int = 1/2 nRT) with E_int = (f/2)nRT, where f is the number of degrees of freedom listed in Table 19-3. Doing so leads to the prediction

\[ C_v = \left( \frac{f}{2} \right) R = 4.16f \text{ J/mol} \cdot \text{K}, \]  

(19-51)

which agrees — as it must — with Eq. 19-43 for monatomic gases (f = 3). As Table 19-2 shows, this prediction also agrees with experiment for diatomic gases (f = 5), but it is too low for polyatomic gases (f = 6 for molecules comparable to CH_4).

**Sample Problem 19.08 Diatomic gas, heat, temperature, internal energy**

We transfer 1000 J as heat Q to a diatomic gas, allowing the gas to expand with the pressure held constant. The gas molecules each rotate around an internal axis but do not oscillate. How much of the 1000 J goes into the increase of the gas's internal
energy? Of that amount, how much goes into \( \Delta K_{\text{rot}} \) (the kinetic energy of their rotational motion)?

**KEY IDEAS**

1. The transfer of energy as heat \( Q \) to a gas under constant pressure is related to the resulting temperature increase \( \Delta T \) via Eq. 19-46 \( Q = nC_p \Delta T \).
2. Because the gas is diatomic with molecules undergoing rotation but not oscillation, the molar specific heat is, from Fig. 19-12 and Table 19-3, \( C_p = \frac{5}{2}R \).
3. The increase \( \Delta E_{\text{int}} \) in the internal energy is the same as would occur with a constant-volume process resulting in the same \( \Delta T \). Thus, from Eq. 19-45, \( \Delta E_{\text{int}} = nC_V \Delta T \). From Fig. 19-12 and Table 19-3, we see that \( C_V = \frac{5}{2}R \).
4. For the same \( n \) and \( \Delta T \), \( \Delta E_{\text{int}} \) is greater for a diatomic gas than for a monatomic gas because additional energy is required for rotation.

**Increase in \( E_{\text{int}} \):** Let’s first get the temperature change \( \Delta T \) due to the transfer of energy as heat. From Eq. 19-46, substituting \( \frac{5}{2}R \) for \( C_p \), we have

\[
\Delta T = \frac{Q}{\frac{5}{2}nR}. \tag{19-52}
\]

We next find \( \Delta E_{\text{int}} \) from Eq. 19-45, substituting the molar specific heat \( C_V \) (= \( \frac{5}{2}R \)) for a constant-volume process and using the same \( \Delta T \). Because we are dealing with a diatomic gas, let’s call this change \( \Delta E_{\text{int, dia}} \). Equation 19-45 gives us

\[
\Delta E_{\text{int, dia}} = nC_V \Delta T = n^2R \left( \frac{Q}{n^2R} \right) = \frac{5}{2}Q
\]

\[
= 0.71428Q = 714.3 \text{ J}. \quad \text{(Answer)}
\]

In words, about 71% of the energy transferred to the gas goes into the internal energy. The rest goes into the work required to increase the volume of the gas, as the gas pushes the walls of its container outward.

**Increases in \( K \):** If we were to increase the temperature of a monatomic gas (with the same value of \( n \)) by the amount given in Eq. 19-52, the internal energy would change by a smaller amount, call it \( \Delta E_{\text{int, mon}} \), because rotational motion is not involved. To calculate that smaller amount, we still use Eq. 19-45 but now we substitute the value of \( C_V \) for a monatomic gas—namely, \( C_V = \frac{3}{2}R \). So,

\[
\Delta E_{\text{int, mon}} = n^2R \Delta T.
\]

Substituting for \( \Delta T \) from Eq. 19-52 leads us to

\[
\Delta E_{\text{int, mon}} = n^2R \left( \frac{Q}{n^2R} \right) = \frac{3}{2}Q
\]

\[
= 0.42857Q = 428.6 \text{ J}. \quad \text{(Answer)}
\]

For the monatomic gas, all this energy would go into the kinetic energy of the translational motion of the atoms. The important point here is that for a diatomic gas with the same values of \( n \) and \( \Delta T \), the same amount of energy goes into the kinetic energy of the translational motion of the molecules. The rest of \( \Delta E_{\text{int, dia}} \) (that is, the additional 285.7 J) goes into the rotational motion of the molecules. Thus, for the diatomic gas,

\[
\Delta K_{\text{trans}} = 428.6 \text{ J} \quad \text{and} \quad \Delta K_{\text{rot}} = 285.7 \text{ J}. \quad \text{(Answer)}
\]

**A Hint of Quantum Theory**

We can improve the agreement of kinetic theory with experiment by including the oscillations of the atoms in a gas of diatomic or polyatomic molecules. For example, the two atoms in the \( \text{O}_2 \) molecule of Fig. 19-13b can oscillate toward and away from each other, with the interconnecting bond acting like a spring. However, experiment shows that such oscillations occur only at relatively high temperatures of the gas—the motion is “turned on” only when the gas molecules have relatively large energies. Rotational motion is also subject to such “turning on,” but at a lower temperature.

Figure 19-14 is of help in seeing this turning on of rotational motion and oscillatory motion. The ratio \( C_V/R \) for diatomic hydrogen gas (\( \text{H}_2 \)) is plotted there against temperature, with the temperature scale logarithmic to cover several orders of magnitude. Below about 80 K, we find that \( C_V/R = 1.5 \). This result implies that only the three translational degrees of freedom of hydrogen are involved in the specific heat.
As the temperature increases, the value of $C_V/R$ gradually increases to 2.5, implying that two additional degrees of freedom have become involved. Quantum theory shows that these two degrees of freedom are associated with the rotational motion of the hydrogen molecules and that this motion requires a certain minimum amount of energy. At very low temperatures (below 80 K), the molecules do not have enough energy to rotate. As the temperature increases from 80 K, first a few molecules and then more and more of them obtain enough energy to rotate, and the value of $C_V/R$ increases, until all of the molecules are rotating and $C_V/R = 2.5$.

Similarly, quantum theory shows that oscillatory motion of the molecules requires a certain (higher) minimum amount of energy. This minimum amount is not met until the molecules reach a temperature of about 1000 K, as shown in Fig. 19-14. As the temperature increases beyond 1000 K, more and more molecules have enough energy to oscillate and the value of $C_V/R$ increases, until all of the molecules are oscillating and $C_V/R = 3.5$. (In Fig. 19-14, the plotted curve stops at 3200 K because there the atoms of a hydrogen molecule oscillate so much that they overwhelm their bond, and the molecule then disassociates into two separate atoms.)

The turning on of the rotation and vibration of the diatomic and polyatomic molecules is due to the fact that the energies of these motions are quantized, that is, restricted to certain values. There is a lowest allowed value for each type of motion. Unless the thermal agitation of the surrounding molecules provides those lowest amounts, a molecule simply cannot rotate or vibrate.

### 19-9 THE ADIABATIC EXPANSION OF AN IDEAL GAS

**Learning Objectives**

After reading this module, you should be able to . . .

19.44 On a $p-V$ diagram, sketch an adiabatic expansion (or contraction) and identify that there is no heat exchange $Q$ with the environment.

19.45 Identify that in an adiabatic expansion, the gas does work on the environment, decreasing the gas's internal energy, and that in an adiabatic contraction, work is done on the gas, increasing the internal energy.

19.46 In an adiabatic expansion or contraction, relate the initial pressure and volume to the final pressure and volume.

19.47 In an adiabatic expansion or contraction, relate the initial temperature and volume to the final temperature and volume.

19.48 Calculate the work done in an adiabatic process by integrating the pressure with respect to volume.

19.49 Identify that a free expansion of a gas into a vacuum is adiabatic but no work is done and thus, by the first law of thermodynamics, the internal energy and temperature of the gas do not change.

**Key Ideas**

- When an ideal gas undergoes a slow adiabatic volume change (a change for which $Q = 0$),

$$pV^\gamma = \text{a constant} \quad \text{(adiabatic process),}$$

- In which $\gamma (= C_p/C_V)$ is the ratio of molar specific heats for the gas.

- For a free expansion, $pV = \text{a constant}$.  

### The Adiabatic Expansion of an Ideal Gas

We saw in Module 17-2 that sound waves are propagated through air and other gases as a series of compressions and expansions; these variations in the transmission medium take place so rapidly that there is no time for energy to be transferred from one part of the medium to another as heat. As we saw in Module 18-5, a process for which $Q = 0$ is an adiabatic process. We can ensure that $Q = 0$ either by carrying out the process very quickly (as in sound waves) or by doing it (at any rate) in a well-insulated container.
Figure 19-15a shows our usual insulated cylinder, now containing an ideal gas and resting on an insulating stand. By removing mass from the piston, we can allow the gas to expand adiabatically. As the volume increases, both the pressure and the temperature drop. We shall prove next that the relation between the pressure and the volume during such an adiabatic process is

\[ pV^\gamma = \text{a constant} \quad \text{(adiabatic process),} \quad (19-53) \]

in which \( \gamma = C_p/C_V \), the ratio of the molar specific heats for the gas. On a \( p-V \) diagram such as that in Fig. 19-15b, the process occurs along a line (called an adiabat) that has the equation \( p = (\text{a constant})/V^\gamma \). Since the gas goes from an initial state \( i \) to a final state \( f \), we can rewrite Eq. 19-53 as

\[ p_iV_i^\gamma = p_fV_f^\gamma \quad \text{(adiabatic process).} \quad (19-54) \]

To write an equation for an adiabatic process in terms of \( T \) and \( V \), we use the ideal gas equation \( (pV = nRT) \) to eliminate \( p \) from Eq. 19-53, finding

\[ \left( \frac{nRT}{V} \right)V^\gamma = \text{a constant.} \]

Because \( n \) and \( R \) are constants, we can rewrite this in the alternative form

\[ TV^{\gamma-1} = \text{a constant} \quad \text{(adiabatic process),} \quad (19-55) \]

in which the constant is different from that in Eq. 19-53. When the gas goes from an initial state \( i \) to a final state \( f \), we can rewrite Eq. 19-55 as

\[ T_iV_i^{\gamma-1} = T_fV_f^{\gamma-1} \quad \text{(adiabatic process).} \quad (19-56) \]

Understanding adiabatic processes allows you to understand why popping the cork on a cold bottle of champagne or the tab on a cold can of soda causes a slight fog to form at the opening of the container. At the top of any unopened carbonated drink sits a gas of carbon dioxide and water vapor. Because the pressure of that gas is much greater than atmospheric pressure, the gas expands out into the atmosphere when the container is opened. Thus, the gas volume increases, but that means the gas must do work pushing against the atmosphere. Because the expansion is rapid, it is adiabatic, and the only source of energy for the work is the internal energy of the gas. Because the internal energy decreases,
the temperature of the gas also decreases and so does the number of water molecules that can remain as a vapor. So, lots of the water molecules condense into tiny drops of fog.

**Proof of Eq. 19-53**

Suppose that you remove some shot from the piston of Fig. 19-15a, allowing the ideal gas to push the piston and the remaining shot upward and thus to increase the volume by a differential amount \( dV \). Since the volume change is tiny, we may assume that the pressure \( p \) of the gas on the piston is constant during the change. This assumption allows us to say that the work \( dW \) done by the gas during the volume increase is equal to \( p \, dV \). From Eq. 18-27, the first law of thermodynamics can then be written as

\[
dE_{\text{int}} = Q - p \, dV. \tag{19-57}
\]

Since the gas is thermally insulated (and thus the expansion is adiabatic), we substitute 0 for \( Q \). Then we use Eq. 19-45 to substitute \( nC_V \, dT \) for \( dE_{\text{int}} \). With these substitutions, and after some rearranging, we have

\[
n \, dT = -\left(\frac{p}{C_V}\right) \, dV. \tag{19-58}
\]

Now from the ideal gas law \( (pV = nRT) \) we have

\[
p \, dV + V \, dp = nR \, dT. \tag{19-59}
\]

Replacing \( R \) with its equal, \( C_p - C_V \), in Eq. 19-59 yields

\[
n \, dT = \frac{p \, dV + V \, dp}{C_p - C_V}. \tag{19-60}
\]

Equating Eqs. 19-58 and 19-60 and rearranging then give

\[
\frac{dp}{p} + \left(\frac{C_p}{C_V}\right) \frac{dV}{V} = 0.
\]

Replacing the ratio of the molar specific heats with \( \gamma \) and integrating (see integral 5 in Appendix E) yield

\[
\ln p + \gamma \ln V = \text{a constant}.
\]

Rewriting the left side as \( \ln pV^\gamma \) and then taking the antilog of both sides, we find

\[
pV^\gamma = \text{a constant}. \tag{19-61}
\]

**Free Expansions**

Recall from Module 18-5 that a free expansion of a gas is an adiabatic process with no work or change in internal energy. Thus, a free expansion differs from the adiabatic process described by Eqs. 19-53 through 19-61, in which work is done and the internal energy changes. Those equations then do not apply to a free expansion, even though such an expansion is adiabatic.

Also recall that in a free expansion, a gas is in equilibrium only at its initial and final points; thus, we can plot only those points, but not the expansion itself, on a \( p-V \) diagram. In addition, because \( \Delta E_{\text{int}} = 0 \), the temperature of the final state must be that of the initial state. Thus, the initial and final points on a \( p-V \) diagram must be on the same isotherm, and instead of Eq. 19-56 we have

\[
T_i = T_f \quad \text{(free expansion)}. \tag{19-62}
\]
If we next assume that the gas is ideal (so that $pV = nRT$), then because there is no change in temperature, there can be no change in the product $pV$. Thus, instead of Eq. 19-53 a free expansion involves the relation

$$p_i V_i = p_f V_f \quad \text{(free expansion).} \quad (19-63)$$

**Sample Problem 19.09 Work done by a gas in an adiabatic expansion**

Initially an ideal diatomic gas has pressure $p_i = 2.00 \times 10^5$ Pa and volume $V_i = 4.00 \times 10^{-6}$ m$^3$. How much work $W$ does it do, and what is the change $\Delta E_{\text{int}}$ in its internal energy if it expands adiabatically to volume $V_f = 8.00 \times 10^{-6}$ m$^3$? Throughout the process, the molecules have rotation but no oscillation.

**Key Idea**

1. In an adiabatic expansion, no heat is exchanged between the gas and its environment, and the energy for the work done by the gas comes from the internal energy.
2. The final pressure and volume are related to the initial pressure and volume by Eq. 19-54 ($p_i V_i^\gamma = p_f V_f^\gamma$).
3. The work done by a gas in any process can be calculated by integrating the pressure with respect to the volume (the work is due to the gas pushing the walls of its container outward).

**Calculations:** We want to calculate the work by filling out this integration,

$$W = \int_{V_i}^{V_f} p \, dV, \quad (19-64)$$

but we first need an expression for the pressure as a function of volume (so that we integrate the expression with respect to volume). So, let’s rewrite Eq. 19-54 with indefinite symbols (dropping the subscripts $i$) as

$$p = \frac{1}{\gamma} V^{\gamma-1} p_i V_i^\gamma. \quad (19-65)$$

The initial quantities are given constants but the pressure $p$ is a function of the variable volume $V$. Substituting this expression into Eq. 19-64 and integrating lead us to

$$W = \int_{V_i}^{V_f} p \, dV = \int_{V_i}^{V_f} V^{\gamma-1} p_i V_i^\gamma \, dV$$

$$= p_i V_i^\gamma \int_{V_i}^{V_f} V^{-\gamma} \, dV = \frac{1}{-\gamma + 1} p_i V_i^\gamma [V^{-\gamma+1}]_{V_i}^{V_f}$$

$$= \frac{1}{-\gamma + 1} p_i V_i^\gamma [V_f^{-\gamma+1} - V_i^{-\gamma+1}]. \quad (19-66)$$

Before we substitute in given data, we must determine the ratio $\gamma$ of molar specific heats for a gas of diatomic molecules with rotation but no oscillation. From Table 19-3 we find

$$\gamma = \frac{C_p}{C_v} = \frac{7 R}{5 R} = 1.4. \quad (19-67)$$

We can now write the work done by the gas as the following (with volume in cubic meters and pressure in pascals):

$$W = \frac{1}{1.4 + 1} (2.00 \times 10^5)(4.00 \times 10^{-6})^{1.4}$$

$$\times [(8.00 \times 10^{-6})^{-1.4+1} - (4.00 \times 10^{-6})^{-1.4+1}]$$

$$= 0.48 \text{ J.} \quad \text{(Answer)}$$

The first law of thermodynamics (Eq. 18-26) tells us that $\Delta E_{\text{int}} = Q - W$. Because $Q = 0$ in the adiabatic expansion, we see that

$$\Delta E_{\text{int}} = -0.48 \text{ J.} \quad \text{(Answer)}$$

With this decrease in internal energy, the gas temperature must also decrease because of the expansion.

**Sample Problem 19.10 Adiabatic expansion, free expansion**

Initially, 1 mol of oxygen (assumed to be an ideal gas) has temperature 310 K and volume 12 L. We will allow it to expand to volume 19 L.

(a) What would be the final temperature if the gas expands adiabatically? Oxygen ($O_2$) is diatomic and here has rotation but not oscillation.

**Key Ideas**

1. When a gas expands against the pressure of its environment, it must do work.

2. When the process is adiabatic (no energy is transferred as heat), then the energy required for the work can come only from the internal energy of the gas.

3. Because the internal energy decreases, the temperature $T$ must also decrease.

**Calculations:** We can relate the initial and final temperatures and volumes with Eq. 19-56:

$$T_f V_f^{\gamma-1} = T_i V_i^{\gamma-1}. \quad (19-68)$$

Because the molecules are diatomic and have rotation but not oscillation, we can take the molar specific heats from...
In this chapter we have discussed four special processes that an ideal gas can undergo. An example of each (for a monatomic ideal gas) is shown in Fig. 19-16, and some associated characteristics are given in Table 19-4, including two process names (isobaric and isochoric) that we have not used but that you might see in other courses.

Checkpoint 5

Rank paths 1, 2, and 3 in Fig. 19-16 according to the energy transfer to the gas as heat, greatest first.

Table 19-4  Four Special Processes

<table>

We find the new pressure using Eq. 19-63, which gives us

$$p_f = p_i \frac{V_i}{V_f} = (2.0 \text{ Pa}) \frac{12 \text{ L}}{19 \text{ L}} = 1.3 \text{ Pa.}$$  (Answer)

**KEY IDEA**

The temperature does not change in a free expansion because there is nothing to change the kinetic energy of the molecules.

**Calculation:** Thus, the temperature is

$$T_f = T_i = 310 \text{ K.}$$  (Answer)

In this chapter we have discussed four special processes that an ideal gas can undergo. An example of each (for a monatomic ideal gas) is shown in Fig. 19-16, and some associated characteristics are given in Table 19-4, including two process names (isobaric and isochoric) that we have not used but that you might see in other courses.

### Problem-Solving Tactics  A Graphical Summary of Four Gas Processes

In this chapter we have discussed four special processes that an ideal gas can undergo. An example of each (for a monatomic ideal gas) is shown in Fig. 19-16, and some associated characteristics are given in Table 19-4, including two process names (isobaric and isochoric) that we have not used but that you might see in other courses.

The temperature does not change in a free expansion because there is nothing to change the kinetic energy of the molecules.

**Calculation:** Thus, the temperature is

$$T_f = T_i = 310 \text{ K.}$$  (Answer)
**Ideal Gas** An ideal gas is one for which the pressure \( p \), volume \( V \), and temperature \( T \) are related by

\[
pV = nRT \quad \text{(ideal gas law).} \tag{19-5}
\]

Here \( n \) is the number of moles of the gas present and \( R \) is a constant (8.31 J/mol·K) called the gas constant. The ideal gas law can also be written as

\[
pV = NkT, \tag{19-9}
\]

where the Boltzmann constant \( k \) is

\[
k = \frac{R}{N_A} = 1.38 \times 10^{-23} \text{ J/K}. \tag{19-7}
\]

**Work in an Isothermal Volume Change** The work done by an ideal gas during an isothermal (constant-temperature) change from volume \( V_i \) to volume \( V_f \) is

\[
W = nRT \ln \frac{V_f}{V_i} \quad \text{(ideal gas, isothermal process).} \tag{19-14}
\]

**Pressure, Temperature, and Molecular Speed** The pressure exerted by \( n \) moles of an ideal gas, in terms of the speed of its molecules, is

\[
p = \frac{nM v_{\text{rms}}^2}{3V}, \tag{19-21}
\]

where \( v_{\text{rms}} = \sqrt{\langle v^2 \rangle_{\text{av}}} \) is the root-mean-square speed of the molecules of the gas. With Eq. 19-5 this gives

\[
v_{\text{rms}} = \sqrt{\frac{3RT}{M}}. \tag{19-22}
\]

**Temperature and Kinetic Energy** The average translational kinetic energy \( K_{\text{avg}} \) per molecule of an ideal gas is

\[
K_{\text{avg}} = \frac{1}{2} kT. \tag{19-24}
\]

**Mean Free Path** The mean free path \( \lambda \) of a gas molecule is its average path length between collisions and is given by

\[
\lambda = \frac{1}{\sqrt{2\pi d^2 N/V}}, \tag{19-25}
\]

where \( N/V \) is the number of molecules per unit volume and \( d \) is the molecular diameter.

**Maxwell Speed Distribution** The Maxwell speed distribution \( P(v) \) is a function such that \( P(v) \, dv \) gives the fraction of molecules with speeds in the interval \( dv \) at speed \( v \):

\[
P(v) = 4\pi \left( \frac{M}{2\pi RT} \right)^{3/2} v^2 e^{-Mv^2/2RT}. \tag{19-27}
\]

Three measures of the distribution of speeds among the molecules of a gas are

\[
v_{\text{avg}} = \sqrt{\frac{8RT}{\pi M}} \quad \text{(average speed),} \tag{19-31}
\]

\[
v_p = \sqrt{\frac{2RT}{M}} \quad \text{(most probable speed),} \tag{19-35}
\]

and the rms speed defined above in Eq. 19-22.

**Molar Specific Heats** The molar specific heat \( C_V \) of a gas at constant volume is defined as

\[
C_V = \frac{Q}{n \Delta T} = \frac{\Delta E_{\text{int}}}{n \Delta T}, \tag{19-39, 19-41}
\]

in which \( Q \) is the energy transferred as heat to or from a sample of \( n \) moles of the gas, \( \Delta T \) is the resulting temperature change of the gas, and \( \Delta E_{\text{int}} \) is the resulting change in the internal energy of the gas. For an ideal monatomic gas,

\[
C_V = \frac{3}{2} R = 12.5 \text{ J/mol·K.} \tag{19-43}
\]

The molar specific heat \( C_p \) of a gas at constant pressure is defined to be

\[
C_p = \frac{Q}{n \Delta T}, \tag{19-46}
\]

in which \( Q, n, \) and \( \Delta T \) are defined as above. \( C_p \) is also given by

\[
C_p = C_V + R. \tag{19-49}
\]

For \( n \) moles of an ideal gas,

\[
E_{\text{int}} = nC_V T \quad \text{(ideal gas).} \tag{19-44}
\]

If \( n \) moles of a confined ideal gas undergo a temperature change \( \Delta T \) due to any process, the change in the internal energy of the gas is

\[
\Delta E_{\text{int}} = nC_V \Delta T \quad \text{(ideal gas, any process).} \tag{19-45}
\]

**Degrees of Freedom and \( C_V \)** The equipartition of energy theorem states that every degree of freedom of a molecule has an energy \( \frac{1}{2} kT \) per molecule (= \( \frac{1}{2} RT \) per mole). If \( f \) is the number of degrees of freedom, then \( E_{\text{int}} = (f/2)nRT \) and

\[
C_V = \left( \frac{f}{2} \right) R = 4.16f \text{ J/mol·K.} \tag{19-51}
\]

For monatomic gases \( f = 3 \) (three translational degrees); for diatomic gases \( f = 5 \) (three translational and two rotational degrees).

**Adiabatic Process** When an ideal gas undergoes an adiabatic volume change (a change for which \( Q = 0 \)),

\[
pV^\gamma = \text{a constant} \quad \text{(adiabatic process),} \tag{19-53}
\]

in which \( \gamma = C_p/C_V \) is the ratio of molar specific heats for the gas. For a free expansion, however, \( pV = \text{a constant} \).

### Questions

1. For four situations for an ideal gas, the table gives the energy transferred to or from the gas as heat \( Q \) and either the work \( W \) done by the gas or the work \( W_{\text{on}} \) done on the gas, all in joules. Rank the four situations in terms of the temperature change of the gas, most positive first.

2. In the \( p-V \) diagram of Fig. 19-17, the gas does 5 J of work when taken along isotherm \( ab \) and 4 J when taken along adiabat \( bc \). What is the change

![Figure 19-17](image-url)
in the internal energy of the gas when it is taken along the straight path from \(a\) to \(c\)?

3. For a temperature increase of \(\Delta T_1\), a certain amount of an ideal gas requires 30 J when heated at constant volume and 50 J when heated at constant pressure. How much work is done by the gas in the second situation?

4. The dot in Fig. 19-18a represents the initial state of a gas, and the vertical line through the dot divides the \(p\)-\(V\) diagram into regions 1 and 2. For the following processes, determine whether the work \(W\) done by the gas is positive, negative, or zero: (a) the gas moves up along the vertical line, (b) it moves down along the vertical line, (c) it moves to anywhere in region 1, and (d) it moves to anywhere in region 2.

5. A certain amount of energy is to be transferred as heat to 1 mol of a monatomic gas (a) at constant pressure and (b) at constant volume, and to 1 mol of a diatomic gas (c) at constant pressure and (d) at constant volume. Figure 19-19 shows four paths from an initial point to four final points on a \(p\)-\(V\) diagram for the two gases. Which path goes with which process? (e) Are the molecules of the diatomic gas rotating?

6. The dot in Fig. 19-18b represents the initial state of a gas, and the isotherm through the dot divides the \(p\)-\(V\) diagram into regions 1 and 2. For the following processes, determine whether the change \(\Delta E_{\text{int}}\) in the internal energy of the gas is positive, negative, or zero: (a) the gas moves up along the isotherm, (b) it moves down along the isotherm, (c) it moves to anywhere in region 1, and (d) it moves to anywhere in region 2.

7. (a) Rank the four paths of Fig. 19-16 according to the work done by the gas, greatest first. (b) Rank paths 1, 2, and 3 according to the change in the internal energy of the gas, most positive first and most negative last.

8. The dot in Fig. 19-18c represents the initial state of a gas, and the adiabat through the dot divides the \(p\)-\(V\) diagram into regions 1 and 2. For the following processes, determine whether the corresponding change \(Q\) is positive, negative, or zero: (a) the gas moves up along the adiabat, (b) it moves down along the adiabat, (c) it moves to anywhere in region 1, and (d) it moves to anywhere in region 2.

9. An ideal diatomic gas, with molecular rotation but without any molecular oscillation, loses a certain amount of energy as heat \(Q\). Is the resulting decrease in the internal energy of the gas greater if the loss occurs in a constant-volume process or in a constant-pressure process?

10. Does the temperature of an ideal gas increase, decrease, or stay the same during (a) an isothermal expansion, (b) an expansion at constant pressure, (c) an adiabatic expansion, and (d) an increase in pressure at constant volume?

---

**Module 19-1 Avogadro’s Number**

1. Find the mass in kilograms of \(7.50 \times 10^{24}\) atoms of arsenic, which has a molar mass of 74.9 g/mol.

2. Gold has a molar mass of 197 g/mol. (a) How many moles of gold are in a 2.50 g sample of pure gold? (b) How many atoms are in the sample?

**Module 19-2 Ideal Gases**

3. Oxygen gas having a volume of 1000 cm\(^3\) at 40.0°C and 1.01 \(\times\) 10\(^5\) Pa expands until its volume is 1500 cm\(^3\) and its pressure is 1.06 \(\times\) 10\(^5\) Pa. Find (a) the number of moles of oxygen present and (b) the final temperature of the sample.

4. A quantity of ideal gas at 10.0°C and 100 kPa occupies a volume of 2.50 m\(^3\). (a) How many moles of the gas are present? (b) If the pressure is now raised to 300 kPa and the temperature is raised to 30.0°C, how much volume does the gas occupy? Assume no leaks.

5. The best laboratory vacuum has a pressure of about 1.00 \(\times\) 10\(^{-18}\) atm, or 1.01 \(\times\) 10\(^{-13}\) Pa. How many gas molecules are there per cubic centimeter in such a vacuum at 293 K?

6. **Water bottle in a hot car.** In the American Southwest, the temperature in a closed car parked in sunlight during the summer can be high enough to burn flesh. Suppose a bottle of water at a refrigerator temperature of 5.00°C is opened, then closed, and then left in a closed car with an internal temperature of 75.0°C. Neglecting the thermal expansion of the water and the bottle, find the pressure in the air pocket trapped in the bottle. (The pressure can be enough to push the bottle cap past the threads that are intended to keep the bottle closed.)

7. Suppose 1.80 mol of an ideal gas is taken from a volume of 3.00 m\(^3\) to a volume of 1.50 m\(^3\) via an isothermal compression at 30°C. (a) How much energy is transferred as heat during the compression, and (b) is the transfer to or from the gas?

8. Compute (a) the number of moles and (b) the number of molecules in 1.00 cm\(^3\) of an ideal gas at a pressure of 100 Pa and a temperature of 220 K.

9. An automobile tire has a volume of 1.64 \(\times\) 10\(^{-2}\) m\(^3\) and contains air at a gauge pressure (pressure above atmospheric pressure) of 165 kPa when the temperature is 0.00°C. What is the gauge...
pressure of the air in the tires when its temperature rises to 27.0°C and its volume increases to $1.67 \times 10^{-2} \text{ m}^3$? Assume atmospheric pressure is $1.01 \times 10^5 \text{ Pa}$.

**10** A container encloses 2 mol of an ideal gas that has molar mass $M_1$ and 0.5 mol of a second ideal gas that has molar mass $M_2 = 3M_1$. What fraction of the total pressure on the container wall is attributable to the second gas? (The kinetic theory explanation of pressure leads to the experimentally discovered law of partial pressures for a mixture of gases that do not react chemically: The total pressure exerted by the mixture is equal to the sum of the pressures that the several gases would exert separately if each were to occupy the vessel alone. The molecule–vessel collisions of one type would not be altered by the presence of another type.)

**11 SSM IUW WWW** Air that initially occupies 0.140 m$^3$ at a gauge pressure of 103.0 kPa is expanded isothermally to a pressure of 101.3 kPa and then cooled at constant pressure until it reaches its initial volume. Compute the work done by the air. (Gauge pressure is the difference between the actual pressure and atmospheric pressure.)

**12** Submarine rescue. When the U.S. submarine Squalus became disabled at a depth of 80 m, a cylindrical chamber was lowered from a ship to rescue the crew. The chamber had a radius of 1.00 m and a height of 4.00 m, was open at the bottom, and held two rescuers. It slid along a guide cable that a diver had attached to a hatch on the submarine. Once the chamber reached the hatch and clamped to the hull, the crew could escape into the chamber. During the descent, air was released from tanks to prevent water from flooding the chamber. Assume that the interior air pressure matched the water pressure at depth $h$ as given by $p_0 + ho g h$, where $p_0 = 1.000 \text{ atm}$ is the surface pressure and $\rho = 1024 \text{ kg/m}^3$ is the density of seawater. Assume a surface temperature of 20.0°C and a submerged water temperature of $-30.0^\circ \text{C}$. (a) What is the air volume in the chamber at the surface? (b) If air had not been released from the tanks, what would have been the air volume in the chamber at depth $h = 80.0 \text{ m}$? (c) How many moles of air were needed to be released to maintain the original air volume in the chamber?

**13** A sample of an ideal gas is taken through the cyclic process abca shown in Fig. 19.20. The scale of the vertical axis is set by $V_c = 0.30 \text{ m}^3$ and the scale of the horizontal axis is set by $Q_c = 1200 \text{ J}$.

### Figure 19-20 Problem 13.

![Figure 19-20](image)

**14** In the temperature range 310 K to 330 K, the pressure $p$ of a certain nonideal gas is related to volume $V$ and temperature $T$ by

$$ p = (24.9 \text{ J/K}) \frac{T}{V} - (0.00662 \text{ J/K}^2) \frac{T^2}{V}. $$

How much work is done by the gas if its temperature is raised from 315 K to 325 K while the pressure is held constant?

**15** Suppose 0.825 mol of an ideal gas undergoes an isothermal expansion as energy is added to it as heat $Q$. If Fig. 19.21 shows the final volume $V_f$ versus $Q$, what is the gas temperature? The scale of the vertical axis is set by $V_p = 0.30 \text{ m}^3$ and the scale of the horizontal axis is set by $Q_p = 1200 \text{ J}$.

### Figure 19-21 Problem 15.

![Figure 19-21](image)

**16** An air bubble of volume 20 cm$^3$ is at the bottom of a lake 40 m deep, where the temperature is 4.0°C. The bubble rises to the surface, which is at a temperature of 20°C. Take the temperature of the bubble’s air to be the same as that of the surrounding water. Just as the bubble reaches the surface, what is its volume?

**17** Container A in Fig. 19.22 holds an ideal gas at a pressure of $5.0 \times 10^5 \text{ Pa}$ and a temperature of 300 K. It is connected by a thin tube (and a closed valve) to container B, with four times the volume of A. Container B holds the same ideal gas at a pressure of $1.0 \times 10^5 \text{ Pa}$ and a temperature of 400 K. The valve is opened to allow the pressures to equalize, but the temperature of each container is maintained. What then is the pressure?

### Module 19-3 Pressure, Temperature, and RMS Speed

**18** The temperature and pressure in the Sun’s atmosphere are $2.00 \times 10^6 \text{ K}$ and 0.0300 Pa. Calculate the rms speed of free electrons (mass $9.11 \times 10^{-31} \text{ kg}$) there, assuming they are an ideal gas.

**19** (a) Compute the rms speed of a nitrogen molecule at 20.0°C. The molar mass of nitrogen molecules $(N_2)$ is given in Table 19-1. At what temperatures will the rms speed be (b) half that value and (c) twice that value?

**20** Calculate the rms speed of helium atoms at 1000 K. See Appendix F for the molar mass of helium atoms.

**21** The lowest possible temperature in outer space is 2.7 K. What is the rms speed of hydrogen molecules at this temperature? (The molar mass is given in Table 19-1.)

**22** Find the rms speed of argon atoms at 313 K. See Appendix F for the molar mass of argon atoms.

**23** A beam of hydrogen molecules $(H_2)$ is directed toward a wall, at an angle of 55° with the normal to the wall. Each molecule in the beam has a speed of 1.0 km/s and a mass of $3.3 \times 10^{-24} \text{ g}$. The beam strikes the wall over an area of 2.0 cm$^2$, at the rate of $10^{22}$ molecules per second. What is the beam’s pressure on the wall?

**24** At 273 K and $1.00 \times 10^{-2} \text{ atm}$, the density of a gas is $1.24 \times 10^{-3} \text{ g/cm}^3$. (a) Find $v_{rms}$ for the gas molecules. (b) Find the molar mass of the gas and (c) identify the gas. See Table 19-1.

### Module 19-4 Translational Kinetic Energy

**25** Determine the average value of the translational kinetic energy of the molecules of an ideal gas at temperatures (a) 0.00°C...
and (b) 100°C. What is the translational kinetic energy per mole of an ideal gas at (c) 0.00°C and (d) 100°C?

26. What is the average translational kinetic energy of nitrogen molecules at 1600 K?

27. Water standing in the open at 32.0°C evaporates because of the escape of some of the surface molecules. The heat of vaporization (539 cal/g) is approximately equal to εn, where ε is the average energy of the escaping molecules and n is the number of molecules per gram. (a) Find ε. (b) What is the ratio of ε to the average kinetic energy of H₂O molecules, assuming the latter is related to temperature in the same way as it is for gases?

Module 19-5 Mean Free Path

28. At what frequency would the wavelength of sound in air be equal to the mean free path of oxygen molecules at 1.0 atm pressure and 0.00°C? The molecular diameter is 3.0 x 10⁻⁸ cm.

29. SSM The atmospheric density at an altitude of 2500 km is about 1 molecule/cm². (a) Assuming the molecular diameter of 2.0 x 10⁻⁸ cm, find the mean free path predicted by Eq. 19-25. (b) Explain whether the predicted value is meaningful.

30. The mean free path of nitrogen molecules at 0.0°C and 1.0 atm is 0.80 x 10⁻⁵ cm. At this temperature and pressure there are 2.7 x 10¹⁵ molecules/cm³. What is the molecular diameter?

31. In a certain particle accelerator, protons travel around a circular path of diameter 23.0 m in an evacuated chamber, whose residual gas is at 295 K and 1.00 x 10⁻⁶ torr pressure. (a) Calculate the number of gas molecules per cubic centimeter at this pressure. (b) What is the mean free path of the gas molecules if the molecular diameter is 2.00 x 10⁻⁸ cm?

32. At 20°C and 750 torr pressure, the mean free paths for argon gas (Ar) and nitrogen gas (N₂) are λAr = 9.9 x 10⁻⁶ cm and λN₂ = 27.5 x 10⁻⁶ cm. (a) Find the ratio of the diameter of an Ar atom to that of an N₂ molecule. What is the mean free path of argon at (b) 20°C and 150 torr, and (c) -40°C and 750 torr?

Module 19-6 The Distribution of Molecular Speeds

33. SSM The speeds of 10 molecules are 2.0, 3.0, 4.0, . . . , 11 km/s. What are their (a) average speed and (b) rms speed?

34. The speeds of 22 particles are as follows (N_i represents the number of particles that have speed vi):

<table>
<thead>
<tr>
<th>N_i (cm/s)</th>
<th>2</th>
<th>4</th>
<th>6</th>
<th>8</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_i (m/s)</td>
<td>1.0</td>
<td>2.0</td>
<td>3.0</td>
<td>4.0</td>
<td>5.0</td>
</tr>
</tbody>
</table>

What are (a) v_avg, (b) v_rms, and (c) v_p?

35. Ten particles are moving with the following speeds: four at 200 m/s, two at 500 m/s, and four at 600 m/s. Calculate their (a) average and (b) rms speeds. (c) Is v_rms > v_avg?

36. The most probable speed of the molecules in a gas at temperature T is equal to the rms speed of the molecules at temperature T. Find T_2/T_1.

37. SSM WWW Figure 19-23 shows a hypothetical speed distribution for a sample of N gas particles (note that P(v) = 0 for speed v > 2v_0). What are the values of (a) v_min, (b) v_avg/v_0, and (c) v_{rms}/v_0? (d) What fraction of the particles has a speed between 1.5v_0 and 2.0v_0? What is the average translational kinetic energy of hydrogen gas at 1000 K?

38. Figure 19-24 gives the probability distribution for nitrogen gas. The scale of the horizontal axis is set by v_i = 1200 m/s. What are the (a) gas temperature and (b) rms speed of the molecules?

39. At what temperature does the rms speed of (a) H₂ (molecular hydrogen) and (b) O₂ (molecular oxygen) equal the escape speed from Earth (Table 13-2)? At what temperature does the rms speed of (c) H₂ and (d) O₂ equal the escape speed from the Moon (where the gravitational acceleration at the surface has magnitude 0.16g)? Considering the answers to parts (a) and (b), should there be much (e) hydrogen and (f) oxygen high in Earth's upper atmosphere, where the temperature is about 1000 K?

40. Two containers are at the same temperature. The first contains gas with pressure p₁, molecular mass m₁, and rms speed v_{rms₁}. The second contains gas with pressure 2.0p₁, molecular mass m₂, and average speed v_{avg₂} = 2.0v_{rms₁}. Find the mass ratio m₁/m₂.

41. A hydrogen molecule (diameter 1.0 x 10⁻⁸ cm), traveling at the rms speed, escapes from a 4000 K furnace into a chamber containing cold argon atoms (diameter 3.0 x 10⁻⁸ cm) at a density of 4.0 x 10¹⁷ atoms/cm³. (a) What is the speed of the hydrogen molecule? (b) If it collides with an argon atom, what is the closest their centers can be, considering each as spherical? (c) What is the initial number of collisions per second experienced by the hydrogen molecule? (Hint: Assume that the argon atoms are stationary. Then the mean free path of the hydrogen molecule is given by Eq. 19-26 and not Eq. 19-25.)

Module 19-7 The Molar Specific Heats of an Ideal Gas

42. What is the internal energy of 1.0 mol of an ideal monatomic gas at 273 K?

43. The temperature of 3.00 mol of an ideal diatomic gas is increased by 40.0°C without the pressure of the gas changing. The molecules in the gas rotate but do not oscillate. (a) How much energy is transferred to the gas as heat? (b) What is the change in the internal energy of the gas? (c) How much work is done by the gas? (d) By how much does the rotational kinetic energy of the gas increase?

44. One mole of an ideal diatomic gas goes from a to c along the diagonal path in Fig. 19-25. The scale of the vertical axis is set by p_{ab} = 5.0 kPa and p_c = 2.0 kPa, and the scale of the horizontal axis is set by V_a = 4.0 m³ and V_c = 2.0 m³. During the transition, (a) what is the change in internal energy of the gas, and (b) how
much energy is added to the gas as heat? (c) How much heat is required if the gas goes from \( a \) to \( c \) along the indirect path \( abc \)?

The mass of a gas molecule can be computed from its specific heat at constant volume \( c_V \). Take \( c_V = 0.075 \text{ cal/g \cdot C} \) for argon and calculate (a) the mass of an argon atom and (b) the molar mass of argon.

Under constant pressure, the temperature of 2.00 mol of an ideal monatomic gas is raised 15.0 K. What are (a) the work \( W \) done by the gas, (b) the energy transferred as heat \( Q \), (c) the change \( \Delta E_{\text{int}} \) in the internal energy of the gas, and (d) the change \( \Delta K \) in the average kinetic energy per atom?

The temperature of 2.00 mol of an ideal monatomic gas is raised 15.0 K at constant volume. What are (a) the work \( W \) done by the gas, (b) the energy transferred as heat \( Q \), (c) the change \( \Delta E_{\text{int}} \) in the internal energy of the gas, and (d) the change \( \Delta K \) in the average kinetic energy per atom?

When 20.9 J was added as heat to a particular ideal gas, the volume of the gas changed from 50.0 cm\(^3\) to 100 cm\(^3\) while the pressure remained at 1.00 atm. (a) How much did the internal energy of the gas change? If the quantity of gas present was 2.00 \times 10^{-3} \text{ mol}, find (b) \( C_p \) and (c) \( C_V \).

A container holds a mixture of three nonreacting gases: 2.40 mol of gas 1 with \( C_{V1} = 12.0 \text{ J/mol \cdot K} \), 1.50 mol of gas 2 with \( C_{V2} = 12.8 \text{ J/mol \cdot K} \), and 3.20 mol of gas 3 with \( C_{V3} = 20.0 \text{ J/mol \cdot K} \). What is \( C_V \) of the mixture?

Module 19-8 Degrees of Freedom and Molar Specific Heats

We give 70 J as heat to a diatomic gas, which then expands at constant pressure. The gas molecules rotate but do not oscillate. By how much does the internal energy of the gas increase?

When 1.0 mol of oxygen (O\(_2\)) gas is heated at constant pressure starting at 0°C, how much energy must be added to the gas as heat to double its volume? (The molecules rotate but do not oscillate.)

Suppose 12.0 g of oxygen (O\(_2\)) gas is heated at constant atmospheric pressure from 25.0°C to 125°C. (a) How many moles of oxygen are present? (See Table 19-1 for the molar mass.) (b) How much energy is transferred as heat to the oxygen as heat? (The molecules rotate but do not oscillate.) (c) What fraction of the heat is used to raise the internal energy of the oxygen?

Suppose 4.00 mol of an ideal diatomic gas, with molecular rotation but not oscillation, experienced a temperature increase of 60.0 K under constant-pressure conditions. What are (a) the energy transferred as heat \( Q \), (b) the change \( \Delta E_{\text{int}} \) in internal energy of the gas, (c) the work \( W \) done by the gas, and (d) the change \( \Delta K \) in the total translational kinetic energy of the gas?

Module 19-9 The Adiabatic Expansion of an Ideal Gas

We know that for an adiabatic process \( pV^\gamma = \text{constant} \). Evaluate “a constant” for an adiabatic process involving exactly 2.0 mol of an ideal gas passing through the state having exactly \( p = 1.0 \text{ atm} \) and \( T = 300 \text{ K} \). Assume a diatomic gas whose molecules rotate but do not oscillate.

A certain gas occupies a volume of 4.3 L at a pressure of 1.2 atm and a temperature of 310 K. It is compressed adiabatically to a volume of 0.76 L. Determine (a) the final pressure and (b) the final temperature, assuming the gas to be an ideal gas for which \( \gamma = 1.4 \).

Suppose 1.00 L of a gas with \( \gamma = 1.30 \), initially at 273 K and 1.00 atm, is suddenly compressed adiabatically to half its initial volume. Find its final (a) pressure and (b) temperature. (c) If the gas is then cooled to 273 K at constant pressure, what is its final volume?

The volume of an ideal gas is adiabatically reduced from 200 L to 74.3 L. The initial pressure and temperature are 1.00 atm and 300 K. The final pressure is 4.00 atm. (a) Is the gas monatomic, diatomic, or polyatomic? (b) What is the final temperature? (c) How many moles are in the gas?

Opening champagne. In a bottle of champagne, the pocket of gas (primarily carbon dioxide) between the liquid and the cork is at pressure of \( p_i = 5.00 \text{ atm} \). When the cork is pulled from the bottle, the gas undergoes an adiabatic expansion until its pressure matches the ambient air pressure of 1.00 atm. Assume that the ratio of the molar specific heats is \( \gamma = \frac{5}{3} \). If the gas has initial temperature \( T_i = 5.00 \text{°C} \), what is its temperature at the end of the adiabatic expansion?

Figure 19-26 shows two paths that may be taken by a gas from an initial point \( i \) to a final point \( f \). Path 1 consists of an isothermal expansion (work is 50 J in magnitude), an adiabatic expansion (work is 40 J in magnitude), an isothermal compression (work is 30 J in magnitude), and then an adiabatic compression (work is 25 J in magnitude). What is the change in the internal energy of the gas if the gas goes from point \( i \) to point \( f \) along path 2?

Adiabatic wind. The normal airflow over the Rocky Mountains is west to east. The air loses much of its moisture content and is chilled as it climbs the western side of the mountains. When it descends on the eastern side, the increase in pressure toward lower altitudes causes the temperature to increase. The flow, then called a chinook wind, can rapidly raise the air temperature at the base of the mountains. Assume that the air pressure \( p \) depends on altitude \( y \) according to \( p = p_0 \exp\left(-\frac{ay}{y_1}\right) \), where \( p_0 = 1.00 \text{ atm} \) and \( a = 1.16 \times 10^{-4} \text{ m}^{-1} \). Also assume that the ratio of the molar specific heats is \( \gamma = \frac{5}{3} \). A parcel of air with an initial temperature of \(-5.00 \text{°C} \) descends adiabatically from \( y_1 = 4267 \text{ m} \) to \( y = 1567 \text{ m} \). What is its temperature at the end of the descent?

A gas is to be expanded from initial state \( i \) to final state \( f \) along either path 1 or path 2 on a \( p-V \) diagram. Path 1 consists of three steps: an isothermal expansion (work is 40 J in magnitude), an adiabatic expansion (work is 20 J in magnitude), and another isothermal expansion (work is 30 J in magnitude). Path 2 consists of two steps: a pressure reduction at constant volume and an expansion at constant pressure. What is the change in the internal energy of the gas along path 2?

An ideal diatomic gas, with rotation but no oscillation, undergoes an adiabatic compression. Its initial pressure and volume are
1.20 atm and 0.200 m$^3$. Its final pressure is 2.40 atm. How much work is done by the gas?

**63** Figure 19-27 shows a cycle undergone by 1.00 mol of an ideal monatomic gas. The temperatures are $T_1 = 300 \, \text{K}$, $T_2 = 600 \, \text{K}$, and $T_3 = 455 \, \text{K}$. For $1 \to 2$, what are (a) heat $Q$, (b) the change in internal energy $\Delta E_{\text{int}}$, and (c) the work done $W$? For $2 \to 3$, what are (d) $Q$, (e) $\Delta E_{\text{int}}$, and (f) $W$? For $3 \to 1$, what are (g) $Q$, (h) $\Delta E_{\text{int}}$, and (i) $W$? For the full cycle, what are (j) $Q$, (k) $\Delta E_{\text{int}}$, and (l) $W$? The initial pressure at point 1 is 1.00 atm (= 1.013 × 10$^5$ Pa). What are the (m) volume and (n) pressure at point 2 and the (o) volume and (p) pressure at point 3?

**Additional Problems**

**64** Calculate the work done by an external agent during an isothermal compression of 1.00 mol of oxygen from a volume of 22.4 L at 0°C and 1.00 atm to a volume of 16.8 L.

**65** An ideal gas undergoes an adiabatic compression from $p = 1.0 \, \text{atm}$, $V = 1.0 \times 10^4 \, \text{L}$, $T = 0.0^\circ \text{C}$ to $p = 1.0 \times 10^5 \, \text{atm}$, $V = 1.0 \times 10^3 \, \text{L}$. (a) Is the gas monatomic, diatomic, or polyatomic? (b) What is its final temperature? (c) How many moles of gas are present? What is the total translational kinetic energy per molecule (d) before and (e) after the compression? (f) What is the ratio of the squares of the rms speeds before and after the compression?

**66** An ideal gas consists of 1.50 mol of diatomic molecules that rotate but do not oscillate. The molecular diameter is 250 pm. The gas is expanded at a constant pressure of 1.50 × 10$^{-5}$ Pa, with a transfer of 200 J as heat. What is the change in the mean free path of the molecules?

**67** An ideal monatomic gas initially has a temperature of 330 K and a pressure of 6.00 atm. It is to expand from volume 500 cm$^3$ to volume 1500 cm$^3$. If the expansion is isothermal, what are (a) the final pressure and (b) the work done by the gas? If, instead, the expansion is adiabatic, what are (c) the final pressure and (d) the work done by the gas?

**68** In an interstellar gas cloud at 50.0 K, the pressure is $1.00 \times 10^{-8}$ Pa. Assuming that the molecular diameters of the gases in the cloud are all 20.0 nm, what is their mean free path?

**69** The envelope and basket of a hot-air balloon have a combined weight of 2.45 kN, and the envelope has a capacity (volume) of 2.18 × 10$^3$ m$^3$. When it is fully inflated, what should be the temperature of the enclosed air to give the balloon a lifting capacity (force) of 2.67 kN (in addition to the balloon’s weight)? Assume that the surrounding air, at 20.0°C, has a weight per unit volume of 11.9 N/m$^3$ and a molecular mass of 0.028 kg/mol, and is at a pressure of 1.0 atm.

**70** An ideal gas, at initial temperature $T_1$ and initial volume 2.0 m$^3$, is expanded adiabatically to a volume of 4.0 m$^3$, then expanded isothermally to a volume of 10 m$^3$, and then compressed adiabatically back to $T_1$. What is its final volume?

**71** The temperature of 2.00 mol of an ideal monatomic gas is raised 15.0 K in an adiabatic process. What are (a) the work $W$ done by the gas, (b) the energy transferred as heat $Q$, (c) the change $\Delta E_{\text{int}}$ in internal energy of the gas, and (d) the change $\Delta K$ in the average kinetic energy per atom?

**72** At what temperature do atoms of helium gas have the same rms speed as molecules of hydrogen gas at 20.0°C? (The molar masses are given in Table 19-1.)

**73** At what frequency do molecules (diameter 290 pm) collide in (an ideal) oxygen gas (O$_2$) at temperature 400 K and pressure 2.00 atm?

**74** (a) What is the number of molecules per cubic meter in air at 20°C and at a pressure of 1.0 atm (= 1.01 × 10$^5$ Pa)? (b) What is the mass of 1.0 m$^3$ of this air? Assume that 75% of the molecules are nitrogen (N$_2$) and 25% are oxygen (O$_2$).

**75** The temperature of 3.00 mol of a gas with $C_V = 6.00$ cal/mol·K is to be raised 50.0 K. If the process is at constant volume, what are (a) the energy transferred as heat $Q$, (b) the work $W$ done by the gas, (c) the change $\Delta E_{\text{int}}$ in internal energy of the gas, and (d) the change $\Delta K$ in the total translational kinetic energy? If the process is at constant pressure, what are (a) $Q$, (b) $W$, (c) $\Delta E_{\text{int}}$, and (d) $\Delta K$? If the process is adiabatic, what are (i) $Q$, (j) $W$, (k) $\Delta E_{\text{int}}$, and (l) $\Delta K$?

**76** During a compression at a constant pressure of 250 Pa, the volume of an ideal gas decreases from 0.80 m$^3$ to 0.20 m$^3$. The initial temperature is 360 K, and the gas loses 210 J as heat. What are (a) the change in the internal energy of the gas and (b) the final temperature of the gas?

**77** Figure 19-28 shows a hypothetical speed distribution for particles of a certain gas: $P(v) = C v^2$ for $0 < v \leq v_0$ and $P(v) = 0$ for $v > v_0$. Find (a) an expression for $C$ in terms of $v_0$, (b) the average speed of the particles, and (c) their rms speed.

**78** (a) An ideal gas initially at pressure $p_0$ undergoes a free expansion until its volume is 3.00 times its initial volume. What then is the ratio of its pressure to $p_0$? (b) The gas is next slowly and adiabatically compressed back to its original volume. The pressure after compression is $(3.00)^{1/3} p_0$. Is the gas monatomic, diatomic, or polyatomic? (c) What is the ratio of the average kinetic energy per molecule in this final state to that in the initial state?

**79** An ideal gas undergoes isothermal compression from an initial volume of 4.00 m$^3$ to a final volume of 3.00 m$^3$. There is 3.50 mol of the gas, and its temperature is 10.0°C. (a) How much work is done by the gas? (b) How much energy is transferred as heat between the gas and its environment?

**80** Oxygen (O$_2$) gas at 273 K and 1.0 atm is confined to a cubical container 10 cm on a side. Calculate $\Delta U_c/K_{\text{avg}}$, where $\Delta U_c$ is the change in the gravitational potential energy of an oxygen molecule falling the height of the box and $K_{\text{avg}}$ is the molecule’s average translational kinetic energy.

**81** An ideal gas is taken through a complete cycle in three steps: adiabatic expansion with work equal to 125 J, isothermal contraction at 325 K, and increase in pressure at constant volume. (a) Draw a $p-V$ diagram for the three steps. (b) How much energy is transferred as heat in step 3, and (c) is it transferred to or from the gas?

**82** (a) What is the volume occupied by 1.00 mol of an ideal gas at standard conditions—that is, 1.00 atm (= 1.01 × 10$^5$ Pa) and 273 K? (b) Show that the number of molecules per cubic centimeter (the Loschmidt number) at standard conditions is 2.69 × 10$^{19}$.

**83** A sample of ideal gas expands from an initial pressure
and volume of 32 atm and 1.0 L to a final volume of 4.0 L. The initial temperature is 300 K. If the gas is monatomic and the expansion isothermal, what are the (a) final pressure \( p_f \), (b) final temperature \( T_f \), and (c) work \( W \) done by the gas? If the gas is monatomic and the expansion adiabatic, what are (d) \( p_f \), (e) \( T_f \), and (f) \( W \)? If the gas is diatomic and the expansion adiabatic, what are (g) \( p_f \), (h) \( T_f \), and (i) \( W \)?

84 An ideal gas with 3.00 mol is initially in state 1 with pressure \( p_1 = 20.0 \text{ atm} \) and volume \( V_1 = 1500 \text{ cm}^3 \). First it is taken to state 2 with pressure \( p_2 = 1.50 p_1 \) and volume \( V_2 = 2.00 V_1 \). Then it is taken to state 3 with pressure \( p_3 = 2.00 p_1 \) and volume \( V_3 = 0.500 V_1 \). What is the temperature of the gas in (a) state 1 and (b) state 2? (c) What is the net change in internal energy from state 1 to state 3?

85 A steel tank contains 300 g of ammonia gas (NH\(_3\)) at a pressure of \( 1.35 \times 10^6 \text{ Pa} \) and a temperature of 77°C. (a) What is the volume of the tank in liters? (b) Later the temperature is 22°C and the pressure is \( 8.7 \times 10^5 \text{ Pa} \). How many grams of gas have leaked out of the tank?

86 In an industrial process the volume of 25.0 mol of a monatomic ideal gas is reduced at a uniform rate from 0.616 m\(^3\) to 0.308 m\(^3\) in 2.00 h while its temperature is increased at a uniform rate from 27.0°C to 450°C. Throughout the process, the gas passes through thermodynamic equilibrium states. What are (a) the cumulative work done on the gas, (b) the cumulative energy absorbed by the gas as heat, and (c) the molar specific heat for the process? (Hint: To evaluate the integral for the work, you might use

\[
\int \frac{a + bx}{A + Bx} \, dx = \frac{bx}{B} + \frac{aB - bA}{B^2} \ln(A + Bx),
\]

an indefinite integral.) Suppose the process is replaced with a two-step process that reaches the same final state. In step 1, the gas volume is reduced at constant temperature, and in step 2 the temperature is increased at constant volume. For this process, what are (d) the cumulative work done on the gas, (e) the cumulative energy absorbed by the gas as heat, and (f) the molar specific heat for the process?

87 Figure 19-29 shows a cycle consisting of five paths: \( AB \) is isothermal at 300 K, \( BC \) is adiabatic with work \( = 5.0 \text{ J} \), \( CD \) is at a constant pressure of 5 atm, \( DE \) is isothermal, and \( EA \) is adiabatic with a change in internal energy of 8.0 J. What is the change in internal energy of the gas along path \( CD \)?

88 An ideal gas initially at 300 K is compressed at a constant pressure of 25 N/m\(^2\) from a volume of 3.0 m\(^3\) to a volume of 1.8 m\(^3\). In the process, 75 J is lost by the gas as heat. What are (a) the change in internal energy of the gas and (b) the final temperature of the gas?

89 A pipe of length \( L = 25.0 \text{ m} \) that is open at one end contains air at atmospheric pressure. It is thrust vertically into a freshwater lake until the water rises halfway up in the pipe (Fig. 19-30). What is the depth \( h \) of the lower end of the pipe? Assume that the temperature is the same everywhere and does not change.

90 In a motorcycle engine, a piston is forced down toward the crankshaft when the fuel in the top of the piston’s cylinder undergoes combustion. The mixture of gaseous combustion products then expands adiabatically as the piston descends. Find the average power in (a) watts and (b) horsepower that is involved in this expansion when the engine is running at 4000 rpm, assuming that the gauge pressure immediately after combustion is 15 atm, the initial volume is 50 cm\(^3\), and the volume of the mixture at the bottom of the stroke is 250 cm\(^3\). Assume that the gases are diatomic and that the time involved in the expansion is one-half of the total cycle.

91 For adiabatic processes in an ideal gas, show that (a) the bulk modulus is given by

\[
B = -V \frac{dp}{dV} = \gamma p,
\]

where \( \gamma = C_p/C_v \). (See Eq. 17-2.) (b) Then show that the speed of sound in the gas is

\[
v_s = \sqrt{\frac{\gamma p}{\rho}} = \sqrt{\frac{\gamma RT}{M}},
\]

where \( \rho \) is the density, \( T \) is the temperature, and \( M \) is the molar mass. (See Eq. 17-3.)

92 Air at 0.000°C and 1.00 atm pressure has a density of \( 1.29 \times 10^{-3} \text{ g/cm}^3 \) and the speed of sound is 331 m/s at that temperature. Compute the ratio \( \gamma \) of the molar specific heats of air. (Hint: See Problem 91.)

93 The speed of sound in different gases at a certain temperature \( T \) depends on the molar mass of the gases. Show that

\[
\frac{v_1}{v_2} = \sqrt{\frac{M_2}{M_1}},
\]

where \( v_1 \) is the speed of sound in a gas of molar mass \( M_1 \) and \( v_2 \) is the speed of sound in a gas of molar mass \( M_2 \). (Hint: See Problem 91.)

94 From the knowledge that \( C_v \), the molar specific heat at constant volume, for a gas in a container is 5.0R, calculate the ratio of the speed of sound in that gas to the rms speed of the molecules, for gas temperature \( T \). (Hint: See Problem 91.)

95 The molar mass of iodine is 127 g/mol. When sound at frequency 1000 Hz is introduced to a tube of iodine gas at 400 K, an internal acoustic standing wave is set up with nodes separated by 9.57 cm. What is \( \gamma \) for the gas? (Hint: See Problem 91.)

96 For air near 0°C, by how much does the speed of sound increase for each increase in air temperature by 1°C? (Hint: See Problem 91.)

97 Two containers are at the same temperature. The gas in the first container is at pressure \( p_1 \) and has molecules with mass \( m_1 \) and root-mean-square speed \( v_{rms1} \). The gas in the second is at pressure \( 2p_1 \) and has molecules with mass \( m_2 \) and average speed \( v_{avg2} = 2v_{rms1} \). Find the ratio \( m_1/m_2 \) of the masses of their molecules.
20-1 ENTROPY

Learning Objectives

After reading this module, you should be able to . . .

20.01 Identify the second law of thermodynamics: If a process occurs in a closed system, the entropy of the system increases for irreversible processes and remains constant for reversible processes; it never decreases.

20.02 Identify that entropy is a state function (the value for a particular state of the system does not depend on how that state is reached).

20.03 Calculate the change in entropy for a process by integrating the inverse of the temperature (in kelvins) with respect to the heat \( Q \) transferred during the process.

20.04 For a phase change with a constant temperature process, apply the relationship between the entropy change \( \Delta S \), the total transferred heat \( Q \), and the temperature \( T \) (in kelvins).

20.05 For a temperature change \( \Delta T \) that is small relative to the temperature \( T \), apply the relationship between the entropy change \( \Delta S \), the transferred heat \( Q \), and the average temperature \( T_{\text{avg}} \) (in kelvins).

20.06 For an ideal gas, apply the relationship between the entropy change \( \Delta S \) and the initial and final values of the pressure and volume.

20.07 Identify that if a process is an irreversible one, the integration for the entropy change must be done for a reversible process that takes the system between the same initial and final states as the irreversible process.

20.08 For stretched rubber, relate the elastic force to the rate at which the rubber’s entropy changes with the change in the stretching distance.

Key Ideas

- An irreversible process is one that cannot be reversed by means of small changes in the environment. The direction in which an irreversible process proceeds is set by the change in entropy \( \Delta S \) of the system undergoing the process. Entropy \( S \) is a state property (or state function) of the system; that is, it depends only on the state of the system and not on the way in which the system reached that state. The entropy postulate states (in part): If an irreversible process occurs in a closed system, the entropy of the system always increases.

- The entropy change \( \Delta S \) for an irreversible process that takes a system from an initial state \( i \) to a final state \( f \) is exactly equal to the entropy change \( \Delta S \) for any reversible process that takes the system between those same two states. We can compute the latter (but not the former) with

\[
\Delta S = S_f - S_i = \int_{i}^{f} \frac{dQ}{T}.
\]

Here \( Q \) is the energy transferred as heat to or from the system during the process, and \( T \) is the temperature of the system in kelvins during the process.

- For a reversible isothermal process, the expression for an entropy change reduces to

\[
\Delta S = S_f - S_i = \frac{Q}{T}.
\]

- When the temperature change \( \Delta T \) of a system is small relative to the temperature (in kelvins) before and after the process, the entropy change can be approximated as

\[
\Delta S = S_f - S_i \approx \frac{Q}{T_{\text{avg}}},
\]

where \( T_{\text{avg}} \) is the system’s average temperature during the process.

- When an ideal gas changes reversibly from an initial state with temperature \( T_i \) and volume \( V_i \) to a final state with temperature \( T_f \) and volume \( V_f \), the change \( \Delta S \) in the entropy of the gas is

\[
\Delta S = S_f - S_i = nR \ln \frac{V_f}{V_i} + nC_v \ln \frac{T_f}{T_i}.
\]

- The second law of thermodynamics, which is an extension of the entropy postulate, states: If a process occurs in a closed system, the entropy of the system increases for irreversible processes and remains constant for reversible processes. It never decreases. In equation form,

\[
\Delta S \geq 0.
\]
What Is Physics?

Time has direction, the direction in which we age. We are accustomed to many one-way processes—that is, processes that can occur only in a certain sequence (the right way) and never in the reverse sequence (the wrong way). An egg is dropped onto a floor, a pizza is baked, a car is driven into a lamppost, large waves erode a sandy beach—these one-way processes are irreversible, meaning that they cannot be reversed by means of only small changes in their environment.

One goal of physics is to understand why time has direction and why one-way processes are irreversible. Although this physics might seem disconnected from the practical issues of everyday life, it is in fact at the heart of any engine, such as a car engine, because it determines how well an engine can run.

The key to understanding why one-way processes cannot be reversed involves a quantity known as entropy.

Irreversible Processes and Entropy

The one-way character of irreversible processes is so pervasive that we take it for granted. If these processes were to occur spontaneously (on their own) in the wrong way, we would be astonished. Yet none of these wrong-way events would violate the law of conservation of energy.

For example, if you were to wrap your hands around a cup of hot coffee, you would be astonished if your hands got cooler and the cup got warmer. That is obviously the wrong way for the energy transfer, but the total energy of the closed system (hands + cup of coffee) would be the same as the total energy if the process had run in the right way. For another example, if you popped a helium balloon, you would be astonished if, later, all the helium molecules were to gather together in the original shape of the balloon. That is obviously the wrong way for molecules to spread, but the total energy of the closed system (molecules + room) would be the same as for the right way.

Thus, changes in energy within a closed system do not set the direction of irreversible processes. Rather, that direction is set by another property that we shall discuss in this chapter—the change in entropy ΔS of the system. The change in entropy of a system is defined later in this module, but we can here state its central property, often called the entropy postulate:

If an irreversible process occurs in a closed system, the entropy S of the system always increases; it never decreases.

Entropy differs from energy in that entropy does not obey a conservation law. The energy of a closed system is conserved; it always remains constant. For irreversible processes, the entropy of a closed system always increases. Because of this property, the change in entropy is sometimes called “the arrow of time.” For example, we associate the explosion of a popcorn kernel with the forward direction of time and with an increase in entropy. The backward direction of time (a videotape run backwards) would correspond to the exploded popcorn reforming the original kernel. Because this backward process would result in an entropy decrease, it never happens.

There are two equivalent ways to define the change in entropy of a system: (1) in terms of the system’s temperature and the energy the system gains or loses as heat, and (2) by counting the ways in which the atoms or molecules that make up the system can be arranged. We use the first approach in this module and the second in Module 20-4.
Change in Entropy

Let’s approach this definition of change in entropy by looking again at a process that we described in Modules 18-5 and 19-9: the free expansion of an ideal gas. Figure 20-1a shows the gas in its initial equilibrium state \( i \), confined by a closed stopcock to the left half of a thermally insulated container. If we open the stopcock, the gas rushes to fill the entire container, eventually reaching the final equilibrium state \( f \) shown in Fig. 20-1b. This is an irreversible process; all the molecules of the gas will never return to the left half of the container.

The \( p-V \) plot of the process, in Fig. 20-2, shows the pressure and volume of the gas in its initial state \( i \) and final state \( f \). Pressure and volume are state properties, properties that depend only on the state of the gas and not on how it reached that state. Other state properties are temperature and energy. We now assume that the gas has still another state property—its entropy. Furthermore, we define the change in entropy \( S_f - S_i \) of a system during a process that takes the system from an initial state \( i \) to a final state \( f \) as

\[
\Delta S = S_f - S_i = \int_i^f \frac{dQ}{T} \quad \text{(change in entropy defined).} \tag{20-1}
\]

Here \( Q \) is the energy transferred as heat to or from the system during the process, and \( T \) is the temperature of the system in kelvins. Thus, an entropy change depends not only on the energy transferred as heat but also on the temperature at which the transfer takes place. Because \( T \) is always positive, the sign of \( \Delta S \) is the same as that of \( Q \). We see from Eq. 20-1 that the SI unit for entropy and entropy change is the joule per kelvin.

There is a problem, however, in applying Eq. 20-1 to the free expansion of Fig. 20-1. As the gas rushes to fill the entire container, the pressure, temperature, and volume of the gas fluctuate unpredictably. In other words, they do not have a sequence of well-defined equilibrium values during the intermediate stages of the change from initial state \( i \) to final state \( f \). Thus, we cannot trace a pressure–volume path for the free expansion on the \( p-V \) plot of Fig. 20-2, and we cannot find a relation between \( Q \) and \( T \) that allows us to integrate as Eq. 20-1 requires.

However, if entropy is truly a state property, the difference in entropy between states \( i \) and \( f \) must depend only on those states and not at all on the way the system went from one state to the other. Suppose, then, that we replace the irreversible free expansion of Fig. 20-1 with a reversible process that connects states \( i \) and \( f \). With a reversible process we can trace a pressure–volume path on a \( p-V \) plot, and we can find a relation between \( Q \) and \( T \) that allows us to use Eq. 20-1 to obtain the entropy change.

We saw in Module 19-9 that the temperature of an ideal gas does not change during a free expansion: \( T_i = T_f = T \). Thus, points \( i \) and \( f \) in Fig. 20-2 must be on the same isotherm. A convenient replacement process is then a reversible isothermal expansion from state \( i \) to state \( f \), which actually proceeds along that isotherm. Furthermore, because \( T \) is constant throughout a reversible isothermal expansion, the integral of Eq. 20-1 is greatly simplified.

Figure 20-3 shows how to produce such a reversible isothermal expansion. We confine the gas to an insulated cylinder that rests on a thermal reservoir maintained at the temperature \( T \). We begin by placing just enough lead shot on the movable piston so that the pressure and volume of the gas are those of the initial state \( i \) of Fig. 20-1a. We then remove shot slowly (piece by piece) until the pressure and volume of the gas are those of the final state \( f \) of Fig. 20-1b. The temperature of the gas does not change because the gas remains in thermal contact with the reservoir throughout the process.

The reversible isothermal expansion of Fig. 20-3 is physically quite different from the irreversible free expansion of Fig. 20-1. However, both processes have the same initial state and the same final state and thus must have the same change in entropy.
Because we removed the lead shot slowly, the intermediate states of the gas are equilibrium states, so we can plot them on a $p$-$V$ diagram (Fig. 20-4).

To apply Eq. 20-1 to the isothermal expansion, we take the constant temperature $T$ outside the integral, obtaining

$$\Delta S = S_f - S_i = \frac{1}{T} \int f dQ.$$  \hspace{1cm} (20-1)

Because $\int dQ = Q$, where $Q$ is the total energy transferred as heat during the process, we have

$$\Delta S = S_f - S_i = \frac{Q}{T} \quad \text{(change in entropy, isothermal process)}. \hspace{1cm} (20-2)$$

To keep the temperature $T$ of the gas constant during the isothermal expansion of Fig. 20-3, heat $Q$ must have been energy transferred from the reservoir to the gas. Thus, $Q$ is positive and the entropy of the gas increases during the isothermal process and during the free expansion of Fig. 20-1.

To summarize:

**To find the entropy change for an irreversible process, replace that process with any reversible process that connects the same initial and final states. Calculate the entropy change for this reversible process with Eq. 20-1.**

When the temperature change $\Delta T$ of a system is small relative to the temperature (in kelvins) before and after the process, the entropy change can be approximated as

$$\Delta S = S_f - S_i = \frac{Q}{T_{avg}},$$  \hspace{1cm} (20-3)

where $T_{avg}$ is the average temperature of the system in kelvins during the process.

**Checkpoint 1**

Water is heated on a stove. Rank the entropy changes of the water as its temperature rises (a) from 20°C to 30°C, (b) from 30°C to 35°C, and (c) from 80°C to 85°C, greatest first.

**Entropy as a State Function**

We have assumed that entropy, like pressure, energy, and temperature, is a property of the state of a system and is independent of how that state is reached. That entropy is indeed a state function (as state properties are usually called) can be deduced only by experiment. However, we can prove it is a state function for the special and important case in which an ideal gas is taken through a reversible process.

To make the process reversible, it is done slowly in a series of small steps, with the gas in an equilibrium state at the end of each step. For each small step, the energy transferred as heat to or from the gas is $dQ$, the work done by the gas is $dW$, and the change in internal energy is $dE_{int}$. These are related by the first law of thermodynamics in differential form (Eq. 18-27):

$$dE_{int} = dQ - dW.$$  \hspace{1cm} (18-27)

Because the steps are reversible, with the gas in equilibrium states, we can use Eq. 18-24 to replace $dW$ with $p \, dV$ and Eq. 19-45 to replace $dE_{int}$ with $nC_v \, dT$. Solving for $dQ$ then leads to

$$dQ = p \, dV + nC_v \, dT.$$  \hspace{1cm} (18-24)

Using the ideal gas law, we replace $p$ in this equation with $nRT/V$. Then we divide each term in the resulting equation by $T$, obtaining

$$\frac{dQ}{T} = nR \frac{dV}{V} + nC_v \frac{dT}{T}.$$
Now let us integrate each term of this equation between an arbitrary initial state $i$ and an arbitrary final state $f$ to get

$$\int_i^f \frac{dQ}{T} = \int_i^f nR \frac{dV}{V} + \int_i^f nC_v \frac{dT}{T}. $$

The quantity on the left is the entropy change $\Delta S$ ($= S_f - S_i$) defined by Eq. 20-1. Substituting this and integrating the quantities on the right yield

$$\Delta S = S_f - S_i = nR \ln \frac{V_f}{V_i} + nC_v \ln \frac{T_f}{T_i}. \quad (20-4)$$

Note that we did not have to specify a particular reversible process when we integrated. Therefore, the integration must hold for all reversible processes that take the gas from state $i$ to state $f$. Thus, the change in entropy $\Delta S$ between the initial and final states of an ideal gas depends only on properties of the initial state ($V_i$ and $T_i$) and properties of the final state ($V_f$ and $T_f$); $\Delta S$ does not depend on how the gas changes between the two states.

**Checkpoint 2**

An ideal gas has temperature $T_1$ at the initial state $i$ shown in the $p$-$V$ diagram here. The gas has a higher temperature $T_2$ at final states $a$ and $b$, which it can reach along the paths shown. Is the entropy change along the path to state $a$ larger than, smaller than, or the same as that along the path to state $b$?

**Sample Problem 20.01  Entropy change of two blocks coming to thermal equilibrium**

Figure 20-5a shows two identical copper blocks of mass $m = 1.5 \text{ kg}$: block $L$ at temperature $T_{iL} = 60^\circ \text{C}$ and block $R$ at temperature $T_{iR} = 20^\circ \text{C}$. The blocks are in a thermally insulated box and are separated by an insulating shutter. When we lift the shutter, the blocks eventually come to the equilibrium temperature $T_f = 40^\circ \text{C}$ (Fig. 20-5b). What is the net entropy change of the two-block system during this irreversible process? The specific heat of copper is $386 \text{ J/kg} \cdot \text{K}$.

**KEY IDEA**

To calculate the entropy change, we must find a reversible process that takes the system from the initial state of Fig. 20-5a to the final state of Fig. 20-5b. We can calculate the net entropy change $\Delta S_{rev}$ of the reversible process using Eq. 20-1, and then the entropy change for the irreversible process is equal to $\Delta S_{rev}$.

**Calculations:** For the reversible process, we need a thermal reservoir whose temperature can be changed slowly (say, by turning a knob). We then take the blocks through the following two steps, illustrated in Fig. 20-6.

**Step 1:** With the reservoir’s temperature set at $60^\circ \text{C}$, put block $L$ on the reservoir. (Since block and reservoir are at the same temperature, they are already in thermal equilib-
and the block to 40°C. As the block’s temperature changes by each increment \(dT\) during this process, energy \(dQ\) is transferred as heat from the block to the reservoir. Using Eq. 18-14, we can write this transferred energy as \(dQ = mc\,dT\), where \(c\) is the specific heat of copper. According to Eq. 20-1, the entropy change \(\Delta S_L\) of block \(L\) during the full temperature change from initial temperature \(T_{iL}\) (= 60°C = 333 K) to final temperature \(T_f\) (= 40°C = 313 K) is

\[
\Delta S_L = \int_{iL}^{f} \frac{dQ}{T} = \int_{iL}^{f} \frac{mc\,dT}{T} = mc \int_{iL}^{f} \frac{dT}{T}.
\]

Inserting the given data yields

\[
\Delta S_L = (1.5 \text{ kg})(386 \text{ J/kg} \cdot \text{K}) \ln \frac{313 \text{ K}}{333 \text{ K}} = -35.86 \text{ J/K}.
\]

**Step 2:** With the reservoir’s temperature now set at 20°C, put block \(R\) on the reservoir. Then slowly raise the temperature of the reservoir and the block to 40°C. With the same reasoning used to find \(\Delta S_L\), you can show that the entropy change \(\Delta S_R\) of block \(R\) during this process is

\[
\Delta S_R = (1.5 \text{ kg})(386 \text{ J/kg} \cdot \text{K}) \ln \frac{313 \text{ K}}{293 \text{ K}} = +38.23 \text{ J/K}.
\]

The net entropy change \(\Delta S_{\text{rev}}\) of the two-block system undergoing this two-step reversible process is then

\[
\Delta S_{\text{rev}} = \Delta S_L + \Delta S_R = -35.86 \text{ J/K} + 38.23 \text{ J/K} = 2.4 \text{ J/K}.
\]

Thus, the net entropy change \(\Delta S_{\text{irrev}}\) for the two-block system undergoing the actual irreversible process is

\[
\Delta S_{\text{irrev}} = \Delta S_{\text{rev}} = 2.4 \text{ J/K}.
\]

This result is positive, in accordance with the entropy postulate.

### Sample Problem 20.02 Entropy change of a free expansion of a gas

Suppose 1.0 mol of nitrogen gas is confined to the left side of the container of Fig. 20-1a. You open the stopcock, and the volume of the gas doubles. What is the entropy change of the gas for this irreversible process? Treat the gas as ideal.

**KEY IDEAS**

1. We can determine the entropy change for the reversible process by calculating it for a reversible process that provides the same change in volume.
2. The temperature of the gas does not change in the free expansion. Thus, the reversible process should be an isothermal expansion — namely, the one of Figs. 20-3 and 20-4.

**Calculations:** From Table 19-4, the energy \(Q\) added as heat to the gas as it expands isothermally at temperature \(T\) from an initial volume \(V_i\) to a final volume \(V_f\) is

\[
Q = nRT \ln \frac{V_f}{V_i},
\]

in which \(n\) is the number of moles of gas present. From Eq. 20-2 the entropy change for this reversible process in which the temperature is held constant is

\[
\Delta S_{\text{rev}} = \frac{Q}{T} = \frac{nRT \ln(V_f/V_i)}{T} = nR \ln \frac{V_f}{V_i}.
\]

Substituting \(n = 1.00 \text{ mol}\) and \(V_f/V_i = 2\), we find

\[
\Delta S_{\text{rev}} = nR \ln \frac{V_f}{V_i} = (1.00 \text{ mol})(8.31 \text{ J/mol} \cdot \text{K})(\ln 2)
\]

\[
= +5.76 \text{ J/K}.
\]

Thus, the entropy change for the free expansion (and for all other processes that connect the initial and final states shown in Fig. 20-2) is

\[
\Delta S_{\text{irrev}} = \Delta S_{\text{rev}} = +5.76 \text{ J/K}.
\]

Because \(\Delta S\) is positive, the entropy increases, in accordance with the entropy postulate.

---

**The Second Law of Thermodynamics**

Here is a puzzle. In the process of going from (a) to (b) in Fig. 20-3, the entropy change of the gas (our system) is positive. However, because the process is reversible, we can also go from (b) to (a) by, say, gradually adding lead shot to the piston, to restore the initial gas volume. To maintain a constant temperature, we need to remove energy as heat, but that means \(Q\) is negative and thus the entropy change is also. Doesn’t this entropy decrease violate the entropy postulate: en-
entropy always increases? No, because the postulate holds only for irreversible processes in closed systems. Here, the process is not irreversible and the system is not closed (because of the energy transferred to and from the reservoir as heat).

However, if we include the reservoir, along with the gas, as part of the system, then we do have a closed system. Let’s check the change in entropy of the enlarged system gas + reservoir for the process that takes it from (b) to (a) in Fig. 20-3. During this reversible process, energy is transferred as heat from the gas to the reservoir—that is, from one part of the enlarged system to another. Let |Q| represent the absolute value (or magnitude) of this heat. With Eq. 20-2, we can then calculate separately the entropy changes for the gas (which loses |Q|) and the reservoir (which gains |Q|). We get

\[
\Delta S_{\text{gas}} = -\frac{|Q|}{T}
\]

and

\[
\Delta S_{\text{res}} = +\frac{|Q|}{T}.
\]

The entropy change of the closed system is the sum of these two quantities: 0.

With this result, we can modify the entropy postulate to include both reversible and irreversible processes:

\[
\Delta S \geq 0 \quad \text{(second law of thermodynamics)},
\]

where the greater-than sign applies to irreversible processes and the equals sign to reversible processes. Equation 20-5 applies only to closed systems.

In the real world almost all processes are irreversible to some extent because of friction, turbulence, and other factors, so the entropy of real closed systems undergoing real processes always increases. Processes in which the system’s entropy remains constant are always idealizations.

Force Due to Entropy

To understand why rubber resists being stretched, let’s write the first law of thermodynamics

\[
dE = dQ - dW
\]

for a rubber band undergoing a small increase in length \(dx\) as we stretch it between our hands. The force from the rubber band has magnitude \(F\), is directed inward, and does work \(dW = -F \, dx\) during length increase \(dx\). From Eq. 20-2 (\(\Delta S = Q/T\)), small changes in \(Q\) and \(S\) at constant temperature are related by \(dS = dQ/T\), or \(dQ = T \, dS\). So, now we can rewrite the first law as

\[
dE = T \, dS + F \, dx.
\]

To good approximation, the change \(dE\) in the internal energy of rubber is 0 if the total stretch of the rubber band is not very much. Substituting 0 for \(dE\) in Eq. 20-6 leads us to an expression for the force from the rubber band:

\[
F = -T \cdot \frac{dS}{dx}.
\]
20.2 ENTROPY IN THE REAL WORLD: ENGINES

Learning Objectives

After reading this module, you should be able to . . .

20.09 Identify that a heat engine is a device that extracts energy from its environment in the form of heat and does useful work and that in an ideal heat engine, all processes are reversible, with no wasteful energy transfers.

20.10 Sketch a p-V diagram for the cycle of a Carnot engine, indicating the direction of cycling, the nature of the processes involved, the work done during each process (including algebraic sign), the net work done in the cycle, and the heat transferred during each process (including algebraic sign).

20.11 Sketch a Carnot cycle on a temperature–entropy diagram, indicating the heat transfers.

20.12 Determine the net entropy change around a Carnot cycle.

20.13 Calculate the efficiency \( \varepsilon_c \) of a Carnot engine in terms of the heat transfers and also in terms of the temperatures of the reservoirs.

20.14 Identify that there are no perfect engines in which the energy transferred as heat \( Q \) from a high temperature reservoir goes entirely into the work \( W \) done by the engine.

20.15 Sketch a p-V diagram for the cycle of a Stirling engine, indicating the direction of cycling, the nature of the processes involved, the work done during each process (including algebraic sign), the net work done in the cycle, and the heat transfers during each process.

Key Ideas

- An engine is a device that, operating in a cycle, extracts energy as heat \( |Q_H| \) from a high-temperature reservoir and does a certain amount of work \( |W| \). The efficiency \( \varepsilon \) of any engine is defined as

  \[
  \varepsilon = \frac{\text{energy we get}}{\text{energy we pay for}} = \frac{|W|}{|Q_H|}.
  \]

- In an ideal engine, all processes are reversible and no wasteful energy transfers occur due to, say, friction and turbulence.

- A Carnot engine is an ideal engine that follows the cycle of Fig. 20-9. Its efficiency is

  \[
  \varepsilon_c = 1 - \frac{|Q_L|}{|Q_H|} = 1 - \frac{T_L}{T_H}.
  \]

in which \( T_H \) and \( T_L \) are the temperatures of the high- and low-temperature reservoirs, respectively. Real engines always have an efficiency lower than that of a Carnot engine. Ideal engines that are not Carnot engines also have efficiencies lower than that of a Carnot engine.

- A perfect engine is an imaginary engine in which energy extracted as heat from the high-temperature reservoir is converted completely to work. Such an engine would violate the second law of thermodynamics, which can be restated as follows: No series of processes is possible whose sole result is the absorption of energy as heat from a thermal reservoir and the complete conversion of this energy to work.

Entropy in the Real World: Engines

A heat engine, or more simply, an engine, is a device that extracts energy from its environment in the form of heat and does useful work. At the heart of every engine is a working substance. In a steam engine, the working substance is water,
in both its vapor and its liquid form. In an automobile engine the working substance is a gasoline–air mixture. If an engine is to do work on a sustained basis, the working substance must operate in a cycle; that is, the working substance must pass through a closed series of thermodynamic processes, called strokes, returning again and again to each state in its cycle. Let us see what the laws of thermodynamics can tell us about the operation of engines.

A Carnot Engine

We have seen that we can learn much about real gases by analyzing an ideal gas, which obeys the simple law \( pV = nRT \). Although an ideal gas does not exist, any real gas approaches ideal behavior if its density is low enough. Similarly, we can study real engines by analyzing the behavior of an ideal engine.

In an ideal engine, all processes are reversible and no wasteful energy transfers occur due to, say, friction and turbulence.

We shall focus on a particular ideal engine called a Carnot engine after the French scientist and engineer N. L. Sadi Carnot (pronounced “car-no”), who first proposed the engine’s concept in 1824. This ideal engine turns out to be the best (in principle) at using energy as heat to do useful work. Surprisingly, Carnot was able to analyze the performance of this engine before the first law of thermodynamics and the concept of entropy had been discovered.

Figure 20-8 shows schematically the operation of a Carnot engine. During each cycle of the engine, the working substance absorbs energy \( Q_H \) as heat from a thermal reservoir at constant temperature \( T_H \) and discharges energy \( Q_L \) as heat to a second thermal reservoir at a constant lower temperature \( T_L \).

Figure 20-9 shows a \( p-V \) plot of the Carnot cycle—the cycle followed by the working substance. As indicated by the arrows, the cycle is traversed in the clockwise direction. Imagine the working substance to be a gas, confined to an insulating cylinder with a weighted, movable piston. The cylinder may be placed at will on either of the two thermal reservoirs, as in Fig. 20-6, or on an insulating slab. Figure 20-9a shows that, if we place the cylinder in contact with the high-temperature reservoir at temperature \( T_H \), heat \( Q_H \) is transferred to the working substance from this reservoir as the gas undergoes an isothermal expansion from volume \( V_a \) to volume \( V_b \). Similarly, with the working substance in contact with the low-temperature reservoir at temperature \( T_L \), heat \( Q_L \) is transferred from
the working substance to the low-temperature reservoir as the gas undergoes an isothermal compression from volume \( V_a \) to volume \( V_d \) (Fig. 20-9).

In the engine of Fig. 20-8, we assume that heat transfers to or from the working substance can take place only during the isothermal processes \( ab \) and \( cd \) of Fig. 20-9. Therefore, processes \( bc \) and \( da \) in that figure, which connect the two isotherms at temperatures \( T_H \) and \( T_L \), must be (reversible) adiabatic processes; that is, they must be processes in which no energy is transferred as heat. To ensure this, during processes \( bc \) and \( da \) the cylinder is placed on an insulating slab as the volume of the working substance is changed.

During the processes \( ab \) and \( bc \) of Fig. 20-9a, the working substance is expanding and thus doing positive work as it raises the weighted piston. This work is represented by the area under curve \( abc \). During the processes \( cd \) and \( da \) (Fig. 20-9b), the working substance is being compressed, which means that it is doing negative work on its environment or, equivalently, that its environment is doing work on it as the loaded piston descends. This work is represented by the area under curve \( cda \). The net work per cycle, which is represented by \( W \) in both Figs. 20-8 and 20-9, is the difference between these two areas and is a positive quantity equal to the area enclosed by cycle \( abcd \) in Fig. 20-9. This work \( W \) is performed on some outside object, such as a load to be lifted.

Equation 20-1 (\( \Delta S = \int \frac{dQ}{T} \)) tells us that any energy transfer as heat must involve a change in entropy. To see this for a Carnot engine, we can plot the Carnot cycle on a temperature–entropy (T-S) diagram as in Fig. 20-10. The lettered points \( a \), \( b \), \( c \), and \( d \) there correspond to the lettered points in the \( p-V \) diagram in Fig. 20-9. The two horizontal lines in Fig. 20-10 correspond to the two isothermal processes of the cycle. Process \( ab \) is the isothermal expansion of the cycle. As the working substance (reversibly) absorbs energy \( |Q_H| \) as heat at constant temperature \( T_H \) during the expansion, its entropy increases. Similarly, during the isothermal compression \( cd \), the working substance (reversibly) loses energy \( |Q_L| \) as heat at constant temperature \( T_L \), and its entropy decreases.

The two vertical lines in Fig. 20-10 correspond to the two adiabatic processes of the Carnot cycle. Because no energy is transferred as heat during the two processes, the entropy of the working substance is constant during them.

**The Work** To calculate the net work done by a Carnot engine during a cycle, let us apply Eq. 18-26, the first law of thermodynamics (\( \Delta E_{\text{int}} = Q - W \)), to the working substance. That substance must return again and again to any arbitrarily selected state in the cycle. Thus, if \( X \) represents any state property of the working substance, such as pressure, temperature, volume, internal energy, or entropy, we must have \( \Delta X = 0 \) for every cycle. It follows that \( \Delta E_{\text{int}} = 0 \) for a complete cycle of the working substance. Recalling that \( Q \) in Eq. 18-26 is the net heat transfer per cycle and \( W \) is the net work, we can write the first law of thermodynamics for the Carnot cycle as

\[
W = |Q_H| - |Q_L|. \tag{20-8}
\]

**Entropy Changes** In a Carnot engine, there are two (and only two) reversible energy transfers as heat, and thus two changes in the entropy of the working substance—one at temperature \( T_H \) and one at \( T_L \). The net entropy change per cycle is then

\[
\Delta S = \Delta S_H + \Delta S_L = \frac{|Q_H|}{T_H} - \frac{|Q_L|}{T_L}. \tag{20-9}
\]

Here \( \Delta S_H \) is positive because energy \( |Q_H| \) is added to the working substance as heat (an increase in entropy) and \( \Delta S_L \) is negative because energy \( |Q_L| \) is removed from the working substance as heat (a decrease in entropy). Because entropy is a state function, we must have \( \Delta S = 0 \) for a complete cycle. Putting \( \Delta S = 0 \) in Eq. 20-9 requires that

\[
\frac{|Q_H|}{T_H} = \frac{|Q_L|}{T_L}. \tag{20-10}
\]

Note that, because \( T_H > T_L \), we must have \( |Q_H| > |Q_L| \); that is, more energy is
extracted as heat from the high-temperature reservoir than is delivered to the low-temperature reservoir.

We shall now derive an expression for the efficiency of a Carnot engine.

**Efficiency of a Carnot Engine**

The purpose of any engine is to transform as much of the extracted energy $Q_H$ into work as possible. We measure its success in doing so by its **thermal efficiency** $\varepsilon$, defined as the work the engine does per cycle (“energy we get”) divided by the energy it absorbs as heat per cycle (“energy we pay for”):

$$\varepsilon = \frac{\text{energy we get}}{\text{energy we pay for}} = \frac{|W|}{|Q_H|} \quad (\text{efficiency, any engine}). \quad (20-11)$$

For a Carnot engine we can substitute for $W$ from Eq. 20-8 to write Eq. 20-11 as

$$\varepsilon_C = \frac{|Q_H| - |Q_L|}{Q_H} = 1 - \frac{|Q_L|}{|Q_H|}. \quad (20-12)$$

Using Eq. 20-10 we can write this as

$$\varepsilon_C = 1 - \frac{T_L}{T_H} \quad (\text{efficiency, Carnot engine}), \quad (20-13)$$

where the temperatures $T_L$ and $T_H$ are in kelvins. Because $T_L < T_H$, the Carnot engine necessarily has a thermal efficiency less than unity—that is, less than 100%. This is indicated in Fig. 20-8, which shows that only part of the energy extracted as heat from the high-temperature reservoir is available to do work, and the rest is delivered to the low-temperature reservoir. We shall show in Module 20-3 that no real engine can have a thermal efficiency greater than that calculated from Eq. 20-13.

Inventors continually try to improve engine efficiency by reducing the energy $|Q_L|$ that is “thrown away” during each cycle. The inventor’s dream is to produce the **perfect engine**, diagrammed in Fig. 20-11, in which $|Q_L|$ is reduced to zero and $|Q_H|$ is converted completely into work. Such an engine on an ocean liner, for example, could extract energy as heat from the water and use it to drive the propellers, with no fuel cost. An automobile fitted with such an engine could extract energy as heat from the surrounding air and use it to drive the car, again with no fuel cost. Alas, a perfect engine is only a dream: Inspection of Eq. 20-13 shows that we can achieve 100% engine efficiency (that is, $\varepsilon = 1$) only if $T_L = 0$ or $T_H \rightarrow \infty$, impossible requirements. Instead, experience gives the following alternative version of the second law of thermodynamics, which says in short, there are no perfect engines:

No series of processes is possible whose sole result is the transfer of energy as heat from a thermal reservoir and the complete conversion of this energy to work.

To summarize: The thermal efficiency given by Eq. 20-13 applies only to Carnot engines. Real engines, in which the processes that form the engine cycle are not reversible, have lower efficiencies. If your car were powered by a Carnot engine, it would have an efficiency of about 55% according to Eq. 20-13; its actual efficiency is probably about 25%. A nuclear power plant (Fig. 20-12), taken in its entirety, is an engine. It extracts energy as heat from a reactor core, does work by means of a turbine, and discharges energy as heat to a nearby river. If the power plant operated as a Carnot engine, its efficiency would be about 40%; its actual efficiency is about 30%. In designing engines of any type, there is simply no way to beat the efficiency limitation imposed by Eq. 20-13.
Figure 20-13  A $p$-$V$ plot for the working substance of an ideal Stirling engine, with the working substance assumed for convenience to be an ideal gas.

Stirling Engine

Equation 20-13 applies not to all ideal engines but only to those that can be represented as in Fig. 20-9—that is, to Carnot engines. For example, Fig. 20-13 shows the operating cycle of an ideal Stirling engine. Comparison with the Carnot cycle of Fig. 20-9 shows that each engine has isothermal heat transfers at temperatures $T_\text{H}$ and $T_\text{L}$. However, the two isotherms of the Stirling engine cycle are connected, not by adiabatic processes as for the Carnot engine but by constant-volume processes. To increase the temperature of a gas at constant volume reversibly from $T_\text{L}$ to $T_\text{H}$ (process $da$ of Fig. 20-13) requires a transfer of energy as heat to the working substance from a thermal reservoir whose temperature can be varied smoothly between those limits. Also, a reverse transfer is required in process $bc$. Thus, reversible heat transfers (and corresponding entropy changes) occur in all four of the processes that form the cycle of a Stirling engine, not just two processes as in a Carnot engine. Thus, the derivation that led to Eq. 20-13 does not apply to an ideal Stirling engine. More important, the efficiency of an ideal Stirling engine is lower than that of a Carnot engine operating between the same two temperatures. Real Stirling engines have even lower efficiencies.

The Stirling engine was developed in 1816 by Robert Stirling. This engine, long neglected, is now being developed for use in automobiles and spacecraft. A Stirling engine delivering 5000 hp (3.7 MW) has been built. Because they are quiet, Stirling engines are used on some military submarines.

Three Carnot engines operate between reservoir temperatures of (a) 400 and 500 K, (b) 600 and 800 K, and (c) 400 and 600 K. Rank the engines according to their thermal efficiencies, greatest first.

Sample Problem 20.03  Carnot engine, efficiency, power, entropy changes

Imagine a Carnot engine that operates between the temperatures $T_\text{H} = 850$ K and $T_\text{L} = 300$ K. The engine performs 1200 J of work each cycle, which takes 0.25 s.

(a) What is the efficiency of this engine?

**KEY IDEA**

The efficiency $\varepsilon$ of a Carnot engine depends only on the ratio $T_\text{L}/T_\text{H}$ of the temperatures (in kelvins) of the thermal reservoirs to which it is connected.

**Calculation:** Thus, from Eq. 20-13, we have

$$\varepsilon = 1 - \frac{T_\text{L}}{T_\text{H}} = 1 - \frac{300 \text{ K}}{850 \text{ K}} = 0.647 \approx 65\%.$$  \hspace{1cm} (Answer)

(b) What is the average power of this engine?

**KEY IDEA**

The average power $P$ of an engine is the ratio of the work $W$ it does per cycle to the time $t$ that each cycle takes.

**Calculation:** For this Carnot engine, we find

$$P = \frac{W}{t} = \frac{1200 \text{ J}}{0.25 \text{ s}} = 4800 \text{ W} = 4.8 \text{ kW}.$$  \hspace{1cm} (Answer)

(c) How much energy $|Q_\text{H}|$ is extracted as heat from the high-temperature reservoir every cycle?

**KEY IDEA**

The efficiency $\varepsilon$ is the ratio of the work $W$ that is done per cycle to the energy $|Q_\text{H}|$ that is extracted as heat from the high-temperature reservoir per cycle ($\varepsilon = W/|Q_\text{H}|$).

**Calculation:** Here we have

$$|Q_\text{H}| = \frac{W}{\varepsilon} = \frac{1200 \text{ J}}{0.647} = 1855 \text{ J}.$$  \hspace{1cm} (Answer)

(d) How much energy $|Q_\text{L}|$ is delivered as heat to the low-temperature reservoir every cycle?

**KEY IDEA**

For a Carnot engine, the work $W$ done per cycle is equal to the difference in the energy transfers as heat: $|Q_\text{H}| - |Q_\text{L}|$, as in Eq. 20-8.

**Calculation:** Thus, we have

$$|Q_\text{L}| = |Q_\text{H}| - W = 1855 \text{ J} - 1200 \text{ J} = 655 \text{ J}.$$  \hspace{1cm} (Answer)
(e) By how much does the entropy of the working substance change as a result of the energy transferred to it from the high-temperature reservoir? From it to the low-temperature reservoir?

**KEY IDEA**

The entropy change $\Delta S$ during a transfer of energy as heat $Q$ at constant temperature $T$ is given by Eq. 20-2 ($\Delta S = Q/T$).

**Calculations:** Thus, for the positive transfer of energy $Q_H$ from the high-temperature reservoir at $T_H$, the change in the entropy of the working substance is

$$\Delta S_H = \frac{Q_H}{T_H} = \frac{1855 \text{ J}}{850 \text{ K}} = +2.18 \text{ J/K.} \quad \text{(Answer)}$$

Similarly, for the negative transfer of energy $Q_L$ to the low-temperature reservoir at $T_L$, we have

$$\Delta S_L = \frac{Q_L}{T_L} = \frac{-655 \text{ J}}{300 \text{ K}} = -2.18 \text{ J/K.} \quad \text{(Answer)}$$

Note that the net entropy change of the working substance for one cycle is zero, as we discussed in deriving Eq. 20-10.

---

**Sample Problem 20.04 Impossibly efficient engine**

An inventor claims to have constructed an engine that has an efficiency of 75% when operated between the boiling and freezing points of water. Is this possible?

**KEY IDEA**

The efficiency of a real engine must be less than the efficiency of a Carnot engine operating between the same two temperatures.

---

20-3 REFRIGERATORS AND REAL ENGINES

**Learning Objectives**

*After reading this module, you should be able to . . .*

20.16 Identify that a refrigerator is a device that uses work to transfer energy from a low-temperature reservoir to a high-temperature reservoir, and that an ideal refrigerator is one that does this with reversible processes and no wasteful losses.

20.17 Sketch a $p-V$ diagram for the cycle of a Carnot refrigerator, indicating the direction of cycling, the nature of the processes involved, the work done during each process (including algebraic sign), the net work done in the cycle, and the heat transferred during each process (including algebraic sign).

20.18 Apply the relationship between the coefficient of performance $K$ and the heat exchanges with the reservoirs and the temperatures of the reservoirs.

20.19 Identify that there is no ideal refrigerator in which all of the energy extracted from the low-temperature reservoir is transferred to the high-temperature reservoir.

20.20 Identify that the efficiency of a real engine is less than that of the ideal Carnot engine.

**Key Ideas**

- A refrigerator is a device that, operating in a cycle, has work $W$ done on it as it extracts energy $|Q_L|$ as heat from a low-temperature reservoir. The coefficient of performance $K$ of a refrigerator is defined as

$$K = \frac{\text{what we want}}{\text{what we pay for}} = \frac{|Q_L|}{|W|}.$$

- A Carnot refrigerator is a Carnot engine operating in reverse. Its coefficient of performance is

$$K_C = \frac{|Q_L|}{|Q_H| - |Q_L|} = \frac{T_L}{T_H - T_L}.$$

- A perfect refrigerator is an entirely imaginary refrigerator in which energy extracted as heat from the low-temperature reservoir is somehow converted completely to heat discharged to the high-temperature reservoir without any need for work.

- A perfect refrigerator would violate the second law of thermodynamics, which can be restated as follows: No series of processes is possible whose sole result is the transfer of energy as heat from a reservoir at a given temperature to a reservoir at a higher temperature (without work being involved).
Entropy in the Real World: Refrigerators

A refrigerator is a device that uses work in order to transfer energy from a low-temperature reservoir to a high-temperature reservoir as the device continuously repeats a set series of thermodynamic processes. In a household refrigerator, for example, work is done by an electrical compressor to transfer energy from the food storage compartment (a low-temperature reservoir) to the room (a high-temperature reservoir).

Air conditioners and heat pumps are also refrigerators. For an air conditioner, the low-temperature reservoir is the room that is to be cooled and the high-temperature reservoir is the warmer outdoors. A heat pump is an air conditioner that can be operated in reverse to heat a room; the room is the high-temperature reservoir, and heat is transferred to it from the cooler outdoors.

Let us consider an ideal refrigerator:

In an ideal refrigerator, all processes are reversible and no wasteful energy transfers occur as a result of, say, friction and turbulence.

Figure 20-14 shows the basic elements of an ideal refrigerator. Note that its operation is the reverse of how the Carnot engine of Fig. 20-8 operates. In other words, all the energy transfers, as either heat or work, are reversed from those of a Carnot engine. We can call such an ideal refrigerator a Carnot refrigerator.

The designer of a refrigerator would like to extract as much energy from a cold reservoir to a warm reservoir without the need for work. A measure of the efficiency of a refrigerator, then, is

$$K = \frac{\text{what we want}}{\text{what we pay for}} = \frac{|Q_L|}{|W|} \quad (\text{coefficient of performance, any refrigerator}). \quad (20-14)$$

where $K$ is called the coefficient of performance. For a Carnot refrigerator, the first law of thermodynamics gives $|W| = |Q_H| - |Q_L|$, where $|Q_H|$ is the magnitude of the energy transferred as heat to the high-temperature reservoir. Equation 20-14 then becomes

$$K_C = \frac{|Q_L|}{|Q_H| - |Q_L|}. \quad (20-15)$$

Because a Carnot refrigerator is a Carnot engine operating in reverse, we can combine Eq. 20-10 with Eq. 20-15; after some algebra we find

$$K_C = \frac{T_L}{T_H - T_L} \quad (\text{coefficient of performance, Carnot refrigerator}). \quad (20-16)$$

For typical room air conditioners, $K \approx 2.5$. For household refrigerators, $K \approx 5$. Perversely, the value of $K$ is higher the closer the temperatures of the two reservoirs are to each other. That is why heat pumps are more effective in temperate climates than in very cold climates.

It would be nice to own a refrigerator that did not require some input of work—that is, one that would run without being plugged in. Figure 20-15 represents another “inventor’s dream,” a perfect refrigerator that transfers energy as heat $Q$ from a cold reservoir to a warm reservoir without the need for work. Because the unit operates in cycles, the entropy of the working substance does not change during a complete cycle. The entropies of the two reservoirs, however, do change: The entropy change for the cold reservoir is $-|Q|/T_L$, and that for the warm reservoir is $+|Q|/T_H$. Thus, the net entropy change for the entire system is

$$\Delta S = -\frac{|Q|}{T_L} + \frac{|Q|}{T_H}.$$
Because \( T_H > T_L \), the right side of this equation is negative and thus the net change in entropy per cycle for the closed system \( \text{refrigerator} + \text{reservoirs} \) is also negative. Because such a decrease in entropy violates the second law of thermodynamics (Eq. 20-5), a perfect refrigerator does not exist. (If you want your refrigerator to operate, you must plug it in.)

Here, then, is another way to state the second law of thermodynamics:

No series of processes is possible whose sole result is the transfer of energy as heat from a reservoir at a given temperature to a reservoir at a higher temperature.

In short, there are no perfect refrigerators.

**Checkpoint 4**

You wish to increase the coefficient of performance of an ideal refrigerator. You can do so by (a) running the cold chamber at a slightly higher temperature, (b) running the cold chamber at a slightly lower temperature, (c) moving the unit to a slightly warmer room, or (d) moving it to a slightly cooler room. The magnitudes of the temperature changes are to be the same in all four cases. List the changes according to the resulting coefficients of performance, greatest first.

**The Efficiencies of Real Engines**

Let \( \varepsilon_C \) be the efficiency of a Carnot engine operating between two given temperatures. Here we prove that no real engine operating between those temperatures can have an efficiency greater than \( \varepsilon_C \). If it could, the engine would violate the second law of thermodynamics.

Let us assume that an inventor, working in her garage, has constructed an engine \( X \), which she claims has an efficiency \( \varepsilon_X \) that is greater than \( \varepsilon_C \):

\[
\varepsilon_X > \varepsilon_C \quad (\text{a claim}). \tag{20-17}
\]

Let us couple engine \( X \) to a Carnot refrigerator, as in Fig. 20-16a. We adjust the strokes of the Carnot refrigerator so that the work it requires per cycle is just equal to that provided by engine \( X \). Thus, no (external) work is performed on or by the combination engine + refrigerator of Fig. 20-16a, which we take as our system.

If Eq. 20-17 is true, from the definition of efficiency (Eq. 20-11), we must have

\[
\frac{|W|}{|Q'_H|} > \frac{|W|}{|Q_H|},
\]

where the prime refers to engine \( X \) and the right side of the inequality is the efficiency of the Carnot refrigerator when it operates as an engine. This inequality requires that

\[
|Q_H| > |Q'_H|. \tag{20-18}
\]

**Figure 20-16** (a) Engine \( X \) drives a Carnot refrigerator. (b) If, as claimed, engine \( X \) is more efficient than a Carnot engine, then the combination shown in (a) is equivalent to the perfect refrigerator shown here. This violates the second law of thermodynamics, so we conclude that engine \( X \) cannot be more efficient than a Carnot engine.
Because the work done by engine $X$ is equal to the work done on the Carnot refrigerator, we have, from the first law of thermodynamics as given by Eq. 20-8,

$$|Q_{in}| - |Q_{out}| = |Q_{in}^*| - |Q_{out}^*|,$$

which we can write as

$$|Q_{in} - Q_{in}^*| = |Q_{out} - Q_{out}^*| = Q. \quad (20-19)$$

Because of Eq. 20-18, the quantity $Q$ in Eq. 20-19 must be positive.

Comparison of Eq. 20-19 with Fig. 20-16 shows that the net effect of engine $X$ and the Carnot refrigerator working in combination is to transfer energy $Q$ as heat from a low-temperature reservoir to a high-temperature reservoir without the requirement of work. Thus, the combination acts like the perfect refrigerator of Fig. 20-15, whose existence is a violation of the second law of thermodynamics.

Something must be wrong with one or more of our assumptions, and it can only be Eq. 20-17. We conclude that no real engine can have an efficiency greater than that of a Carnot engine when both engines work between the same two temperatures. At most, the real engine can have an efficiency equal to that of a Carnot engine. In that case, the real engine is a Carnot engine.

---

### 20-4 A Statistical View of Entropy

#### Learning Objectives

After reading this module, you should be able to . . .

- Explain what is meant by the configurations of a system of molecules.
- Calculate the multiplicity of a given configuration.
- Identify that all microstates are equally probable but the configurations with more microstates are more probable than the other configurations.
- Apply Boltzmann’s entropy equation to calculate the entropy associated with a multiplicity.

#### Key Ideas

- The entropy of a system can be defined in terms of the possible distributions of its molecules. For identical molecules, each possible distribution of molecules is called a microstate of the system. All equivalent microstates are grouped into a configuration of the system. The number of microstates in a configuration is the multiplicity $W$ of the configuration.
- For a system of $N$ molecules that may be distributed between the two halves of a box, the multiplicity is given by
  
  $$W = \frac{N!}{n_1! n_2!},$$

  in which $n_1$ is the number of molecules in one half of the box and $n_2$ is the number in the other half. A basic assumption of statistical mechanics is that all the microstates are equally probable.

Thus, configurations with a large multiplicity occur most often. When $N$ is very large (say, $N = 10^{22}$ molecules or more), the molecules are nearly always in the configuration in which $n_1 = n_2$.

- The multiplicity $W$ of a configuration of a system and the entropy $S$ of the system in that configuration are related by Boltzmann’s entropy equation:
  
  $$S = k \ln W,$$

  where $k = 1.38 \times 10^{-23} \text{J/K}$ is the Boltzmann constant.

- When $N$ is very large (the usual case), we can approximate $\ln N!$ with Stirling’s approximation:
  
  $$\ln N! \approx N(\ln N) - N.$$

#### A Statistical View of Entropy

In Chapter 19 we saw that the macroscopic properties of gases can be explained in terms of their microscopic, or molecular, behavior. Such explanations are part of a study called statistical mechanics. Here we shall focus our attention on a single problem, one involving the distribution of gas molecules between the two halves of an insulated box. This problem is reasonably simple to analyze, and it allows us to use statistical mechanics to calculate the entropy change for the free expansion of an ideal gas. You will see that statistical mechanics leads to the same entropy change as we would find using thermodynamics.
Figure 20-17 shows a box that contains six identical (and thus indistinguishable) molecules of a gas. At any instant, a given molecule will be in either the left or the right half of the box; because the two halves have equal volumes, the molecule has the same likelihood, or probability, of being in either half.

Table 20-1 shows the seven possible configurations of the six molecules, each configuration labeled with a Roman numeral. For example, in configuration I, all six molecules are in the left half of the box \( n_1 = 6 \) and none are in the right half \( n_2 = 0 \). We see that, in general, a given configuration can be achieved in a number of different ways. We call these different arrangements of the molecules microstates. Let us see how to calculate the number of microstates that correspond to a given configuration.

Suppose we have \( N \) molecules, distributed with \( n_1 \) molecules in one half of the box and \( n_2 \) in the other. (Thus \( n_1 + n_2 = N \).) Let us imagine that we distribute the molecules “by hand,” one at a time. If \( N = 6 \), we can select the first molecule in six independent ways; that is, we can pick any one of the six molecules. We can pick the second molecule in five ways, by picking any one of the remaining five molecules; and so on. The total number of ways in which we can select all six molecules is the product of these independent ways, or \( 6 \times 5 \times 4 \times 3 \times 2 \times 1 = 720 \).

In mathematical shorthand we write this product as \( 6! = 720 \), where \( 6! \) is pronounced “six factorial.” Your hand calculator can probably calculate factorials. For later use you will need to know that \( 0! = 1 \). (Check this on your calculator.)

However, because the molecules are indistinguishable, these 720 arrangements are not all different. In the case that \( n_1 = 4 \) and \( n_2 = 2 \) (which is configuration III in Table 20-1), for example, the order in which you put four molecules in one half of the box does not matter, because after you have put all four in, there is no way that you can tell the order in which you did so. The number of ways in which you can order the four molecules is \( 4! = 24 \). Similarly, the number of ways in which you can order two molecules for the other half of the box is simply \( 2! = 2 \). To get the number of different arrangements that lead to the \((4, 2)\) split of configuration III, we must divide 720 by 24 and also by 2. We call the resulting quantity, which is the number of microstates that correspond to a given configuration, the multiplicity \( W \) of that configuration. Thus, for configuration III,

\[
W_{III} = \frac{6!}{4! \times 2!} = \frac{720}{24 \times 2} = 15.
\]

Thus, Table 20-1 tells us there are 15 independent microstates that correspond to configuration III. Note that, as the table also tells us, the total number of microstates for six molecules distributed over the seven configurations is 64.

Extrapolating from six molecules to the general case of \( N \) molecules, we have

\[
W = \frac{N!}{n_1! \times n_2!} \quad \text{(multiplicity of configuration).}
\]
You should verify the multiplicities for all the configurations in Table 20-1.

The basic assumption of statistical mechanics is that

All microstates are equally probable.

In other words, if we were to take a great many snapshots of the six molecules as they jostle around in the box, we would find that all 64 microstates would occur equally often. Thus the system will spend, on average, the same amount of time in each of the 64 microstates.

Because all microstates are equally probable but different configurations have different numbers of microstates, the configurations are not all equally probable. In Table 20-1 configuration IV, with 20 microstates, is the most probable configuration, with a probability of $20/64 = 0.313$. This result means that the system is in configuration IV 31.3% of the time. Configurations I and VII, in which all the molecules are in one half of the box, are the least probable, each with a probability of $1/64 = 0.016$ or 1.6%. It is not surprising that the most probable configuration is the one in which the molecules are evenly divided between the two halves of the box, because that is what we expect at thermal equilibrium. However, it is surprising that there is any probability, however small, of finding all six molecules clustered in half of the box, with the other half empty.

For large values of $N$ there are extremely large numbers of microstates, but nearly all the microstates belong to the configuration in which the molecules are divided equally between the two halves of the box, as Fig. 20-18 indicates. Even though the measured temperature and pressure of the gas remain constant, the gas is churning away endlessly as its molecules “visit” all probable microstates with equal probability. However, because so few microstates lie outside the very narrow central configuration peak of Fig. 20-18, we might as well assume that the gas molecules are always divided equally between the two halves of the box. As we shall see, this is the configuration with the greatest entropy.

Sample Problem 20.05  Microstates and multiplicity

Suppose that there are 100 indistinguishable molecules in the box of Fig. 20-17. How many microstates are associated with the configuration $n_1 = 50$ and $n_2 = 50$, and with the configuration $n_1 = 100$ and $n_2 = 0$? Interpret the results in terms of the relative probabilities of the two configurations.

**KEY IDEA**

The multiplicity $W$ of a configuration of indistinguishable molecules in a closed box is the number of independent microstates with that configuration, as given by Eq. 20-20.

**Calculations:**

Thus, for the $(n_1, n_2)$ configuration $(50, 50)$,

$$W = \frac{N!}{n_1! n_2!} = \frac{100!}{50! 50!} = \frac{9.33 \times 10^{57}}{(3.04 \times 10^{64})(3.04 \times 10^{64})} = 1.01 \times 10^{29}. \quad \text{(Answer)}$$

Similarly, for the configuration $(100, 0)$, we have

$$W = \frac{N!}{n_1! n_2!} = \frac{100!}{100! 0!} = \frac{1}{1} = 1. \quad \text{(Answer)}$$

**The meaning:** Thus, a 50–50 distribution is more likely than a 100–0 distribution by the enormous factor of about $1 \times 10^{29}$. If you could count, at one per nanosecond, the number of microstates that correspond to the 50–50 distribution, it would take you about $3 \times 10^{12}$ years, which is about 200 times longer than the age of the universe. Keep in mind that the 100 molecules used in this sample problem is a very small number. Imagine what these calculated probabilities would be like for a mole of molecules, say about $N = 10^{24}$. Thus, you need never worry about suddenly finding all the air molecules clustering in one corner of your room, with you gasping for air in another corner. So, you can breathe easy because of the physics of entropy.
Probability and Entropy

In 1877, Austrian physicist Ludwig Boltzmann (the Boltzmann of Boltzmann’s constant $k$) derived a relationship between the entropy $S$ of a configuration of a gas and the multiplicity $W$ of that configuration. That relationship is

$$ S = k \ln W \quad \text{(Boltzmann's entropy equation).} \quad (20-21) $$

This famous formula is engraved on Boltzmann’s tombstone.

It is natural that $S$ and $W$ should be related by a logarithmic function. The total entropy of two systems is the sum of their separate entropies. The probability of occurrence of two independent systems is the product of their separate probabilities. Because $\ln ab = \ln a + \ln b$, the logarithm seems the logical way to connect these quantities.

Table 20-1 displays the entropies of the configurations of the six-molecule system of Fig. 20-17, computed using Eq. 20-21. Configuration IV, which has the greatest multiplicity, also has the greatest entropy.

When you use Eq. 20-20 to calculate $W$, your calculator may signal “OVERFLOW” if you try to find the factorial of a number greater than a few hundred. Instead, you can use Stirling’s approximation for $\ln N!$:

$$ \ln N! = N(\ln N) - N \quad \text{(Stirling’s approximation).} \quad (20-22) $$

The Stirling of this approximation was an English mathematician and not the Robert Stirling of engine fame.

Checkpoint 5

A box contains 1 mol of a gas. Consider two configurations: (a) each half of the box contains half the molecules and (b) each third of the box contains one-third of the molecules. Which configuration has more microstates?

Sample Problem 20.06  Entropy change of free expansion using microstates

In Sample Problem 20.01, we showed that when $n$ moles of an ideal gas doubles its volume in a free expansion, the entropy increase from the initial state $i$ to the final state $f$ is $S_f - S_i = nR \ln 2$. Derive this increase in entropy by using statistical mechanics.

**KEY IDEA**

We can relate the entropy $S$ of any given configuration of the molecules in the gas to the multiplicity $W$ of microstates for that configuration, using Eq. 20-21 ($S = k \ln W$).

**Calculations:** We are interested in two configurations: the final configuration $f$ (with the molecules occupying the full volume of their container in Fig. 20-1b) and the initial configuration $i$ (with the molecules occupying the left half of the container). Because the molecules are in a closed container, we can calculate the multiplicity $W$ of their microstates with Eq. 20-20. Here we have $N$ molecules in the $n$ moles of the gas. Initially, with the molecules all in the left half of the container, their $(n_1, n_2)$ configuration is $(N, 0)$. Then, Eq. 20-20 gives their multiplicity as

$$ W_i = \frac{N!}{N! 0!} = 1. $$

Finally, with the molecules spread through the full volume, their $(n_1, n_2)$ configuration is $(N/2, N/2)$. Then, Eq. 20-20 gives their multiplicity as

$$ W_f = \frac{N!}{(N/2)! (N/2)!}. $$

From Eq. 20-21, the initial and final entropies are

$$ S_i = k \ln W_i = k \ln 1 = 0 $$

and

$$ S_f = k \ln W_f = k \ln(N!) - 2k \ln[(N/2)!]. \quad (20-23) $$

In writing Eq. 20-23, we have used the relation

$$ \ln \frac{a}{b^2} = \ln a - 2 \ln b. $$
Now, applying Eq. 20-22 to evaluate Eq. 20-23, we find that
\[ S_f = k \ln(N!) - 2k \ln[(N/2)!] \]
\[ = k\{N(\ln N) - N \} - 2k\{(N/2) \ln(N/2) - (N/2)\} \]
\[ = k\{N(\ln N) - N - N \ln(N/2) + N\} \]
\[ = k\{N(\ln N) - N(\ln N - \ln 2)\} = Nk \ln 2 \]  \hspace{0.5cm} (20-24)

From Eq. 19-8 we can substitute \( nR \) for \( Nk \), where \( R \) is the universal gas constant. Equation 20-24 then becomes
\[ S_f = nR \ln 2. \]
The change in entropy from the initial state to the final is thus
\[ S_f - S_i = nR \ln 2 - 0 \]
\[ = nR \ln 2, \] \hspace{0.5cm} (Answer)

which is what we set out to show. In the first sample problem of this chapter we calculated this entropy increase for a free expansion with thermodynamics by finding an equivalent reversible process and calculating the entropy change for that process in terms of temperature and heat transfer. In this sample problem, we calculate the same increase in entropy with statistical mechanics using the fact that the system consists of molecules. In short, the two, very different approaches give the same answer.

### Review & Summary

#### One-Way Processes
An **irreversible process** is one that cannot be reversed by means of small changes in the environment. The direction in which an irreversible process proceeds is set by the change in **entropy** \( \Delta S \) of the system undergoing the process. Entropy \( S \) is a **state property** (or **state function**) of the system; that is, it depends only on the state of the system and not on the way in which the system reached that state. The entropy postulate states (in part): If an irreversible process occurs in a closed system, the entropy of the system always increases.

### Calculating Entropy Change
The **entropy change** \( \Delta S \) for an irreversible process that takes a system from an initial state \( i \) to a final state \( f \) is exactly equal to the entropy change \( \Delta S \) for any **reversible process** that takes the system between those same two states. We can compute the latter (but not the former) with

\[ \Delta S = S_f - S_i = \int_{i}^{f} \frac{dQ}{T} \]  \hspace{0.5cm} (20-1)

Here \( Q \) is the energy transferred as heat to or from the system during the process, and \( T \) is the temperature of the system in kelvins during the process.

For a reversible isothermal process, Eq. 20-1 reduces to

\[ \Delta S = S_f - S_i = \frac{Q}{T} \]  \hspace{0.5cm} (20-2)

When the temperature change \( \Delta T \) of a system is small relative to the temperature (in kelvins) before and after the process, the entropy change can be approximated as

\[ \Delta S = S_f - S_i \approx \frac{Q}{T_{\text{avg}}} \]  \hspace{0.5cm} (20-3)

where \( T_{\text{avg}} \) is the system’s average temperature during the process.

When an ideal gas changes reversibly from an initial state with temperature \( T_{i} \) and volume \( V_{i} \) to a final state with temperature \( T_{f} \) and volume \( V_{f} \), the change \( \Delta S \) in the entropy of the gas is

\[ \Delta S = S_f - S_i = nR \ln \frac{V_{f}}{V_{i}} + nC_{V} \ln \frac{T_{f}}{T_{i}} \]  \hspace{0.5cm} (20-4)

This law, which is an extension of the entropy postulate, states: *If a process occurs in a closed system, the entropy of the system increases for irreversible processes and remains constant for reversible processes. It never decreases.* In equation form,

\[ \Delta S \geq 0. \]  \hspace{0.5cm} (20-5)

#### Engines
An **engine** is a device that, operating in a cycle, extracts energy as heat \( |Q_{h}| \) from a high-temperature reservoir and does a certain amount of work \( |W| \). The **efficiency** \( \varepsilon \) of any engine is defined as

\[ \varepsilon = \frac{\text{energy we get}}{\text{energy we pay for}} = \frac{|W|}{|Q_{h}|}. \]  \hspace{0.5cm} (20-11)

In an **ideal engine**, all processes are reversible and no wasteful energy transfers occur due to, say, friction and turbulence. A **Carnot engine** is an ideal engine that follows the cycle of Fig. 20-9. Its efficiency is

\[ \varepsilon_{C} = 1 - \frac{|Q_{L}|}{|Q_{H}|} = 1 - \frac{T_{L}}{T_{H}}, \]  \hspace{0.5cm} (20-12, 20-13)

in which \( T_{H} \) and \( T_{L} \) are the temperatures of the high- and low-temperature reservoirs, respectively. Real engines always have an efficiency lower than that given by Eq. 20-13. Ideal engines that are not Carnot engines also have lower efficiencies.

A **perfect engine** is an imaginary engine in which energy extracted as heat from the high-temperature reservoir is converted completely to work. Such an engine would violate the second law of thermodynamics, which can be restated as follows: No series of processes is possible whose sole result is the absorption of energy as heat from a thermal reservoir and the complete conversion of this energy to work.

#### Refrigerators
A **refrigerator** is a device that, operating in a cycle, has work \( W \) done on it as it extracts energy \( |Q_{L}| \) as heat from a low-temperature reservoir. The coefficient of performance \( K \) of a refrigerator is defined as

\[ K = \frac{\text{what we want}}{\text{what we pay for}} = \frac{|Q_{L}|}{|W|}. \]  \hspace{0.5cm} (20-14)

A **Carnot refrigerator** is a Carnot engine operating in reverse.
For a Carnot refrigerator, Eq. 20-14 becomes

\[ K_c = \frac{|Q_H|}{Q_H - Q_L} = \frac{T_H}{T_H - T_L}. \] (20-15, 20-16)

A perfect refrigerator is an imaginary refrigerator in which energy extracted as heat from the low-temperature reservoir is converted completely to heat discharged to the high-temperature reservoir, without any need for work. Such a refrigerator would violate the second law of thermodynamics, which can be restated as follows: No series of processes is possible whose sole result is the transfer of energy as heat from a reservoir at a given temperature to a reservoir at a higher temperature.

Entropy from a Statistical View The entropy of a system can be defined in terms of the possible distributions of its molecules. For identical molecules, each possible distribution of molecules is called a microstate of the system. All equivalent microstates are grouped into a configuration of the system. The number of microstates in a configuration is the multiplicity \( W \) of the configuration.

For a system of \( N \) molecules that may be distributed between the two halves of a box, the multiplicity is given by

\[ W = \frac{N!}{n_1!n_2!}, \] (20-20)

in which \( n_1 \) is the number of molecules in one half of the box and \( n_2 \) is the number in the other half. A basic assumption of statistical mechanics is that all the microstates are equally probable. Thus, configurations with a large multiplicity occur most often.

The multiplicity \( W \) of a configuration of a system and the entropy \( S \) of the system in that configuration are related by Boltzmann’s entropy equation:

\[ S = k \ln W, \] (20-21)

where \( k = 1.38 \times 10^{-23} \text{ J/K} \) is the Boltzmann constant.

Questions

1. Point \( i \) in Fig. 20-19 represents the initial state of an ideal gas at temperature \( T \). Taking algebraic signs into account, rank the entropy changes that the gas undergoes as it moves, successively and reversibly, from point \( i \) to points \( a, b, c, \) and \( d \), greatest first.

2. In four experiments, blocks \( A \) and \( B \), starting at different initial temperatures, were brought together in an insulating box and allowed to reach a common final temperature. The entropy changes for the blocks in the four experiments had the following values (in joules per kelvin), but not necessarily in the order given. Determine which values for \( A \) go with which values for \( B \).

3. A gas, confined to an insulated cylinder, is compressed adiabatically to half its volume. Does the entropy of the gas increase, decrease, or remain unchanged during this process?

4. An ideal monatomic gas at initial temperature \( T_0 \) (in kelvins) expands from initial volume \( V_0 \) to volume \( 2V_0 \) by each of the five processes indicated in the \( T-V \) diagram of Fig. 20-20. In which process is the expansion (a) isothermal, (b) isobaric (constant pressure), and (c) adiabatic? Explain your answers. (d) In which processes does the entropy of the gas decrease?

5. In four experiments, 2.5 mol of hydrogen gas undergoes reversible isothermal expansions, starting from the same volume but at different temperatures. The corresponding \( p-V \) plots are shown in Fig. 20-21. Rank the situations according to the change in the entropy of the gas, greatest first.

6. A box contains 100 atoms in a configuration that has 50 atoms in each half of the box. Suppose that you could count the different microstates associated with this configuration at the rate of 100 billion states per second, using a supercomputer. Without written calculation, guess how much computing time you would need: a day, a year, or much more than a year.

7. Does the entropy per cycle increase, decrease, or remain the same for (a) a Carnot engine, (b) a real engine, and (c) a perfect engine (which is, of course, impossible to build)?

8. Three Carnot engines operate between temperature limits of (a) 400 and 500 K, (b) 500 and 600 K, and (c) 400 and 600 K. Each engine extracts the same amount of energy per cycle from the high-temperature reservoir. Rank the magnitudes of the work done by the engines per cycle, greatest first.

9. An inventor claims to have invented four engines, each of which operates between constant-temperature reservoirs at 400 and 300 K. Data on each engine, per cycle of operation, are: engine A, \( Q_H = 200 \text{ J}, Q_L = -175 \text{ J}, \) and \( W = 40 \text{ J}; \) engine B, \( Q_H = 500 \text{ J}, Q_L = -200 \text{ J}, \) and \( W = 400 \text{ J}; \) engine C, \( Q_H = 600 \text{ J}, Q_L = -200 \text{ J}, \) and \( W = 400 \text{ J}; \) engine D, \( Q_H = 100 \text{ J}, Q_L = -90 \text{ J}, \) and \( W = 10 \text{ J}. \) Of the first and second laws of thermodynamics, which (if either) does each engine violate?

10. Does the entropy per cycle increase, decrease, or remain the same for (a) a Carnot refrigerator, (b) a real refrigerator, and (c) a perfect refrigerator (which is, of course, impossible to build)?
Module 20-1  Entropy

1. SSM  Suppose 4.00 mol of an ideal gas undergoes a reversible isothermal expansion from volume $V_1$ to volume $V_2 = 2.00V_1$ at temperature $T = 400$ K. Find (a) the work done by the gas and (b) the entropy change of the gas. (c) If the expansion is reversible and adiabatic instead of isothermal, what is the entropy change of the gas?

2. An ideal gas undergoes a reversible isothermal expansion at 77.0°C, increasing its volume from 1.30 L to 3.40 L. The entropy change of the gas is 22.0 J/K. How many moles of gas are present?

3. ILW  A 2.50 mol sample of an ideal gas expands reversibly and isothermally at 360 K until its volume is doubled. What is the increase in entropy of the gas?

4. How much energy must be transferred as heat for a reversible isothermal expansion of an ideal gas at 132°C if the entropy of the gas increases by 46.0 J/K?

5. ILW  Find (a) the energy absorbed as heat and (b) the change in entropy of a 2.00 kg block of copper whose temperature is increased reversibly from 25.0°C to 100°C. The specific heat of copper is 386 J/kg⋅K.

6. (a) What is the entropy change of a 12.0 g ice cube that melts completely in a bucket of water whose temperature is just above the freezing point of water? (b) What is the entropy change of a 5.00 g spoonful of water that evaporates completely on a hot plate whose temperature is slightly above the boiling point of water?

7. ILW  A 50.0 g block of copper whose temperature is 400 K is placed in an insulating box with a 100 g block of lead whose temperature is 200 K. (a) What is the equilibrium temperature of the two-block system? (b) What is the change in the internal energy of the system between the initial state and the equilibrium state? (c) What is the change in the entropy of the system? (See Table 18-3.)

8. At very low temperatures, the molar specific heat $C_v$ of many solids is approximately $C_v = AT^3$, where $A$ depends on the particular substance. For aluminum, $A = 3.15 \times 10^{-5}$ J/mol⋅K$^3$. Find the entropy change for 4.00 mol of aluminum when its temperature is raised from 5.00 K to 10.0 K.

9. A 10 g ice cube at −10°C is placed in a lake whose temperature is 15°C. Calculate the change in entropy of the cube–lake system as the ice cube comes to thermal equilibrium with the lake. The specific heat of ice is 2220 J/kg⋅K. (Hint: Will the ice cube affect the lake temperature?)

10. A 364 g block is put in contact with a thermal reservoir. The block is initially at a lower temperature than the reservoir. Assume that the consequent transfer of energy as heat from the reservoir to the block is reversible. Figure 20-22 gives the change in entropy $\Delta S$ of the block until thermal equilibrium is reached. The scale of the horizontal axis is set by $T_a = 280$ K and $T_b = 380$ K. What is the specific heat of the block?

11. SSM  In an experiment, 200 g of aluminum (with a specific heat of 900 J/kg⋅K) at 100°C is mixed with 50.0 g of water at 20.0°C, with the mixture thermally isolated. (a) What is the equilibrium temperature? What are the entropy changes of (b) the aluminum, (c) the water, and (d) the aluminum–water system?

12. A gas sample undergoes a reversible isothermal expansion. Figure 20-23 gives the change $\Delta S$ in entropy of the gas versus the final volume $V_f$ of the gas. The scale of the vertical axis is set by $\Delta S_f = 64$ J/K. How many moles are in the sample?

13. In the irreversible process of Fig. 20-5, let the initial temperatures of the identical blocks $L$ and $R$ be 305.5 and 294.5 K, respectively, and let 215 J be the energy that must be transferred between the blocks in order to reach equilibrium. For the reversible processes of Fig. 20-6, what is $\Delta S$ for (a) block $L$, (b) its reservoir, (c) block $R$, (d) its reservoir, (e) the two-block system, and (f) the system of the two blocks and the two reservoirs?

14. (a) For 1.0 mol of a monatomic ideal gas taken through the cycle in Fig. 20-24, where $V_1 = 4.00V_0$, what is $W/pV_0$ as the gas goes from state $a$ to state $c$ along path $abc$? What is $\Delta E_{\text{int}}/pV_0$ in going (b) from $b$ to $c$ and (c) through one full cycle? What is $\Delta S$ in going (d) from $b$ to $c$ and (e) through one full cycle?

15. A mixture of 1773 g of water and 227 g of ice is in an initial equilibrium state at 0.00°C. The mixture is then, in a reversible process, brought to a second equilibrium state where the water–ice ratio, by mass, is 1.00:1.00 at 0.00°C. (a) Calculate the entropy change of the system during this process. (The heat of fusion for water is 333 kJ/kg.) (b) The system is then returned to the initial equilibrium state in an irreversible process (say, by using a Bunsen burner). Calculate the entropy change of the system during this process. (c) Are your answers consistent with the second law of thermodynamics?
**16** An 8.0 g ice cube at $-10^\circ$C is put into a Thermos flask containing 100 cm$^3$ of water at 20°C. By how much has the entropy of the cube–water system changed when equilibrium is reached? The specific heat of ice is 2220 J/kg·K.

**17** In Fig. 20-25, where $V_{23} = 3.00V_1$, $n$ moles of a diatomic ideal gas are taken through the cycle with the molecules rotating but not oscillating. What are (a) $p_2/p_1$, (b) $p_3/p_1$, and (c) $T_3/T_1$? For path 1 $\rightarrow$ 2, what are (d) $W/nRT_1$, (e) $Q/nRT_1$, (f) $\Delta E_{int}/nRT_1$, and (g) $\Delta S/nR$? For path 2 $\rightarrow$ 3, what are (h) $W/nRT_1$, (i) $Q/nRT_1$, (j) $\Delta E_{int}/nRT_1$, (k) $\Delta S/nR$? For path 3 $\rightarrow$ 1, what are (l) $W/nRT_1$, (m) $Q/nRT_1$, (n) $\Delta E_{int}/nRT_1$, and (o) $\Delta S/nR$?

**18** A 2.0 mol sample of an ideal monatomic gas undergoes the reversible process shown in Fig. 20-26. The scale of the vertical axis is set by $T_1 = 400.0$ K and the scale of the horizontal axis is set by $S_1 = 20.0$ J/K·K. (a) How much energy is absorbed as heat by the gas? (b) What is the change in the internal energy of the gas? (c) How much work is done by the gas?

**19** Suppose 1.00 mol of a monatomic ideal gas is taken from initial pressure $p_1$ and volume $V_1$ through two steps: (1) an isothermal expansion to volume $2.00V_1$ and (2) a pressure increase to $2.00p_1$ at constant volume. What is $Q/p_1V_1$ for (a) step 1 and (b) step 2? What is $W/p_1V_1$ for (c) step 1 and (d) step 2? For the full process, what are (e) $\Delta E_{int}/p_1V_1$ and (f) $\Delta S$? The gas is returned to its initial state and again taken to the same final state but now through these two steps: (1) an isothermal compression to pressure $2.00p_1$, and (2) a volume increase to $2.00V_1$ at constant pressure. What is $Q/p_1V_1$ for (g) step 1 and (h) step 2? What is $W/p_1V_1$ for (i) step 1 and (j) step 2? For the full process, what are (k) $\Delta E_{int}/p_1V_1$ and (l) $\Delta S$?

**20** Expand 1.00 mol of an monatomic gas initially at 5.00 kPa and 600 K from initial volume $V_i = 1.00$ m$^3$ to final volume $V_f = 2.00$ m$^3$. At any instant during the expansion, the pressure $p$ and volume $V$ of the gas are related by $p = 5.00 \exp[(V_i - V)/a]$, with $p$ in kilopascals, $V_i$ and $V$ in cubic meters, and $a = 1.00$ m$^3$. What are the final (a) pressure and (b) temperature of the gas? (c) How much work is done by the gas during the expansion? (d) What is $\Delta S$ for the expansion? (Hint: Use three simple reversible processes to find $\Delta S$.)

**21** Energy can be removed from water as heat at and even below the normal freezing point (0.0°C at atmospheric pressure) without causing the water to freeze; the water is then said to be supercooled. Suppose a 1.00 g water drop is supercooled until its temperature is that of the surrounding air, which is at $-5.00^\circ$C. The drop then suddenly and irreversibly freezes, transferring energy to the air as heat. What is the entropy change for the drop? (Hint: Use a three-step reversible process as if the water were taken through the normal freezing point.) The specific heat of ice is 2220 J/kg·K.

**22** An insulated Thermos contains 130 g of water at 80°C. You put in a 12.0 g ice cube at 0°C to form a system of ice + original water. (a) What is the equilibrium temperature of the system? What are the entropy changes of the water that was originally the ice cube (b) as it melts and (c) as it warms to the equilibrium temperature? (d) What is the entropy change of the original water as it cools to the equilibrium temperature? (e) What is the net entropy change of the ice + original water system as it reaches the equilibrium temperature?

**Module 20-2** Entropy in the Real World: Engines

**23** A Carnot engine whose low-temperature reservoir is at 17°C has an efficiency of 40%. By how much should the temperature of the high-temperature reservoir be increased to increase the efficiency to 50%?

**24** A Carnot engine absorbs 52 kJ as heat and exhausts 36 kJ as heat in each cycle. Calculate (a) the engine’s efficiency and (b) the work done per cycle in kilojoules.

**25** A Carnot engine has an efficiency of 22.0%. It operates between constant-temperature reservoirs differing in temperature by 75.0°C. What is the temperature of the (a) lower-temperature and (b) higher-temperature reservoir?

**26** In a hypothetical nuclear fusion reactor, the fuel is deuterium gas at a temperature of $7 \times 10^4$ K. If this gas could be used to operate a Carnot engine with $T_k = 100$°C, what would be the engine’s efficiency? Take both temperatures to be exact and report your answer to seven significant figures.

**27** A Carnot engine operates between 235°C and 115°C, absorbing $6.30 \times 10^4$ J per cycle at the higher temperature. (a) What is the efficiency of the engine? (b) How much work per cycle is this engine capable of performing?

**28** In the first stage of a two-stage Carnot engine, energy is absorbed as heat $Q_1$ at temperature $T_1$, work $W_1$ is done, and energy is expelled as heat $Q_2$ at a lower temperature $T_2$. The second stage absorbs energy as heat $Q_2$, does work $W_2$, and expels energy as heat $Q_3$ at a still lower temperature $T_3$. Prove that the efficiency of the engine is $(T_1 - T_3)/T_1$.

**29** Figure 20-27 shows a reversible cycle through which 1.00 mol of a monatomic ideal gas is taken. Assume that $p = 2p_0 \sqrt{V/V_0}$, $V = 2V_0$, $p_0 = 1.01 \times 10^5$ Pa, and $V_0 = 0.0225$ m$^3$. Calculate (a) the work done during the cycle, (b) the energy added as heat during stroke abc, and (c) the efficiency of the cycle. (d) What is the efficiency of a Carnot engine operating between the highest and lowest temperatures that occur in the cycle? (e) Is this greater than or less than the efficiency calculated in (c)?

**30** A 500 W Carnot engine operates between constant-temperature reservoirs at 100°C and 60.0°C. What is the rate at which energy is (a) taken in by the engine as heat and (b) exhausted by the engine as heat?

**31** The efficiency of a particular car engine is 25% when the engine does 8.2 kJ of work per cycle. Assume the process is reversible. What are (a) the energy the engine gains per cycle as heat $Q_{gain}$ from the fuel combustion and (b) the energy the engine loses per cycle as heat $Q_{lost}$? If a tune-up increases the efficiency to 31%, what are (c) $Q_{gain}$ and (d) $Q_{lost}$ at the same work value?
A Carnot engine is set up to produce a certain work $W$ per cycle. In each cycle, energy in the form of heat $Q_H$ is transferred to the working substance of the engine from the higher-temperature thermal reservoir, which is at an adjustable temperature $T_H$. The lower-temperature thermal reservoir is maintained at temperature $T_L = 250$ K. Figure 20-28 gives $Q_H$ for a range of $T_H$. The scale of the vertical axis is set by $Q_H = 6.0$ kJ. If $T_H$ is set at 550 K, what is $Q_H$?

**Problem 32**

A Carnot engine is set up to produce a certain work $W$ per cycle. In each cycle, energy in the form of heat $Q_H$ is transferred to the working substance of the engine from the higher-temperature thermal reservoir, which is at an adjustable temperature $T_H$. The lower-temperature thermal reservoir is maintained at temperature $T_L = 250$ K. Figure 20-28 gives $Q_H$ for a range of $T_H$. The scale of the vertical axis is set by $Q_H = 6.0$ kJ. If $T_H$ is set at 550 K, what is $Q_H$?

**Problem 33**

Figure 20-29 shows a reversible cycle through which 1.0 mol of a monatomic ideal gas is taken. Volume $V_c = 8.00V_b$. Process $bc$ is an adiabatic expansion, with $p_b = 10.0$ atm and $V_b = 1.00 \times 10^{-3}$ m$^3$. For the cycle, find (a) the energy added to the gas as heat, (b) the energy leaving the gas as heat, (c) the net work done by the gas, and (d) the efficiency of the cycle.

**Problem 34**

An ideal gas (1.0 mol) is the working substance in an engine that operates on the cycle shown in Fig. 20-30. Processes $BC$ and $DA$ are reversible and adiabatic. (a) Is the gas monatomic, diatomic, or polyatomic? (b) What is the engine efficiency?

**Problem 35**

The cycle in Fig. 20-31 represents the operation of a gasoline internal combustion engine. Volume $V_1 = 4.00V_b$. Assume the gasoline-air intake mixture is an ideal gas with $\gamma = 1.30$. What are the ratios (a) $T_2/T_1$, (b) $T_3/T_1$, (c) $T_4/T_1$, (d) $p_3/p_1$, and (e) $p_4/p_1$? (f) What is the engine efficiency?

**Module 20-3**

Refrigerators and Real Engines

How much work must be done by a Carnot refrigerator to transfer 1.0 J as heat (a) from a reservoir at 7.0°C to one at 27°C, (b) from a reservoir at −73°C to one at 27°C, (c) from a reservoir at −173°C to one at 27°C, and (d) from a reservoir at −223°C to one at 27°C?

**Problem 36**

How much work must be done by a Carnot refrigerator to transfer 1.0 J as heat (a) from a reservoir at 7.0°C to one at 27°C, (b) from a reservoir at −73°C to one at 27°C, (c) from a reservoir at −173°C to one at 27°C, and (d) from a reservoir at −223°C to one at 27°C?

**Problem 37**

A Carnot heat pump is used to heat a building. The external temperature is less than the internal temperature. The pump's coefficient of performance is 3.8, and the heat pump delivers 7.54 MJ as heat to the building each hour. If the heat pump is a Carnot engine working in reverse, at what rate must work be done to run it?

**Problem 38**

The electric motor of a heat pump transfers energy as heat from the outdoors, which is at −5.0°C, to a room that is at 17°C. If the heat pump were a Carnot heat pump (a Carnot engine working in reverse), how much energy would be transferred as heat to the room for each joule of electric energy consumed?

**Problem 39**

A Carnot air conditioner takes energy from the thermal energy of a room at 70°F and transfers it as heat to the outdoors, which is at 96°F. For each joule of electric energy required to operate the air conditioner, how many joules are removed from the room?

**Problem 40**

To make ice, a freezer that is a reverse Carnot engine extracts 42 kJ as heat at −15°C during each cycle, with coefficient of performance 5.7. The room temperature is 30.3°C. How much (a) energy per cycle is delivered as heat to the room and (b) work per cycle is required to run the freezer?

**Problem 41**

An air conditioner operating between 93°F and 70°F is rated at 4000 Btu/h cooling capacity. Its coefficient of performance is 27% of that of a Carnot refrigerator operating between the same two temperatures. What horsepower is required of the air conditioner motor?

**Problem 42**

The motor in a refrigerator has a power of 200 W. If the freezing compartment is at 270 K and the outside air is at 300 K, and assuming the efficiency of a Carnot refrigerator, what is the maximum amount of energy that can be extracted as heat from the freezing compartment in 10.0 min?

**Problem 43**

Figure 20-32 represents a Carnot engine that works between temperatures $T_1 = 400$ K and $T_2 = 150$ K and drives a Carnot refrigerator that works between temperatures $T_3 = 325$ K and $T_4 = 225$ K. What is the ratio $Q_3/Q_1$?

**Problem 44**

(a) During each cycle, a Carnot engine absorbs 750 J as heat from a high-temperature reservoir at 360 K, with the low-temperature reservoir at 280 K. How much work is done per cycle? (b) The engine is then made to work in reverse to function as a Carnot refrigerator between those same two reservoirs. During each cycle, how much work is required to remove 1200 J as heat from the low-temperature reservoir?

**Module 20-4**

A Statistical View of Entropy

Construct a table like Table 20-1 for eight molecules.

**Problem 45**

A box contains $N$ identical gas molecules equally divided between its two halves. For $N = 50$, what are (a) the multiplicity $W$ of the central configuration, (b) the total number of microstates, and (c) the percentage of the time the system spends in the central configuration? For $N = 100$, what are (d) $W$ of the central configura-
tion, (e) the total number of microstates, and (f) the percentage of the time the system spends in the central configuration? For \( N = 200 \), what are (g) \( W \) of the central configuration, (h) the total number of microstates, and (i) the percentage of the time the system spends in the central configuration? (j) Does the time spent in the central configuration increase or decrease with an increase in \( N \)?

**Additional Problems**

47 **SSM** A box contains \( N \) gas molecules. Consider the box to be divided into three equal parts. (a) By extension of Eq. 20-20, write a formula for the multiplicity of any given configuration. (b) Consider two configurations: configuration \( A \) with equal numbers of molecules in all three of the box, and configuration \( B \) with equal numbers of molecules in each half of the box divided into two equal parts rather than three. What is the ratio \( W_A/W_B \) of the multiplicity of configuration \( A \) to that of configuration \( B \)? (c) Evaluate \( W_A/W_B \) for \( N = 100 \). (Because 100 is not evenly divisible by 3, put 34 molecules into one of the three box parts of configuration \( A \) and 33 in each of the other two parts.)

48 Four particles are in the insulated box of Fig. 20-17. What are (a) the least multiplicity, (b) the greatest multiplicity, (c) the least entropy, and (d) the greatest entropy of the four-particle system?

49 A cylindrical copper rod of length 1.50 m and radius 2.00 cm is insulated to prevent heat loss through its curved surface. One end is attached to a thermal reservoir fixed at 300°C; the other is attached to a thermal reservoir fixed at 30.0°C. What is the rate at which entropy increases for the rod–reservoir system?

50 Suppose 0.550 mol of an ideal gas is isothermally and reversibly expanded in the four situations given below. What is the change in the entropy of the gas for each situation?

<table>

51 **SSM** As a sample of nitrogen gas \( (N_2) \) undergoes a temperature increase at constant volume, the distribution of molecular speeds increases. That is, the probability distribution function \( P(v) \) for the molecules spreads to higher speed values, as suggested in Fig. 19-8b. One way to report the spread in \( P(v) \) is to measure the difference \( \Delta v \) between the most probable speed \( v_m \) and the rms speed \( v_{\text{rms}} \). When \( P(v) \) spreads to higher speeds, \( \Delta v \) increases. Assume that the gas is ideal and the \( N_2 \) molecules rotate but do not oscillate. For 1.5 mol, an initial temperature of 250 K, and a final temperature of 500 K, what are (a) the initial difference \( \Delta v_m \), (b) the final difference \( \Delta v_f \), and (c) the entropy change \( \Delta S \) for the gas?

52 Suppose 1.0 mol of a monatomic ideal gas initially at 10 L and 300 K is heated at constant volume to 600 K, allowed to expand isothermally to its initial pressure, and finally compressed at constant volume to its original volume, pressure, and temperature. During the cycle, what are (a) the net energy entering the system (the gas) as heat and (b) the net work done by the gas? (c) What is the efficiency of the cycle?

53 Suppose that a deep shaft were drilled in Earth’s crust near one of the poles, where the surface temperature is \( -40°C \), to a depth where the temperature is 800°C. (a) What is the theoretical limit to the efficiency of an engine operating between these temperatures? (b) If all the energy released as heat into the low-temperature reservoir were used to melt ice that was initially at \(-40°C\), at what rate could liquid water at 0°C be produced by a 100 MW power plant (treat it as an engine)? The specific heat of ice is 2220 J/kg⋅K; water’s heat of fusion is 333 kJ/kg. (Note that the engine can operate only between 0°C and 800°C in this case. Energy exhausted at \(-40°C\) cannot warm anything above \(-40°C\).)

54 What is the entropy change for 3.20 mol of an ideal monatomic gas undergoing a reversible increase in temperature from 380 K to 425 K at constant volume?

55 A 600 g lump of copper at 80.0°C is placed in 70.0 g of water at 10.0°C in an insulated container. (See Table 18-3 for specific heats.) (a) What is the equilibrium temperature of the copper–water system? What entropy changes do (b) the copper, (c) the water, and (d) the copper–water system undergo in reaching the equilibrium temperature?

56 Figure 20-33 gives the force magnitude \( F \) versus stretch distance \( x \) for a rubber band, with the scale of the \( F \) axis set by \( F_1 = 1.50 \) N and the scale of the \( x \) axis set by \( x_1 = 3.50 \) cm. The temperature is 2.00°C. When the rubber band is stretched by \( x = 1.70 \) cm, at what rate does the entropy of the rubber band change during a small additional stretch?

57 The temperature of 1.00 mol of a monatomic ideal gas is raised reversibly from 300 K to 400 K, with its volume kept constant. What is the entropy change of the gas?

58 Repeat Problem 57, with the pressure now kept constant.

59 **SSM** A 0.600 kg sample of water is initially ice at temperature \(-20°C\). What is the sample’s entropy change if its temperature is increased to 40°C?

60 A three-step cycle is undergone by 3.4 mol of an ideal diatomic gas: (1) the temperature of the gas is increased from 200 K to 500 K at constant volume; (2) the gas is then isothermally expanded to its original pressure; (3) the gas is then contracted at constant pressure back to its original volume. Throughout the cycle, the molecules rotate but do not oscillate. What is the efficiency of the cycle?

61 An inventor has built an engine \( X \) and claims that its efficiency \( \varepsilon_X \) is greater than the efficiency \( \varepsilon \) of an ideal engine operating between the same two temperatures. Suppose you couple engine \( X \) to an ideal refrigerator (Fig. 20-34a) and adjust the cycle...
of engine X so that the work per cycle it provides equals the work per cycle required by the ideal refrigerator. Treat this combination as a single unit and show that if the inventor’s claim were true (if $e_X > e$), the combined unit would act as a perfect refrigerator (Fig. 20-34b), transferring energy as heat from the low-temperature reservoir to the high-temperature reservoir without the need for work.

62 Suppose 2.00 mol of a diatomic gas is taken reversibly around the cycle shown in the $T$-$S$ diagram of Fig. 20-35, where $S_1 = 6.00$ J/K and $S_2 = 8.00$ J/K. The molecules do not rotate or oscillate. What is the energy transferred as heat for (a) path $1 \rightarrow 2$, (b) path $2 \rightarrow 3$, and (c) the full cycle? (d) What is the work $W$ for the isothermal process? The volume $V_1$ in state 1 is 0.200 m$^3$. What is the volume in (e) state 2 and (f) state 3?

What is the change $\Delta E_{\text{int}}$ for (g) path $1 \rightarrow 2$, (h) path $2 \rightarrow 3$, and (i) the full cycle? (Hint: (h) can be done with one or two lines of calculation using Module 19-7 or with a page of calculation using Module 19-9.) (j) What is the work $W$ for the adiabatic process?

63 A three-step cycle is undergone reversibly by 4.00 mol of an ideal gas: (1) an adiabatic expansion that gives the gas 2.00 times its initial volume, (2) a constant-volume process, (3) an isothermal compression back to the initial state of the gas. We do not know whether the gas is monatomic or diatomic; if it is diatomic, we do not know whether the molecules are rotating or oscillating. What are the entropy changes for (a) the cycle, (b) process 1, (c) process 3, and (d) process 2?

64 (a) A Carnot engine operates between a hot reservoir at 320 K and a cold one at 260 K. If the engine absorbs 500 J as heat per cycle at the hot reservoir, how much work per cycle does it deliver? (b) If the engine working in reverse functions as a refrigerator between the same two reservoirs, how much work per cycle must be supplied to remove 1000 J as heat from the cold reservoir?

65 A 2.00 mol diatomic gas initially at 300 K undergoes this cycle: It is (1) heated at constant volume to 800 K, (2) then allowed to expand isothermally to its initial pressure, (3) then compressed at constant pressure to its initial state. Assuming the gas molecules neither rotate nor oscillate, find (a) the net energy transferred as heat to the gas, (b) the net work done by the gas, and (c) the efficiency of the cycle.

66 An ideal refrigerator does 150 J of work to remove 560 J as heat from its cold compartment. (a) What is the refrigerator’s coefficient of performance? (b) How much heat per cycle is exhausted to the kitchen?

67 Suppose that 260 J is conducted from a constant-temperature reservoir at 400 K to one at (a) 100 K, (b) 200 K, (c) 300 K, and (d) 360 K. What is the net change in entropy $\Delta S_{\text{net}}$ of the reservoirs in each case? (e) As the temperature difference of the two reservoirs decreases, does $\Delta S_{\text{net}}$ increase, decrease, or remain the same?

68 An apparatus that liquefies helium is in a room maintained at 300 K. If the helium in the apparatus is at 4.0 K, what is the minimum ratio $Q_{\text{in}}/Q_{\text{room}}$ where $Q_{\text{in}}$ is the energy delivered as heat to the room and $Q_{\text{room}}$ is the energy removed as heat from the helium?

69 A brass rod is in thermal contact with a constant-temperature reservoir at 130°C at one end and a constant-temperature reservoir at 24.0°C at the other end. (a) Compute the total change in entropy of the rod–reservoirs system when 5030 J of energy is conducted through the rod, from one reservoir to the other. (b) Does the entropy of the rod change?

70 A 45.0 g block of tungsten at 30.0°C and a 25.0 g block of silver at −120°C are placed together in an insulated container. What are (a) the temperature after equilibration, (b) the entropy change of tungsten, (c) the entropy change of silver, and (d) the total entropy change of the system?

71 A box contains $N$ molecules. Consider two configurations: configuration A with an equal division of the molecules between the two halves of the box, and configuration B with 60.0% of the molecules in the left half of the box and 40.0% in the right half. For $N = 50$, what are (a) the multiplicity $W_A$ of configuration A, (b) the multiplicity $W_B$ of configuration B, and (c) the ratio $f_{BA}$ of the time the system spends in configuration B to the time it spends in configuration A? For $N = 100$, what are (d) $W_A$, (e) $W_B$, and (f) $f_{BA}$? For $N = 200$, what are (g) $W_A$, (h) $W_B$, and (i) $f_{BA}$? (j) With increasing $N$, does $f_{BA}$ increase, decrease, or remain the same?

72 Calculate the efficiency of a fossil-fuel power plant that consumes 380 metric tons of coal each hour to produce useful work at the rate of 750 MW. The heat of combustion of coal (the heat due to burning it) is 28 MJ/kg.

73 A Carnot refrigerator extracts 35.0 kJ as heat during each cycle, operating with a coefficient of performance of 4.60. What are (a) the energy per cycle transferred as heat to the room and (b) the work done per cycle?

74 A Carnot engine whose high-temperature reservoir is at 400 K has an efficiency of 30.0%. By how much should the temperature of the low-temperature reservoir be changed to increase the efficiency to 40.0%?

75 System A of three particles and system B of five particles are in insulated boxes like that in Fig. 20-17. What is the least multiplicity $W$ of (a) system A and (b) system B? What is the greatest multiplicity $W$ of (c) A and (d) B? What is the greatest entropy of (e) A and (f) B?

76 Figure 20-36 shows a Carnot cycle on a $T$-$S$ diagram, with a scale set by $S_y = 0.60$ J/K. For a full cycle, find (a) the net heat transfer and (b) the net work done by the system.

77 Find the relation between the efficiency of a reversible ideal heat engine and the coefficient of performance of the reversible refrigerator obtained by running the engine backwards.

78 A Carnot engine has a power of 500 W. It operates between heat reservoirs at 100°C and 60.0°C. Calculate (a) the rate of heat input and (b) the rate of exhaust heat output.

79 In a real refrigerator, the low-temperature coils are at −13°C, and the compressed gas in the condenser is at 26°C. What is the theoretical coefficient of performance?
After reading this module, you should be able to . . .

21.01 Distinguish between being electrically neutral, negatively charged, and positively charged and identify excess charge.
21.02 Distinguish between conductors, nonconductors (insulators), semiconductors, and superconductors.
21.03 Describe the electrical properties of the particles inside an atom.
21.04 Identify conduction electrons and explain their role in making a conducting object negatively or positively charged.
21.05 Identify what is meant by “electrically isolated” and by “grounding.”
21.06 Explain how a charged object can set up induced charge in a second object.
21.07 Identify that charges with the same electrical sign repel each other and those with opposite electrical signs attract each other.
21.08 For either of the particles in a pair of charged particles, draw a free-body diagram, showing the electrostatic force (Coulomb force) on it and anchoring the tail of the force vector on that particle.
21.09 For either of the particles in a pair of charged particles, apply Coulomb’s law to relate the magnitude of the electrostatic force, the charge magnitudes of the particles, and the separation between the particles.

Key Ideas

- The strength of a particle’s electrical interaction with objects around it depends on its electric charge (usually represented as $q$), which can be either positive or negative. Particles with the same sign of charge repel each other, and particles with opposite signs of charge attract each other.
- An object with equal amounts of the two kinds of charge is electrically neutral, whereas one with an imbalance is electrically charged and has an excess charge.
- Conductors are materials in which a significant number of electrons are free to move. The charged particles in nonconductors (insulators) are not free to move.
- Electric current $i$ is the rate $dq/dt$ at which charge passes a point:
  $$ i = \frac{dq}{dt} $$
- Coulomb’s law describes the electrostatic force (or electric force) between two charged particles. If the particles have charges $q_1$ and $q_2$, are separated by distance $r$, and are at rest (or moving only slowly) relative to each other, then the magnitude of the force acting on each due to the other is given by
  $$ F = \frac{1}{4\pi\varepsilon_0} \frac{|q_1||q_2|}{r^2} $$
  (Coulomb’s law),

where $\varepsilon_0 = 8.85 \times 10^{-12}$ C$^2$/N·m$^2$ is the permittivity constant. The ratio $1/4\pi\varepsilon_0$ is often replaced with the electrostatic constant (or Coulomb constant) $k = 8.99 \times 10^9$ N·m$^2$/C$^2$.
- The electrostatic force vector acting on a charged particle due to a second charged particle is either directly toward the second particle (opposite signs of charge) or directly away from it (same sign of charge).
- If multiple electrostatic forces act on a particle, the net force is the vector sum (not scalar sum) of the individual forces.
What Is Physics?

You are surrounded by devices that depend on the physics of electromagnetism, which is the combination of electric and magnetic phenomena. This physics is at the root of computers, television, radio, telecommunications, household lighting, and even the ability of food wrap to cling to a container. This physics is also the basis of the natural world. Not only does it hold together all the atoms and molecules in the world, it also produces lightning, auroras, and rainbows.

The physics of electromagnetism was first studied by the early Greek philosophers, who discovered that if a piece of amber is rubbed and then brought near bits of straw, the straw will jump to the amber. We now know that the attraction between amber and straw is due to an electric force. The Greek philosophers also discovered that if a certain type of stone (a naturally occurring magnet) is brought near bits of iron, the iron will jump to the stone. We now know that the attraction between magnet and iron is due to a magnetic force.

From these modest origins with the Greek philosophers, the sciences of electricity and magnetism developed separately for centuries—until 1820, in fact, when Hans Christian Oersted found a connection between them: an electric current in a wire can deflect a magnetic compass needle. Interestingly enough, Oersted made this discovery, a big surprise, while preparing a lecture demonstration for his physics students.

The new science of electromagnetism was developed further by workers in many countries. One of the best was Michael Faraday, a truly gifted experimenter with a talent for physical intuition and visualization. That talent is attested to by the fact that his collected laboratory notebooks do not contain a single equation. In the mid-nineteenth century, James Clerk Maxwell put Faraday’s ideas into mathematical form, introduced many new ideas of his own, and put electromagnetism on a sound theoretical basis.

Our discussion of electromagnetism is spread through the next 16 chapters. We begin with electrical phenomena, and our first step is to discuss the nature of electric charge and electric force.

Electric Charge

Here are two demonstrations that seem to be magic, but our job here is to make sense of them. After rubbing a glass rod with a silk cloth (on a day when the humidity is low), we hang the rod by means of a thread tied around its center (Fig. 21-1a). Then we rub a second glass rod with the silk cloth and bring it near the hanging rod. The hanging rod magically moves away. We can see that a force repels it from the second rod, but how? There is no contact with that rod, no breeze to push on it, and no sound wave to disturb it.

In the second demonstration we replace the second rod with a plastic rod that has been rubbed with fur. This time, the hanging rod moves toward the nearby rod (Fig. 21-1b). Like the repulsion, this attraction occurs without any contact or obvious communication between the rods.

In the next chapter we shall discuss how the hanging rod knows of the presence of the other rods, but in this chapter let’s focus on just the forces that are involved. In the first demonstration, the force on the hanging rod was **repulsive**, and
in the second, *attractive.* After a great many investigations, scientists figured out that the forces in these types of demonstrations are due to the *electric charge* that we set up on the rods when they are in contact with silk or fur. Electric charge is an intrinsic property of the fundamental particles that make up objects such as the rods, silk, and fur. That is, charge is a property that comes automatically with those particles wherever they exist.

**Two Types.** There are two types of electric charge, named by the American scientist and statesman Benjamin Franklin as positive charge and negative charge. He could have called them anything (such as cherry and walnut), but using algebraic signs as names comes in handy when we add up charges to find the net charge. In most everyday objects, such as a mug, there are about equal numbers of negatively charged particles and positively charged particles, and so the net charge is zero, the charge is said to be *balanced*, and the object is said to be *electrically neutral* (or just *neutral* for short).

**Excess Charge.** Normally you are approximately neutral. However, if you live in regions where the humidity is low, you know that the charge on your body can become slightly unbalanced when you walk across certain carpets. Either you gain negative charge from the carpet (at the points of contact between your shoes with the carpet) and become negatively charged, or you lose negative charge and become positively charged. Either way, the extra charge is said to be an excess charge. You probably don't notice it until you reach for a door handle or another person. Then, if your excess charge is enough, a spark leaps between you and the other object, eliminating your excess charge. Such sparking can be annoying and even somewhat painful. Such *charging* and *discharging* does not happen in humid conditions because the water in the air neutralizes your excess charge about as fast as you acquire it.

Two of the grand mysteries in physics are (1) *why* does the universe have particles with electric charge (what is it, really?) and (2) *why* does electric charge come in two types (and not, say, one type or three types). We just do not know. Nevertheless, with lots of experiments similar to our two demonstrations scientists discovered that

\[ \text{Particles with the same sign of electrical charge repel each other, and particles with opposite signs attract each other.} \]

In a moment we shall put this rule into quantitative form as Coulomb’s law of *electrostatic force* (or *electric force*) between charged particles. The term *electrostatic* is used to emphasize that, relative to each other, the charges are either stationary or moving only very slowly.

**Demos.** Now let’s get back to the demonstrations to understand the motions of the rod as being something other than just magic. When we rub the glass rod with a silk cloth, a small amount of negative charge moves from the rod to the silk (a transfer like that between you and a carpet), leaving the rod with a small amount of excess positive charge. (Which way the negative charge moves is not obvious and requires a lot of experimentation.) We *rub* the silk over the rod to increase the number of contact points and thus the amount, still tiny, of transferred charge. We hang the rod from the thread so as to *electrically isolate* it from its surroundings (so that the surroundings cannot neutralize the rod by giving it enough negative charge to rebalance its charge). When we rub the second rod with the silk cloth, it too becomes positively charged. So when we bring it near the first rod, the two rods repel each other (Fig. 21-2a).

Next, when we rub the plastic rod with fur, it gains excess negative charge from the fur. (Again, the transfer direction is learned through many experiments.) When we bring the plastic rod (with negative charge) near the hanging glass rod (with positive charge), the rods are attracted to each other (Fig. 21-2b). All this is subtle. You cannot see the charge or its transfer, only the results.

![Figure 21-2](image-url) *(a) Two charged rods of the same sign repel each other. (b) Two charged rods of opposite signs attract each other. Plus signs indicate a positive net charge, and minus signs indicate a negative net charge.*
Conductors and Insulators

We can classify materials generally according to the ability of charge to move through them. **Conductors** are materials through which charge can move rather freely; examples include metals (such as copper in common lamp wire), the human body, and tap water. **Nonconductors**—also called **insulators**—are materials through which charge cannot move freely; examples include rubber (such as the insulation on common lamp wire), plastic, glass, and chemically pure water. **Semiconductors** are materials that are intermediate between conductors and insulators; examples include silicon and germanium in computer chips. **Superconductors** are materials that are perfect conductors, allowing charge to move without any hindrance. In these chapters we discuss only conductors and insulators.

**Conducting Path.** Here is an example of how conduction can eliminate excess charge on an object. If you rub a copper rod with wool, charge is transferred from the wool to the rod. However, if you are holding the rod while also touching a faucet, you cannot charge the rod in spite of the transfer. The reason is that you, the rod, and the faucet are all conductors connected, via the plumbing, to Earth’s surface, which is a huge conductor. Because the excess charges put on the rod by the wool repel one another, they move away from one another by moving first through the rod, then through you, and then through the faucet and plumbing to reach Earth’s surface, where they can spread out. The process leaves the rod electrically neutral.

In thus setting up a pathway of conductors between an object and Earth’s surface, we are said to **ground** the object, and in neutralizing the object (by eliminating an unbalanced positive or negative charge), we are said to **discharge** the object. If instead of holding the copper rod in your hand, you hold it by an insulating handle, you eliminate the conducting path to Earth, and the rod can then be charged by rubbing (the charge remains on the rod), as long as you do not touch it directly with your hand.

**Charged Particles.** The properties of conductors and insulators are due to the structure and electrical nature of atoms. Atoms consist of positively charged **protons**, negatively charged **electrons**, and electrically neutral **neutrons**. The protons and neutrons are packed tightly together in a central **nucleus**.

The charge of a single electron and that of a single proton have the same magnitude but are opposite in sign. Hence, an electrically neutral atom contains equal numbers of electrons and protons. Electrons are held near the nucleus because they have the electrical sign opposite that of the protons in the nucleus and thus are attracted to the nucleus. Were this not true, there would be no atoms and thus no you.

When atoms of a conductor like copper come together to form the solid, some of their outermost (and so most loosely held) electrons become free to wander about within the solid, leaving behind positively charged atoms (**positive ions**). We call the mobile electrons **conduction electrons**. There are few (if any) free electrons in a nonconductor.

**Induced Charge.** The experiment of Fig. 21-3 demonstrates the mobility of charge in a conductor. A negatively charged plastic rod will attract either end of an isolated neutral copper rod. What happens is that many of the conduction electrons in the closer end of the copper rod are repelled by the negative charge on the plastic rod. Some of the conduction electrons move to the far end of the copper rod, leaving the near end depleted in electrons and thus with an unbalanced positive charge. This positive charge is attracted to the negative charge in the plastic rod. Although the copper rod is still neutral, it is said to have an **induced charge**, which means that some of its positive and negative charges have been separated due to the presence of a nearby charge.

Similarly, if a positively charged glass rod is brought near one end of a neutral copper rod, induced charge is again set up in the neutral copper rod but now the near end gains conduction electrons, becomes negatively charged, and is attracted to the glass rod, while the far end is positively charged.
Note that only conduction electrons, with their negative charges, can move; positive ions are fixed in place. Thus, an object becomes positively charged only through the removal of negative charges.

**Blue Flashes from a Wintergreen LifeSaver**

Indirect evidence for the attraction of charges with opposite signs can be seen with a wintergreen LifeSaver (the candy shaped in the form of a marine lifesaver). If you adapt your eyes to darkness for about 15 minutes and then have a friend chomp on a piece of the candy in the darkness, you will see a faint blue flash from your friend’s mouth with each chomp. Whenever a chomp breaks a sugar crystal into pieces, each piece will probably end up with a different number of electrons. Suppose a crystal breaks into pieces $A$ and $B$, with $A$ ending up with more electrons on its surface than $B$ (Fig. 21-4). This means that $B$ has positive ions (atoms that lost electrons to $A$) on its surface. Because the electrons on $A$ are strongly attracted to the positive ions on $B$, some of those electrons jump across the gap between the pieces.

As $A$ and $B$ move away from each other, air (primarily nitrogen, $N_2$) flows into the gap, and many of the jumping electrons collide with nitrogen molecules in the air, causing the molecules to emit ultraviolet light. You cannot see this type of light. However, the wintergreen molecules on the surfaces of the candy pieces absorb the ultraviolet light and then emit blue light, which you can see — it is the blue light coming from your friend’s mouth.

**Checkpoint 1**

The figure shows five pairs of plates: $A$, $B$, and $D$ are charged plastic plates and $C$ is an electrically neutral copper plate. The electrostatic forces between the pairs of plates are shown for three of the pairs. For the remaining two pairs, do the plates repel or attract each other?

**Coulomb’s Law**

Now we come to the equation for Coulomb’s law, but first a caution. This equation works for only charged particles (and a few other things that can be treated as particles). For extended objects, with charge located in many different places, we need more powerful techniques. So, here we consider just charged particles and not, say, two charged cats.

If two charged particles are brought near each other, they each exert an *electrostatic force* on the other. The direction of the force vectors depends on the signs of the charges. If the particles have the same sign of charge, they repel each other. That means that the force vector on each is directly away from the other particle (Figs. 21-5 $a$ and $b$). If we release the particles, they accelerate away from each other. If, instead, the particles have opposite signs of charge, they attract each other. That means that the force vector on each is directly toward the other particle (Fig. 21-5 $c$). If we release the particles, they accelerate toward each other.

The equation for the electrostatic forces acting on the particles is called **Coulomb’s law** after Charles-Augustin de Coulomb, whose experiments in 1785 led him to it. Let’s write the equation in vector form and in terms of the particles shown in Fig. 21-6, where particle 1 has charge $q_1$ and particle 2 has charge $q_2$. (These symbols can represent either positive or negative charge.) Let’s also focus on particle 1 and write the force acting on it in terms of a unit vector \( \hat{r} \) that points along a radial
axis extending through the two particles, radially away from particle 2. (As with other unit vectors, \( \hat{r} \) has a magnitude of exactly 1 and no unit; its purpose is to point, like a direction arrow on a street sign.) With these decisions, we write the electrostatic force as

\[
\vec{F} = k \frac{q_1 q_2}{r^2} \hat{r} \quad \text{(Coulomb's law)},
\]

where \( r \) is the separation between the particles and \( k \) is a positive constant called the electrostatic constant or the Coulomb constant. (We'll discuss \( k \) below.)

Let's first check the direction of the force on particle 1 as given by Eq. 21-1. If \( q_1 \) and \( q_2 \) have the same sign, then the product \( q_1 q_2 \) gives us a positive result. So, Eq. 21-1 tells us that the force on particle 1 is in the direction of \( \hat{r} \). That checks, because particle 1 is being repelled from particle 2. Next, if \( q_1 \) and \( q_2 \) have opposite signs, the product \( q_1 q_2 \) gives us a negative result. So, now Eq. 21-1 tells us that the force on particle 1 is in the direction opposite \( \hat{r} \). That checks because particle 1 is being attracted toward particle 2.

An Aside. Here is something that is very curious. The form of Eq. 21-1 is the same as that of Newton’s equation (Eq. 13-3) for the gravitational force between two particles with masses \( m_1 \) and \( m_2 \) and separation \( r \):

\[
\vec{F} = G \frac{m_1 m_2}{r^2} \hat{r} \quad \text{(Newton's law)},
\]

where \( G \) is the gravitational constant. Although the two types of forces are wildly different, both equations describe inverse square laws (the \( 1/r^2 \) dependences) that involve a product of a property of the interacting particles—the charge in one case and the mass in the other. However, the laws differ in that gravitational forces are always attractive but electrostatic forces may be either attractive or repulsive, depending on the signs of the charges. This difference arises from the fact that there is only one type of mass but two types of charge.

Unit. The SI unit of charge is the coulomb. For practical reasons having to do with the accuracy of measurements, the coulomb unit is derived from the SI unit ampere for electric current \( i \). We shall discuss current in detail in Chapter 26, but here let’s just note that current \( i \) is the rate \( dq/dt \) at which charge moves past a point or through a region:

\[
i = \frac{dq}{dt} \quad \text{(electric current)}.
\]

Rearranging Eq. 21-3 and replacing the symbols with their units (coulombs \( C \), amperes \( A \), and seconds \( s \)) we see that

\[
1 \text{ C} = (1 \text{ A})(1 \text{ s}).
\]

Force Magnitude. For historical reasons (and because doing so simplifies many other formulas), the electrostatic constant \( k \) in Eq. 21-1 is often written as \( \frac{1}{4\pi\varepsilon_0} \). Then the magnitude of the electrostatic force in Coulomb’s law becomes

\[
F = \frac{1}{4\pi\varepsilon_0} \frac{|q_1||q_2|}{r^2} \quad \text{(Coulomb's law)}, \quad \text{(21-4)}
\]

The constants in Eqs. 21-1 and 21-4 have the value

\[
k = \frac{1}{4\pi\varepsilon_0} = 8.99 \times 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2.
\]

The quantity \( \varepsilon_0 \), called the permittivity constant, sometimes appears separately in equations and is

\[
\varepsilon_0 = 8.85 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2.
\]

Working a Problem. Note that the charge magnitudes appear in Eq. 21-4, which gives us the force magnitude. So, in working problems in this chapter, we use Eq. 21-4 to find the magnitude of a force on a chosen particle due to a second
particle and we separately determine the direction of the force by considering the charge signs of the two particles.

**Multiple Forces.** As with all forces in this book, the electrostatic force obeys the principle of superposition. Suppose we have \( n \) charged particles near a chosen particle called particle 1; then the net force on particle 1 is given by the vector sum

\[
\vec{F}_{1,\text{net}} = \vec{F}_{12} + \vec{F}_{13} + \vec{F}_{14} + \vec{F}_{15} + \cdots + \vec{F}_{1n},
\]

(21-7)
in which, for example, \( \vec{F}_{14} \) is the force on particle 1 due to the presence of particle 4.

This equation is the key to many of the homework problems, so let’s state it in words. If you want to know the net force acting on a chosen charged particle that is surrounded by other charged particles, first clearly identify that chosen particle and then find the force on it due to each of the other particles. Draw those force vectors in a free-body diagram of the chosen particle, with the tails anchored on the particle. (That may sound trivial, but failing to do so easily leads to errors.) Then add all those forces as vectors according to the rules of Chapter 3, not as scalars. (You cannot just willy-nilly add up their magnitudes.) The result is the net force (or resultant force) acting on the particle.

Although the vector nature of the forces makes the homework problems harder than if we simply had scalars, be thankful that Eq. 21-7 works. If two force vectors did not simply add but for some reason amplified each other, the world would be very difficult to understand and manage.

**Shell Theories.** Analogous to the shell theories for the gravitational force (Module 13-1), we have two shell theories for the electrostatic force:

- **Shell theory 1.** A charged particle outside a shell with charge uniformly distributed on its surface is attracted or repelled as if the shell’s charge were concentrated as a particle at its center.

- **Shell theory 2.** A charged particle inside a shell with charge uniformly distributed on its surface has no net force acting on it due to the shell.

(In the first theory, we assume that the charge on the shell is much greater than the particle’s charge. Thus the presence of the particle has negligible effect on the distribution of charge on the shell.)

**Spherical Conductors**

If excess charge is placed on a spherical shell that is made of conducting material, the excess charge spreads uniformly over the (external) surface. For example, if we place excess electrons on a spherical metal shell, those electrons repel one another and tend to move apart, spreading over the available surface until they are uniformly distributed. That arrangement maximizes the distances between all pairs of the excess electrons. According to the first shell theorem, the shell then will attract or repel an external charge as if all the excess charge on the shell were concentrated at its center.

If we remove negative charge from a spherical metal shell, the resulting positive charge of the shell is also spread uniformly over the surface of the shell. For example, if we remove \( n \) electrons, there are then \( n \) sites of positive charge (sites missing an electron) that are spread uniformly over the shell. According to the first shell theorem, the shell will again attract or repel an external charge as if all the shell’s excess charge were concentrated at its center.

**Checkpoint 2**

The figure shows two protons (symbol \( p \)) and one electron (symbol \( e \)) on an axis. On the central proton, what is the direction of (a) the force due to the electron, (b) the force due to the other proton, and (c) the net force?
Sample Problem 21.01 Finding the net force due to two other particles

This sample problem actually contains three examples, to build from basic stuff to harder stuff. In each we have the same charged particle 1. First there is a single force acting on it (easy stuff). Then there are two forces, but they are just in opposite directions (not too bad). Then there are again two forces but they are in very different directions (ah, now we have to get serious about the fact that they are vectors). The key to all three examples is to draw the forces correctly before you reach for a calculator, otherwise you may be calculating nonsense on the calculator. (Figure 21-7 is available in WileyPLUS as an animation with voiceover.)

(a) Figure 21-7a shows two positively charged particles fixed in place on an $x$ axis. The charges are $q_1 = 1.60 \times 10^{-19}$ C and $q_2 = 3.20 \times 10^{-19}$ C, and the particle separation is $R = 0.0200$ m. What are the magnitude and direction of the electrostatic force $F_{12}$ on particle 1 from particle 2?

**KEY IDEAS**

Because both particles are positively charged, particle 1 is repelled by particle 2, with a force magnitude given by Eq. 21-4. Thus, the direction of force $F_{12}$ on particle 1 is away from particle 2, in the negative direction of the $x$ axis, as indicated in the free-body diagram of Fig. 21-7b.

**Two particles:** Using Eq. 21-4 with separation $R$ substituted for $r$, we can write the magnitude $F_{12}$ of this force as

$$F_{12} = \frac{1}{4\pi\varepsilon_0} \frac{|q_1||q_2|}{R^2}$$

$$= (8.99 \times 10^9 \text{ N}\cdot\text{m}^2/\text{C}^2) \times \frac{(1.60 \times 10^{-19} \text{ C})(3.20 \times 10^{-19} \text{ C})}{(0.0200 \text{ m})^2}$$

$$= 1.15 \times 10^{-24} \text{ N}.$$

Thus, force $F_{12}$ has the following magnitude and direction (relative to the positive direction of the $x$ axis):

$$1.15 \times 10^{-24} \text{ N} \quad \text{and} \quad 180^\circ. \quad \text{Answer}$$

We can also write $F_{12}$ in unit-vector notation as

$$F_{12} = -\left(1.15 \times 10^{-24} \text{ N}\right)\hat{i}. \quad \text{Answer}$$

(b) Figure 21-7c is identical to Fig. 21-7a except that particle 3 now lies on the $x$ axis between particles 1 and 2. Particle 3 has charge $q_3 = -3.20 \times 10^{-19}$ C and is at a distance $\frac{3}{4}R$ from particle 1. What is the net electrostatic force $F_{1,\text{net}}$ on particle 1 due to particles 2 and 3?

**KEY IDEA**

The presence of particle 3 does not alter the electrostatic force on particle 1 from particle 2. Thus, force $F_{12}$ still acts on particle 1. Similarly, the force $F_{13}$ that acts on particle 1 due to particle 3 is not affected by the presence of particle 2. Because particles 1

![Figure 21-7](image-url)
and 3 have charge of opposite signs, particle 1 is attracted to particle 3. Thus, force $\vec{F}_{13}$ is directed toward particle 3, as indicated in the free-body diagram of Fig. 21-7d.

**Three particles:** To find the magnitude of $\vec{F}_{13}$, we can rewrite Eq. 21-4 as

$$F_{13} = \frac{1}{4\pi\varepsilon_0} \frac{|q_1||q_3|}{(\frac{q_1}{R})^2}$$

$$= \left(8.99 \times 10^{-9} \text{ N} \cdot \text{m}^2/\text{C}^2\right) \times \left(\frac{1.60 \times 10^{-19} \text{ C}}{0.0200 \text{ m}}\right)^2$$

$$= 2.05 \times 10^{-24} \text{ N}.$$  

We can also write $\vec{F}_{13}$ in unit-vector notation:

$$\vec{F}_{13} = (2.05 \times 10^{-24} \text{ N})\hat{i}.$$  

The net force $\vec{F}_{1,\text{net}}$ on particle 1 is the vector sum of $\vec{F}_{12}$ and $\vec{F}_{13}$; that is, from Eq. 21-7, we can write the net force $\vec{F}_{1,\text{net}}$ on particle 1 in unit-vector notation as

$$\vec{F}_{1,\text{net}} = \vec{F}_{12} + \vec{F}_{13}$$

$$= -(1.15 \times 10^{-24} \text{ N})\hat{i} + (2.05 \times 10^{-24} \text{ N})\hat{j}$$

$$= (9.00 \times 10^{-25} \text{ N})\hat{i}. \quad \text{(Answer)}$$

Thus, $\vec{F}_{1,\text{net}}$ has the following magnitude and direction (relative to the positive direction of the $x$ axis):

$$9.00 \times 10^{-25} \text{ N} \quad \text{and} \quad 0^\circ. \quad \text{(Answer)}$$

(c) Figure 21-7e is identical to Fig. 21-7a except that particle 4 is now included. It has charge $q_4 = -3.20 \times 10^{-19} \text{ C}$, is at a distance $\frac{3}{4}R$ from particle 1, and lies on a line that makes an angle $\theta = 60^\circ$ with the $x$ axis. What is the net electrostatic force $\vec{F}_{1,\text{net}}$ on particle 1 due to particles 2 and 4?

**KEY IDEA**

The net force $\vec{F}_{1,\text{net}}$ is the vector sum of $\vec{F}_{12}$ and a new force $\vec{F}_{14}$ acting on particle 1 due to particle 4. Because particles 1 and 4 have charge of opposite signs, particle 1 is attracted to particle 4. Thus, force $\vec{F}_{14}$ on particle 1 is directed toward particle 4, at angle $\theta = 60^\circ$, as indicated in the free-body diagram of Fig. 21-7f.

**Four particles:** We can rewrite Eq. 21-4 as

$$F_{14} = \frac{1}{4\pi\varepsilon_0} \frac{|q_1||q_4|}{(\frac{q_1}{R})^2}$$

$$= \left(8.99 \times 10^{-9} \text{ N} \cdot \text{m}^2/\text{C}^2\right) \times \left(\frac{1.60 \times 10^{-19} \text{ C}}{0.0200 \text{ m}}\right)^2$$

$$= 2.05 \times 10^{-24} \text{ N}.$$  

Then from Eq. 21-7, we can write the net force $\vec{F}_{1,\text{net}}$ on particle 1 as

$$\vec{F}_{1,\text{net}} = \vec{F}_{12} + \vec{F}_{14}.$$  

Because the forces $\vec{F}_{12}$ and $\vec{F}_{14}$ are not directed along the same axis, we cannot sum simply by combining their magnitudes. Instead, we must add them as vectors, using one of the following methods.

**Method 1. Summing directly on a vector-capable calculator.** For $\vec{F}_{12}$, we enter the magnitude $1.15 \times 10^{-24}$ and the angle $180^\circ$. For $\vec{F}_{14}$, we enter the magnitude $2.05 \times 10^{-24}$ and the angle $60^\circ$. Then we add the vectors.

**Method 2. Summing in unit-vector notation.** First we rewrite $\vec{F}_{14}$ as

$$\vec{F}_{14} = (F_{14} \cos \theta)\hat{i} + (F_{14} \sin \theta)\hat{j}.$$  

Substituting $2.05 \times 10^{-24} \text{ N}$ for $F_{14}$ and $60^\circ$ for $\theta$, this becomes

$$\vec{F}_{14} = (1.025 \times 10^{-24} \text{ N})\hat{i} + (1.775 \times 10^{-24} \text{ N})\hat{j}.$$  

Then we sum:

$$\vec{F}_{1,\text{net}} = \vec{F}_{12} + \vec{F}_{14}$$

$$= -(1.15 \times 10^{-24} \text{ N})\hat{i} + (2.05 \times 10^{-24} \text{ N})\hat{j}$$

$$+ (1.025 \times 10^{-24} \text{ N})\hat{i} + (1.775 \times 10^{-24} \text{ N})\hat{j}$$

$$= -(1.25 \times 10^{-24} \text{ N})\hat{i} + (1.78 \times 10^{-24} \text{ N})\hat{j}. \quad \text{(Answer)}$$

**Method 3. Summing components axis by axis.** The sum of the $x$ components gives us

$$F_{1,\text{net},x} = F_{12,x} + F_{14,x} = F_{12} + F_{14} \cos 60^\circ$$

$$= -1.15 \times 10^{-24} \text{ N} + (2.05 \times 10^{-24} \text{ N})(\cos 60^\circ)$$

$$= -1.25 \times 10^{-25} \text{ N}.$$  

The sum of the $y$ components gives us

$$F_{1,\text{net},y} = F_{12,y} + F_{14,y} = 0 + F_{14} \sin 60^\circ$$

$$= (2.05 \times 10^{-24} \text{ N})(\sin 60^\circ)$$

$$= 1.78 \times 10^{-24} \text{ N}.$$  

The net force $\vec{F}_{1,\text{net}}$ has the magnitude

$$F_{1,\text{net}} = \sqrt{F_{1,\text{net},x}^2 + F_{1,\text{net},y}^2} = 1.78 \times 10^{-24} \text{ N}. \quad \text{(Answer)}$$

To find the direction of $\vec{F}_{1,\text{net}}$, we take

$$\theta = \tan^{-1} \frac{F_{1,\text{net},y}}{F_{1,\text{net},x}} = -86.0^\circ.$$  

However, this is an unreasonable result because $\vec{F}_{1,\text{net}}$ must have a direction between the directions of $\vec{F}_{12}$ and $\vec{F}_{14}$. To correct $\theta$, we add $180^\circ$, obtaining

$$-86.0^\circ + 180^\circ = 94.0^\circ. \quad \text{(Answer)}$$
Checkpoints

The figure here shows three arrangements of an electron e and two protons p. (a) Rank the arrangements according to the magnitude of the net electrostatic force on the electron due to the protons, largest first. (b) In situation c, is the angle between the net force on the electron and the line labeled $d$ less than or more than $45^\circ$?

Sample Problem 21.02 Equilibrium of two forces on a particle

Figure 21-8a shows two particles fixed in place: a particle of charge $q_1 = +8q$ at the origin and a particle of charge $q_2 = -2q$ at $x = L$. At what point (other than infinitely far away) can a proton be placed so that it is in equilibrium (the net force on it is zero)? Is that equilibrium stable or unstable? (That is, if the proton is displaced, do the forces drive it back to the point of equilibrium or drive it farther away?)

Key Idea

If $\vec{F}_1$ is the force on the proton due to charge $q_1$ and $\vec{F}_2$ is the force on the proton due to charge $q_2$, then the point we seek is where $\vec{F}_1 + \vec{F}_2 = 0$. Thus,

$$\vec{F}_1 = -\vec{F}_2. \quad (21-8)$$

This tells us that at the point we seek, the forces acting on the proton due to the other two particles must be of equal magnitudes,

$$F_1 = F_2. \quad (21-9)$$

and that the forces must have opposite directions.

Reasoning: Because a proton has a positive charge, the proton and the particle of charge $q_1$ are of the same sign, and force $\vec{F}_1$ on the proton must point away from $q_1$. Also, the proton and the particle of charge $q_2$ are of opposite signs, so force $\vec{F}_2$ on the proton must point toward $q_2$. “Away from $q_1$” and “toward $q_2$” can be in opposite directions only if the proton is located on the $x$ axis.

If the proton is on the $x$ axis at any point between $q_1$ and $q_2$, such as point $P$ in Fig. 21-8b, then $\vec{F}_1$ and $\vec{F}_2$ are in the same direction and not in opposite directions as required. If the proton is at any point on the $x$ axis to the left of $q_1$, such as point $S$ in Fig. 21-8c, then $\vec{F}_1$ and $\vec{F}_2$ are in opposite directions. However, Eq. 21-4 tells us that $\vec{F}_1$ and $\vec{F}_2$ cannot have equal magnitudes there: $F_1$ must be greater than $F_2$, because $F_1$ is produced by a closer charge (with lesser $r$) of greater magnitude ($8q$ versus $2q$).

Finally, if the proton is at any point on the $x$ axis to the right of $q_2$, such as point $R$ in Fig. 21-8d, then $\vec{F}_1$ and $\vec{F}_2$ are again in opposite directions. However, because now the charge of greater magnitude ($q_1$) is farther away from the proton than the charge of lesser magnitude, there is a point at which $F_1$ is equal to $F_2$. Let $x$ be the coordinate of this point, and let $q_p$ be the charge of the proton.

Calculations: With Eq. 21-4, we can now rewrite Eq. 21-9:

$$\frac{1}{4\pi\varepsilon_0} \frac{8qq_p}{x^2} = \frac{1}{4\pi\varepsilon_0} \frac{2qq_p}{(x-L)^2}. \quad (21-10)$$

(Note that only the charge magnitudes appear in Eq. 21-10. We already decided about the directions of the forces in drawing Fig. 21-8d and do not want to include any positive or negative signs here.) Rearranging Eq. 21-10 gives us

$$\left(\frac{x-L}{x}\right)^2 = \frac{1}{4}.\quad \text{(Answer)}$$

After taking the square roots of both sides, we find

$$\frac{x-L}{x} = \frac{1}{2}$$

and

$$x = 2L.$$
Sample Problem 21.03  Charge sharing by two identical conducting spheres

In Fig. 21-9a, two identical, electrically isolated conducting spheres $A$ and $B$ are separated by a (center-to-center) distance $a$ that is large compared to the spheres. Sphere $A$ has a positive charge of $+Q$, and sphere $B$ is electrically neutral. Initially, there is no electrostatic force between the spheres. (The large separation means there is no induced charge.)

(a) Suppose the spheres are connected for a moment by a conducting wire. The wire is thin enough so that any net charge on it is negligible. What is the electrostatic force between the spheres after the wire is removed?

**KEY IDEAS**

1. Because the spheres are identical, connecting them means that they end up with identical charges (same sign and same amount). (2) The initial sum of the charges (including the signs of the charges) must equal the final sum of the charges.

**Reasoning:** When the spheres are wired together, the (negative) conduction electrons on $B$, which repel one another, have a way to move away from one another (along the wire to positively charged $A$, which attracts them—Fig. 21-9b). As $B$ loses negative charge, it becomes positively charged, and as $A$ gains negative charge, it becomes less positively charged. The transfer of charge stops when the charge on $B$ has increased to $+Q/2$ and the charge on $A$ has decreased to $+Q/2$, which occurs when $-Q/2$ has shifted from $B$ to $A$.

After the wire has been removed (Fig. 21-9c), we can assume that the charge on either sphere does not disturb the uniformity of the charge distribution on the other sphere, because the spheres are small relative to their separation. Thus, we can apply the first shell theorem to each sphere. By Eq. 21-4 with $q_1 = q_2 = Q/2$ and $r = a$,

\[
F = \frac{1}{4\pi\varepsilon_0} \frac{(Q/2)(Q/2)}{a^2} = \frac{1}{16\pi\varepsilon_0} \left(\frac{Q}{a}\right)^2. \quad \text{(Answer)}
\]

The spheres, now positively charged, repel each other.

(b) Next, suppose sphere $A$ is grounded momentarily, and then the ground connection is removed. What now is the electrostatic force between the spheres?

**Reasoning:** When we provide a conducting path between a charged object and the ground (which is a huge conductor), we neutralize the object. Were sphere $A$ negatively charged, the mutual repulsion between the excess electrons would cause them to move from the sphere to the ground. However, because sphere $A$ is positively charged, electrons with a total charge of $-Q/2$ move from the ground up onto the sphere (Fig. 21-9d), leaving the sphere with a charge of 0 (Fig. 21-9e). Thus, the electrostatic force is again zero.

Additional examples, video, and practice available at WileyPLUS

# 21-2 CHARGE IS QUANTIZED

**Learning Objectives**

*After reading this module, you should be able to . . .

21.19 Identify the elementary charge.

21.20 Identify that the charge of a particle or object must be a positive or negative integer times the elementary charge.

**Key Ideas**

- Electric charge is quantized (restricted to certain values).
- The charge of a particle can be written as $ne$, where $n$ is a positive or negative integer and $e$ is the elementary charge, which is the magnitude of the charge of the electron and proton ($\approx 1.602 \times 10^{-19}$ C).

**Charge Is Quantized**

In Benjamin Franklin’s day, electric charge was thought to be a continuous fluid—an idea that was useful for many purposes. However, we now know that
Table 21-1  The Charges of Three Particles

<table>
<thead>
<tr>
<th>Particle</th>
<th>Symbol</th>
<th>Charge</th>
</tr>
</thead>
<tbody>
<tr>
<td>Electron</td>
<td>e or e(^-)</td>
<td>(-e)</td>
</tr>
<tr>
<td>Proton</td>
<td>p</td>
<td>(+e)</td>
</tr>
<tr>
<td>Neutron</td>
<td>n</td>
<td>0</td>
</tr>
</tbody>
</table>

Fluids themselves, such as air and water, are not continuous but are made up of atoms and molecules; matter is discrete. Experiment shows that “electrical fluid” is also not continuous but is made up of multiples of a certain elementary charge. Any positive or negative charge \(q\) that can be detected can be written as

\[
q = ne, \quad n = \pm 1, \pm 2, \pm 3, \ldots,
\]

in which \(e\), the elementary charge, has the approximate value

\[
e = 1.602 \times 10^{-19} \text{ C}.
\]

The elementary charge \(e\) is one of the important constants of nature. The electron and proton both have a charge of magnitude \(e\) (Table 21-1). (Quarks, the constituent particles of protons and neutrons, have charges of \(\pm e/3\) or \(\pm 2e/3\), but they apparently cannot be detected individually. For this and for historical reasons, we do not take their charges to be the elementary charge.)

You often see phrases—such as “the charge on a sphere,” “the amount of charge transferred,” and “the charge carried by the electron”—that suggest that charge is a substance. (Indeed, such statements have already appeared in this chapter.) You should, however, keep in mind what is intended: Particles are the substance and charge happens to be one of their properties, just as mass is.

When a physical quantity such as charge can have only discrete values rather than any value, we say that the quantity is quantized. It is possible, for example, to find a particle that has no charge at all or a charge of \(+10e\) or \(−6e\), but not a particle with a charge of, say, \(3.57e\).

The quantum of charge is small. In an ordinary 100 W lightbulb, for example, about \(10^{19}\) elementary charges enter the bulb every second and just as many leave. However, the graininess of electricity does not show up in such large-scale phenomena (the bulb does not flicker with each electron).

Checkpointer 4

Initially, sphere \(A\) has a charge of \(-50e\) and sphere \(B\) has a charge of \(+20e\). The spheres are made of conducting material and are identical in size. If the spheres then touch, what is the resulting charge on sphere \(A\)?

Sample Problem 21.04  Mutual electric repulsion in a nucleus

The nucleus in an iron atom has a radius of about \(4.0 \times 10^{-15} \text{ m}\) and contains 26 protons.

(a) What is the magnitude of the repulsive electrostatic force between two of the protons that are separated by \(4.0 \times 10^{-15} \text{ m}\)?

**KEY IDEA**

The protons can be treated as charged particles, so the magnitude of the electrostatic force on one from the other is given by Coulomb’s law.

**Calculation:** Table 21-1 tells us that the charge of a proton is \(+e\). Thus, Eq. 21-4 gives us

\[
F = \frac{1}{4\pi\varepsilon_0} \frac{e^2}{r^2} = \frac{(8.99 \times 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2)(1.602 \times 10^{-19} \text{ C})^2}{(4.0 \times 10^{-15} \text{ m})^2} = 14 \text{ N}.
\]

No explosion: This is a small force to be acting on a macroscopic object like a cantaloupe, but an enormous force to be acting on a proton. Such forces should explode the nucleus of any element but hydrogen (which has only one proton in its nucleus). However, they don’t, not even in nuclei with a great many protons. Therefore, there must be some enormous attractive force to counter this enormous repulsive electrostatic force.

(b) What is the magnitude of the gravitational force between those same two protons?

**KEY IDEA**

Because the protons are particles, the magnitude of the gravitational force on one from the other is given by Newton’s equation for the gravitational force (Eq. 21-2).

**Calculation:** With \(m_p (= 1.67 \times 10^{-27} \text{ kg})\) representing the
mass of a proton, Eq. 21-2 gives us

\[ F = \frac{G m^2}{r^2} = \frac{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2)(1.67 \times 10^{-27} \text{ kg})^2}{(4.0 \times 10^{-15} \text{ m})^2} = 1.2 \times 10^{-35} \text{ N}. \]  

\text{(Answer)}

**Weak versus strong:** This result tells us that the (attractive) gravitational force is far too weak to counter the repulsive electrostatic forces between protons in a nucleus. Instead, the protons are bound together by an enormous force called (aptly) the \textit{strong nuclear force}— a force that acts between protons (and neutrons) when they are close together, as in a nucleus.

Although the gravitational force is many times weaker than the electrostatic force, it is more important in large-scale situations because it is always attractive. This means that it can collect many small bodies into huge bodies with huge masses, such as planets and stars, that then exert large gravitational forces. The electrostatic force, on the other hand, is repulsive for charges of the same sign, so it is unable to collect either positive charge or negative charge into large concentrations that would then exert large electrostatic forces.

---

21-3 **CHARGE IS CONSERVED**

**Learning Objectives**

After reading this module, you should be able to . . .

- **21.21** Identify that in any isolated physical process, the net charge cannot change (the net charge is always conserved).
- **21.22** Identify an annihilation process of particles and a pair production of particles.
- **21.23** Identify mass number and atomic number in terms of the number of protons, neutrons, and electrons.

**Key Ideas**

- The net electric charge of any isolated system is always conserved.
- If two charged particles undergo an annihilation process, they have opposite signs of charge.
- If two charged particles appear as a result of a pair production process, they have opposite signs of charge.

**Charge Is Conserved**

If you rub a glass rod with silk, a positive charge appears on the rod. Measurement shows that a negative charge of equal magnitude appears on the silk. This suggests that rubbing does not create charge but only transfers it from one body to another, upsetting the electrical neutrality of each body during the process. This hypothesis of \textit{conservation of charge}, first put forward by Benjamin Franklin, has stood up under close examination, both for large-scale charged bodies and for atoms, nuclei, and elementary particles. No exceptions have ever been found. Thus, we add electric charge to our list of quantities—including energy and both linear momentum and angular momentum—that obey a conservation law.

Important examples of the conservation of charge occur in the \textit{radioactive decay} of nuclei, in which a nucleus transforms into (becomes) a different type of nucleus. For example, a uranium-238 nucleus \((^{238}\text{U})\) transforms into a thorium-234 nucleus \((^{234}\text{Th})\) by emitting an \textit{alpha particle}. Because that particle has the same makeup as a helium-4 nucleus, it has the symbol \(^4\text{He}\). The number used in the name of a nucleus and as a superscript in the symbol for the nucleus is called the \textit{mass number} and is the total number of the protons and neutrons in the nucleus. For example, the total number in \(^{238}\text{U}\) is 238. The number of protons in a nucleus is the \textit{atomic number} \(Z\), which is listed for all the elements in Appendix F. From that list we find that in the decay

\[
^{238}\text{U} \rightarrow ^{234}\text{Th} + ^4\text{He},
\]  

(21-13)
the parent nucleus $^{238}\text{U}$ contains 92 protons (a charge of $+92e$), the daughter nucleus $^{234}\text{Th}$ contains 90 protons (a charge of $+90e$), and the emitted alpha particle $^4\text{He}$ contains 2 protons (a charge of $+2e$). We see that the total charge is $+92e$ before and after the decay; thus, charge is conserved. (The total number of protons and neutrons is also conserved: 238 before the decay and $234 + 4 = 238$ after the decay.)

Another example of charge conservation occurs when an electron $e^-$ (charge $-e$) and its antiparticle, the positron $e^+$ (charge $+e$), undergo an annihilation process, transforming into two gamma rays (high-energy light):

$$e^- + e^+ \rightarrow \gamma + \gamma \quad (\text{annihilation}). \quad (21-14)$$

In applying the conservation-of-charge principle, we must add the charges algebraically, with due regard for their signs. In the annihilation process of Eq. 21-14 the net charge of the system is zero both before and after the event. Charge is conserved.

In pair production, the converse of annihilation, charge is also conserved. In this process a gamma ray transforms into an electron and a positron:

$$\gamma \rightarrow e^- + e^+ \quad (\text{pair production}). \quad (21-15)$$

Figure 21-10 shows such a pair-production event that occurred in a bubble chamber. (This is a device in which a liquid is suddenly made hotter than its boiling point. If a charged particle passes through it, tiny vapor bubbles form along the particle’s trail.) A gamma ray entered the chamber from the bottom and at one point transformed into an electron and a positron. Because those new particles were charged and moving, each left a trail of bubbles. (The trails were curved because a magnetic field had been set up in the chamber.) The gamma ray, being electrically neutral, left no trail. Still, you can tell exactly where it underwent pair production—at the tip of the curved $V$, which is where the trails of the electron and positron begin.

### Review & Summary

**Electric Charge**  The strength of a particle’s electrical interaction with objects around it depends on its electric charge (usually represented as $q$), which can be either positive or negative. Particles with the same sign of charge repel each other, and particles with opposite signs of charge attract each other. An object with equal amounts of the two kinds of charge is electrically neutral, whereas one with an imbalance is electrically charged and has an excess charge.

**Conductors** are materials in which a significant number of electrons are free to move. The charged particles in nonconductors (insulators) are not free to move.

Electric current $I$ is the rate $dq/dt$ at which charge passes a point:

$$I = \frac{dq}{dt} \quad \text{(electric current)}. \quad (21-3)$$

**Coulomb’s Law**  Coulomb’s law describes the electrostatic force (or electric force) between two charged particles. If the particles have charges $q_1$ and $q_2$, are separated by distance $r$, and are at rest (or moving only slowly) relative to each other, then the magnitude of the force acting on each due to the other is given by

$$F = \frac{1}{4\pi\varepsilon_0} \frac{|q_1| |q_2|}{r^2} \quad \text{(Coulomb’s law)}. \quad (21-4)$$

where $\varepsilon_0 = 8.85 \times 10^{-12} \text{F/m}$ is the permittivity constant. The ratio $1/4\pi\varepsilon_0$ is often replaced with the electrostatic constant (or Coulomb constant) $k = 8.99 \times 10^9 \text{N}\cdot\text{m}^2/\text{C}^2$.

The electrostatic force vector acting on a charged particle due to a second charged particle is either directly toward the second particle (opposite signs of charge) or directly away from it (same sign of charge). As with other types of forces, if multiple electrostatic forces act on a particle, the net force is the vector sum (not scalar sum) of the individual forces.

The two shell theories for electrostatics are

**Shell theorem 1:** A charged particle outside a shell with charge uniformly distributed on its surface is attracted or repelled as if the shell’s charge were concentrated as a particle at its center.

**Shell theorem 2:** A charged particle inside a shell with charge uniformly distributed on its surface has no net force acting on it due to the shell.

Charge on a conducting spherical shell spreads uniformly over the (external) surface.

**The Elementary Charge**  Electric charge is quantized (restricted to certain values). The charge of a particle can be written as $ne$, where $n$ is a positive or negative integer and $e$ is the elementary charge, which is the magnitude of the charge of the electron and proton ($= 1.602 \times 10^{-19} \text{C}$).

**Conservation of Charge**  The net electric charge of any isolated system is always conserved.
1. Figure 21-11 shows four situations in which five charged particles are evenly spaced along an axis. The charge values are indicated except for the central particle, which has the same charge in all four situations. Rank the situations according to the magnitude of the net electrostatic force on the central particle, greatest first.

2. Figure 21-12 shows three pairs of identical spheres that are to be touched together and then separated. The initial charges on them are indicated. Rank the pairs according to (a) the magnitude of the charge transferred during touching and (b) the charge left on the positively charged sphere, greatest first.

3. Figure 21-13 shows four situations in which charged particles are fixed in place on an axis. In which situations is there a point to the left of the first two particles where an electron will be in equilibrium?

4. Figure 21-14 shows two charged particles on an axis. The charges are free to move. However, a third charged particle can be placed at a certain point such that all three particles are then in equilibrium. (a) Is that point to the left of the first two particles, to their right, or between them? (b) Should the third particle be positively or negatively charged? (c) Is the equilibrium stable or unstable?

5. In Fig. 21-15, a central particle of charge \(-q\) is surrounded by two circular rings of charged particles. What are the magnitude and direction of the net electrostatic force on the central particle due to the other particles? (Hint: Consider symmetry.)

6. A positively charged ball is brought close to an electrically neutral isolated conductor. The conductor is then grounded while the ball is kept close. Is the conductor charged positively, charged negatively, or neutral if (a) the ball is first taken away and then the ground connection is removed and (b) the ground connection is first removed and then the ball is taken away?

7. Figure 21-16 shows three situations involving a charged particle and a uniformly charged spherical shell. The charges are given, and the radii of the shells are indicated. Rank the situations according to the magnitude of the force on the particle due to the presence of the shell, greatest first.

8. Figure 21-17 shows four arrangements of charged particles. Rank the arrangements according to the magnitude of the net electrostatic force on the particle with charge \(+Q\), greatest first.

9. Figure 21-18 shows four situations in which particles of charge \(+q\) or \(-q\) are fixed in place. In each situation, the parti-
icles on the x axis are equidistant from the y axis. First, consider the middle particle in situation 1; the middle particle experiences an electrostatic force from each of the other two particles. 

(a) Are the magnitudes \( F \) of those forces the same or different? 
(b) Is the magnitude of the net force on the middle particle equal to, greater than, or less than \( 2F \)? 
(c) Do the x components of the two forces add or cancel? 
(d) Do their y components add or cancel? 
(e) Is the direction of the net force on the middle particle that of the canceling components or the adding components? 
(f) What is the direction of that net force? Now consider the remaining situations: What is the direction of the net force on the middle particle in (g) situation 2, (h) situation 3, and (i) situation 4? (In each situation, consider the symmetry of the charge distribution and determine the canceling components and the adding components.)

10 In Fig. 21-19, a central particle of charge \(-2q\) is surrounded by a square array of charged particles, separated by either distance \( d \) or \( d/2 \) along the perimeter of the square. What are the magnitude and direction of the net electrostatic force on the central particle due to the other particles? (Hint: Consideration of symmetry can greatly reduce the amount of work required here.)

11 Figure 21-20 shows three identical conducting bubbles \( \text{A}, \text{B}, \text{and C} \) floating in a conducting container that is grounded by a wire. The bubbles initially have the same charge. Bubble \( \text{A} \) bumps into the container’s ceiling and then into bubble \( \text{B} \). Then bubble \( \text{B} \) bumps into bubble \( \text{C} \), which then drifts to the container’s floor. When bubble \( \text{C} \) reaches the floor, a charge of \(-3e\) is transferred upward through the wire, from the ground to the container, as indicated. 

(a) What was the initial charge of each bubble? 
(b) When \( \text{bubble A} \) and (c) \( \text{bubble B} \) reach the floor, what is the charge transfer through the wire? 
(d) During this whole process, what is the total charge transfer through the wire?

12 Figure 21-21 shows four situations in which a central proton is partially surrounded by protons or electrons fixed in place along a half-circle. The angles \( \theta \) are identical; the angles \( \phi \) are also. 

(a) In each situation, what is the direction of the net force on the central proton due to the other particles? 
(b) Rank the four situations according to the magnitude of that net force on the central proton, greatest first.

---

Problems

1. **Module 21-1 Coulomb’s Law**

- **SSM ILW** Of the charge \( Q \) initially on a tiny sphere, a portion \( q \) is to be transferred to a second, nearby sphere. Both spheres can be treated as particles and are fixed with a certain separation. For what value of \( q/Q \) will the electrostatic force between the two spheres be maximized?
2. Identical isolated conducting spheres 1 and 2 have equal charges and are separated by a distance that is large compared with their diameters (Fig. 21-22a). The electrostatic force acting on sphere 2 due to sphere 1 is \( F \). Suppose now that a third identical sphere 3, having an insulating handle and initially neutral, is touched first to sphere 1 (Fig. 21-22b), then to sphere 2 (Fig. 21-22c), and finally removed (Fig. 21-22d). The electrostatic force that now acts on sphere 2 has magnitude \( F' \). What is the ratio \( F' / F \)?

![Figure 21-22 Problem 2.](image)

3. SSM What must be the distance between point charge \( q_1 = 26.0 \, \mu \text{C} \) and point charge \( q_2 = -47.0 \, \mu \text{C} \) for the electrostatic force between them to have a magnitude of 5.70 N?

4. In the return stroke of a typical lightning bolt, a current of \( 2.5 \times 10^4 \, \text{A} \) exists for 20 \( \mu \text{s} \). How much charge is transferred in this event?

5. A particle of charge +3.00 \( \times 10^{-6} \, \text{C} \) is 12.0 cm distant from a second particle of charge \( -1.50 \times 10^{-6} \, \text{C} \). Calculate the magnitude of the electrostatic force between the particles.

6. ILW Two equally charged particles are held 3.2 \( \times 10^{-3} \, \text{m} \) apart and then released from rest. The initial acceleration of the first particle is observed to be 7.0 m/s\(^2\) and that of the second to be 9.0 m/s\(^2\). If the mass of the first particle is 6.3 \( \times 10^{-7} \, \text{kg} \), what are (a) the mass of the second particle and (b) the magnitude of the charge of each particle?

7. In Fig. 21-23, three charged particles lie on an \( x \) axis. Particles 1 and 2 are fixed in place. Particle 3 is free to move, but the net electrostatic force on it from particles 1 and 2 happens to be zero. If \( L_{23} = L_{12} \), what is the ratio \( q_1 / q_2 \)?

![Figure 21-23 Problems 7 and 40.](image)

8. In Fig. 21-24, three identical conducting spheres initially have the following charges: sphere A, 4\( Q \); sphere B, –6\( Q \); and sphere C, 0. Spheres A and B are fixed in place, with a center-to-center separation that is much larger than the spheres. Two experiments are conducted. In experiment 1, sphere C is touched to sphere A and then (separately) to sphere B, and then it is removed. In experiment 2, starting with the same initial states, the procedure is reversed: Sphere C is touched to sphere B and then (separately) to sphere A, and then it is removed. What is the ratio of the electrostatic force between A and B at the end of experiment 2 to that at the end of experiment 1?

![Figure 21-24 Problems 8 and 65.](image)

9. SSM, WWW Two identical conducting spheres, fixed in place, attract each other with an electrostatic force of 0.108 N when their center-to-center separation is 50.0 cm. The spheres are then connected by a thin conducting wire. When the wire is removed, the spheres repel each other with an electrostatic force of 0.0360 N. Of the initial charges on the spheres, with a positive net charge, what was (a) the negative charge on one of them and (b) the positive charge on the other?

10. In Fig. 21-25, four particles form a square. The charges are \( q_1 = q_4 = Q \) and \( q_2 = q_3 = q \). (a) What is \( Q/q \) if the net electrostatic force on particles 1 and 4 is zero? (b) Is there any value of \( q \) that makes the net electrostatic force on each of the four particles zero? Explain.

11. ILW In Fig. 21-25, the particles have charges \( q_1 = -q_2 = 100 \, \text{nC} \) and \( q_3 = 200 \, \text{nC} \), and distance \( a = 5.0 \, \text{cm} \). What are the (a) \( x \) and (b) \( y \) components of the net electrostatic force on particle 3?

12. Two particles are fixed on an \( x \) axis. Particle 1 of charge 40 \( \mu \text{C} \) is located at \( x = -2.0 \, \text{cm} \); particle 2 of charge \( Q \) is located at \( x = 3.0 \, \text{cm} \). Particle 3 of charge magnitude \( 20 \, \mu \text{C} \) is released from rest on the \( y \) axis at \( y = 2.0 \, \text{cm} \). What is the value of \( Q \) if the initial acceleration of particle 3 is in the positive direction of (a) the \( x \) axis and (b) the \( y \) axis?

13. In Fig. 21-26, particle 1 of charge +1.0 \( \mu \text{C} \) and particle 2 of charge \( -3.0 \, \mu \text{C} \) are held at separation \( L = 10.0 \, \text{cm} \) on an \( x \) axis. If particle 3 of unknown charge \( q_3 \) is to be located such that the net electrostatic force on it from particles 1 and 2 is zero, what must be the (a) \( x \) and (b) \( y \) coordinates of particle 3?

![Figure 21-26 Problems 13, 19, 30, 58, and 67.](image)

14. Three particles are fixed on an \( x \) axis. Particle 1 of charge \( q_1 \) is at \( x = -a \), and particle 2 of charge \( q_2 \) is at \( x = +a \). If their net electrostatic force on particle 3 of charge \( +Q \) is to be zero, what must be the ratio \( q_1/q_2 \) when particle 3 is at (a) \( x = +0.500a \) and (b) \( x = +1.50a \)?

15. The charges and coordinates of two charged particles held fixed in an \( xy \) plane are \( q_1 = +3.0 \, \mu \text{C}, x_1 = 3.5 \, \text{cm}, y_1 = 0.50 \, \text{cm} \), and \( q_2 = -4.0 \, \mu \text{C}, x_2 = -2.0 \, \text{cm}, y_2 = 1.5 \, \text{cm} \). Find the (a) magnitude and (b) direction of the electrostatic force on particle 2 due to particle 1. At what (c) \( x \) and (d) \( y \) coordinates should a third particle of charge \( q_3 = +4.0 \, \mu \text{C} \) be placed such that the net electrostatic force on particle 2 due to particles 1 and 3 is zero?

16. In Fig. 21-27a, particle 1 (of charge \( q_1 \)) and particle 2 (of charge \( q_2 \)) are fixed in place on an \( x \) axis, 8.00 cm apart. Particle 3 (of
charge \(q_3 = +8.00 \times 10^{-19} \text{ C}\) is to be placed on the line between particles 1 and 2 so that they produce a net electrostatic force \(F_{3, \text{net}}\) on it. Figure 21-27b gives the \(x\) component of that force versus the coordinate \(x\) at which particle 3 is placed. The scale of the \(x\) axis is set by \(x_1 = 8.0\text{ cm}\). What are (a) the sign of charge \(q_1\), and (b) the ratio \(q_2/q_1\)?

**Problem 17.** In Fig. 21-28a, particles 1 and 2 have charge 20.0 \(\mu\text{C}\) each and are held at separation distance \(d = 1.50\text{ m}\). (a) What is the magnitude of the electrostatic force on particle 1 due to particle 2? In Fig. 21-28b, particle 3 of charge 20.0 \(\mu\text{C}\) is positioned so as to complete an equilateral triangle. (b) What is the magnitude of the net electrostatic force on particle 1 due to particles 2 and 3?

**Problem 18.** In Fig. 21-29a, three positively charged particles are fixed on an \(x\) axis. Particles \(B\) and \(C\) are so close to each other that they can be considered to be at the same distance from particle \(A\). The net force on particle \(A\) due to particles \(B\) and \(C\) is \(2.014 \times 10^{-23} \text{ N}\) in the negative direction of the \(x\) axis. In Fig. 21-29b, particle \(B\) has been moved to the opposite side of \(A\) but is still at the same distance from it. The net force on \(A\) is now \(2.877 \times 10^{-23} \text{ N}\) in the negative direction of the \(x\) axis. What is the ratio \(q_B/q_A\)?

**Problem 19.** In Fig. 21-26, particle 1 of charge \(+q\) and particle 2 of charge \(+4.00q\) are held at separation \(L = 9.00 \text{ cm}\) on an \(x\) axis. If particle 3 of charge \(q_3\) is to be located such that the three particles remain in place when released, what must be the (a) \(x\) and (b) \(y\) coordinates of particle 3, and (c) the ratio \(q_3/q\)?

**Problem 20.** Figure 21-30a shows an arrangement of three charged particles separated by distance \(d\). Particles \(A\) and \(C\) are fixed on the \(x\) axis, but particle \(B\) can be moved along a circle centered on particle \(A\). During the movement, a radial line between \(A\) and \(B\) makes an angle \(\theta\) relative to the positive direction of the \(x\) axis (Fig. 21-30b). The curves in Fig. 21-30c give, for two situations, the magnitude \(F_{\text{net}}\) of the net electrostatic force on particle \(A\) due to the other particles. That net force is given as a function of angle \(\theta\) and as a multiple of a basic amount \(F_0\). For example on curve 1, at \(\theta = 180^\circ\), we see that \(F_{\text{net}} = 2F_0\). (a) For the situation corresponding to curve 1, what is the ratio of the charge of particle \(C\) to that of particle \(B\) (including sign)? (b) For the situation corresponding to curve 2, what is that ratio?

**Module 21-2 Charge Is Quanized**

**Problem 24.** Two tiny, spherical water drops, with identical charges of \(-1.00 \times 10^{-16} \text{ C}\), have a center-to-center separation of 1.00 cm. (a) What is the magnitude of the electrostatic force acting between them? (b) How many excess electrons are on each drop, giving it its charge imbalance?

**Problem 25.** How many electrons would have to be removed from a coin to leave it with a charge of \(+1.0 \times 10^{-7} \text{ C}\)?

**Problem 26.** What is the magnitude of the electrostatic force between a singly charged sodium ion (\(\text{Na}^+\), of charge \(+e\)) and an adjacent singly charged chlorine ion (\(\text{Cl}^-\), of charge \(-e\)) in a salt crystal if their separation is \(2.82 \times 10^{-10} \text{ m}\)?

**Problem 27.** The magnitude of the electrostatic force between two identical ions that are separated by a distance of \(5.0 \times 10^{-10} \text{ m}\) is \(3.7 \times 10^{-9} \text{ N}\). (a) What is the charge of each ion? (b) How many electrons are “missing” from each ion (thus giving the ion its charge imbalance)?

**Problem 28.** A current of 0.300 A through your chest can send your heart into fibrillation, ruining the normal rhythm of heartbeat and disrupting the flow of blood (and thus oxygen) to your brain. If that current persists for 2.00 min, how many conduction electrons pass through your chest?

**Problem 29.** In Fig. 21-33, particles 2 and 4, of charge \(-e\), are fixed in place on a \(y\) axis, at \(y_2 = -10.0 \text{ cm}\) and \(y_4 = -20.0 \text{ cm}\). Figure 21-33 Problem 29.
and \( y_4 = 5.00 \text{ cm} \). Particles 1 and 3, of charge \(-e\), can be moved along the \( x \) axis. Particle 5, of charge \(+e\), is fixed at the origin. Initially particle 1 is at \( x_1 = -10.0 \text{ cm} \) and particle 3 is at \( x_3 = 10.0 \text{ cm} \). (a) At what coordinate should particle 3 be placed to minimize the electrostatic force on particle 2 due to particles 1 and 3? (b) With particle 1 fixed at its new position, to what \( x \) value must you move particle 3 to rotate back to its original direction?

**30** In Fig. 21-26, particles 1 and 2 are fixed in place on an \( x \) axis, at a separation of \( L = 8.00 \text{ cm} \). Their charges are \( q_1 = +e \) and \( q_2 = -27e \). Particle 3 with charge \( q_3 = +4e \) is to be placed on the line between particles 1 and 2, so that they produce a net electrostatic force \( \vec{F}_{3,\text{net}} \) on it. (a) At what coordinate should particle 3 be placed to minimize the magnitude of that force? (b) What is that minimum magnitude?

**31** Earth’s atmosphere is constantly bombarded by cosmic ray protons that originate somewhere in space. If the protons all passed through the atmosphere, each square meter of Earth’s surface would intercept protons at the average rate of 1500 protons per second. What would be the electric current intercepted by the total surface area of the planet?

**32** Figure 21-34a shows charged particles 1 and 2 that are fixed in place on an \( x \) axis. Particle 1 has a charge with a magnitude of \( |q_1| = 8.00e \). Particle 3 of charge \( q_3 = +8.00e \) is initially on the \( x \) axis near particle 2. Then particle 3 is gradually moved in the positive direction of the \( x \) axis. As a result, the magnitude of the net electrostatic force \( \vec{F}_{3,\text{net}} \) on particle 2 due to particles 1 and 3 changes. Figure 21-34b gives the \( x \) component of that net force as a function of the position \( x \) of particle 3. The scale of the \( x \) axis is set by \( x_1 = 0.80 \text{ m} \). The plot has an asymptote of \( F_{2,\text{net}} = 1.5 \times 10^{-25} \text{ N} \) as \( x \to \infty \). As a multiple of \( e \) and including the sign, what is the charge \( q_2 \) of particle 2?

**33** Calculate the number of coulombs of positive charge in 250 cm\(^3\) of (neutral) water. (Hint: A hydrogen atom contains one proton; an oxygen atom contains eight protons.)

**34** Figure 21-35 shows electrons 1 and 2 on an \( x \) axis and charged ions 3 and 4 of identical charge \(-q\) and at identical angles \( \theta \). Electron 2 is free to move; the other three particles are fixed in place at horizontal distances \( R \) from electron 2 and are intended to hold electron 2 in place. For physically possible values of \( q \leq 5e \), what are the (a) smallest, (b) second smallest, and (c) third smallest values of \( \theta \) for which electron 2 is held in place?

**35** In crystals of the salt cesium chloride, cesium ions Cs\(^+\) form the eight corners of a cube and a chlorine ion Cl\(^-\) is at the cube’s center (Fig. 21-36). The edge length of the cube is 0.40 nm. The Cs\(^+\) ions are each deficient by one electron (and thus each has a charge of \(+e\)), and the Cl\(^-\) ion has one excess electron (and thus has a charge of \(-e\)). (a) What is the magnitude of the net electrostatic force exerted on the Cl\(^-\) ion by the eight Cs\(^+\) ions at the corners of the cube? (b) If one of the Cs\(^+\) ions is missing, the crystal is said to have a defect; what is the magnitude of the net electrostatic force exerted on the Cl\(^-\) ion by the seven remaining Cs\(^+\) ions?

**Additional Problems**

**36** Electrons and positrons are produced by the nuclear transformations of protons and neutrons known as beta decay. (a) If a proton transforms into a neutron, is an electron or a positron produced? (b) If a neutron transforms into a proton, is an electron or a positron produced?

**37** Identify X in the following nuclear reactions: (a) \(^1\text{H} + ^9\text{Be} \rightarrow X + n\); (b) \(^1\text{H} \rightarrow X\); (c) \(^1\text{H} + ^5\text{N} \rightarrow ^4\text{He} + X\). Appendix F will help.

**38** Figure 21-37 shows four identical conducting spheres that are actually well separated from one another, Sphere W (with an initial charge of zero) is touched to sphere A and then they are separated. Next, sphere W is touched to sphere B (with an initial charge of \(-32e\)) and then they are separated. Finally, sphere W is touched to sphere C (with an initial charge of \(+48e\)), and they are separated. The final charge on sphere W is \(+18e\). What was the initial charge on sphere A?

**39** In Fig. 21-38, particle 1 of charge \(+4e\) is above a floor by distance \( d_1 = 2.00 \text{ mm} \) and particle 2 of charge \(+6e\) is on the floor, at distance \( d_2 = 6.00 \text{ mm} \) horizontally from particle 1. What is the \( x \) component of the electrostatic force on particle 2 due to particle 1?

**40** In Fig. 21-23, particles 1 and 2 are fixed in place, but particle 3 is free to move. If the net electrostatic force on particle 3 due to particles 1 and 2 is zero and \( L_{23} = 2.00L_{12} \), what is the ratio \( q_1/q_2 \)?

**41** (a) What equal positive charges would have to be placed on Earth and on the Moon to neutralize their gravitational attraction? (b) Why don’t you need to know the lunar distance to solve this problem? (c) How many kilograms of hydrogen ions (that is, protons) would be needed to provide the positive charge calculated in (a)?
42 In Fig. 21-39, two tiny conducting balls of identical mass $m$ and identical charge $q$ hang from nonconducting threads of length $L$. Assume that $\theta$ is so small that $\tan \theta$ can be replaced by its approximate equal, $\sin \theta$.(a) Show that

$$x = \left( \frac{q^2 L}{2 \pi \varepsilon_0 mg} \right)^{1/3}$$

gives the equilibrium separation $x$ of the balls. (b) If $L = 120$ cm, $m = 10$ g, and $x = 5.0$ cm, what is $|q|$?

43 (a) Explain what happens to the balls of Problem 42 if one of them is discharged (loses its charge $q$ to, say, the ground). (b) Find the new equilibrium separation $x$, using the given values of $L$ and $m$ and the computed value of $|q|$.

44 SSM How far apart must two protons be if the magnitude of the electrostatic force acting on either one due to the other is equal to the magnitude of the gravitational force on a proton at Earth’s surface?

45 How many megacoulombs of positive charge are in 1.00 mol of neutral molecular-hydrogen gas (H$_2$)?

46 In Fig. 21-40, four particles are fixed along an $x$ axis, separated by distances $d = 2.00$ cm. The charges are $q_1 = +2e$, $q_2 = -e$, $q_3 = +e$, and $q_4 = +4e$, with $e = 1.60 \times 10^{-19}$ C. In unit-vector notation, what is the net electrostatic force on (a) particle 1 and (b) particle 2 due to the other particles?

47 CC Point charges of +6.0 $\mu$C and −4.0 $\mu$C are placed on an $x$ axis, at $x = 8.0$ m and $x = 16$ m, respectively. What charge must be placed at $x = 24$ m so that any charge placed at the origin would experience no electrostatic force?

48 In Fig. 21-41, three identical conducting spheres form an equilateral triangle of side length $d = 20.0$ cm. The sphere radii are much smaller than $d$, and the sphere charges are $q_A = -2.00$ nC, $q_B = -4.00$ nC, and $q_C = +8.00$ nC. (a) What is the magnitude of the electrostatic force between spheres $A$ and $C$? The following steps are then taken: $A$ and $B$ are connected by a thin wire and then disconnected; $B$ is grounded by the wire, and the wire is then removed; $B$ and $C$ are connected by the wire and then disconnected. What are now the magnitudes of the electrostatic force (b) between spheres $A$ and $C$ and (c) between spheres $B$ and $C$?

49 A neutron consists of one “up” quark of charge $+2e/3$ and two “down” quarks each having charge $-e/3$. If we assume that the down quarks are $2.6 \times 10^{-13}$ m apart inside the neutron, what is the magnitude of the electrostatic force between them?

50 Figure 21-42 shows a long, nonconducting, massless rod of length $L$, pivoted at its center and balanced with a block of weight $W$ at a distance $x$ from the left end. At the left and right ends of the rod are attached small conducting spheres with positive charges $q$ and $2q$, respectively. A distance $h$ directly beneath each of these spheres is a fixed sphere with positive charge $Q$. (a) Find the distance $x$ when the rod is horizontal and balanced. (b) What value should $h$ have so that the rod exerts no vertical force on the bearing when the rod is horizontal and balanced?

51 A charged nonconducting rod, with a length of 2.00 m and a cross-sectional area of 4.00 cm$^2$, lies along the positive side of an $x$ axis with one end at the origin. The volume charge density $\rho$ is charge per unit volume in coulombs per cubic meter. How many excess electrons are on the rod if $\rho$ is (a) uniform, with a value of $-4.00 \mu$C/m$^3$, and (b) nonuniform, with a value given by $\rho = bx^2$, where $b = -2.00 \mu$C/m$^2$?

52 A particle of charge $Q$ is fixed at the origin of an $xy$ coordinate system. At $t = 0$ a particle ($m = 0.800$ g, $q = 4.00 \mu$C) is located on the $x$ axis at $x = 20.0$ cm, moving with a speed of 50.0 m/s in the positive $y$ direction. For what value of $Q$ will the moving particle execute circular motion? (Neglect the gravitational force on the particle.)

53 What would be the magnitude of the electrostatic force between two 1.00 C point charges separated by a distance of (a) 1.00 m and (b) 1.00 km if such point charges existed (they do not) and this configuration could be set up?

54 A charge of 6.0 $\mu$C is to be split into two parts that are then separated by 3.0 mm. What is the maximum possible magnitude of the electrostatic force between those two parts?

55 Of the charge $Q$ on a tiny sphere, a fraction $\alpha$ is to be transferred to a second, nearby sphere. The spheres can be treated as particles. (a) What value of $\alpha$ maximizes the magnitude $F$ of the electrostatic force between the two spheres? What are the (b) smaller and (c) larger values of $\alpha$ that put $F$ at half the maximum magnitude?

56 If a cat repeatedly rubs against your cotton slacks on a dry day, the charge transfer between the cat hair and the cotton can leave you with an excess charge of $-2.00 \mu$C. (a) How many electrons are transferred between you and the cat? You will gradually discharge via the floor, but if instead of waiting, you immediately reach toward a faucet, a painful spark can suddenly appear as your fingers near the faucet. (b) In that spark, do electrons flow from you to the faucet or vice versa? (c) Just before the spark appears, do you induce positive or negative charge on the faucet? (d) If, instead, the cat reaches a paw toward the faucet, which way do electrons flow in the resulting spark? (e) If you stroke a cat with a bare hand on a dry day, you should take care not to bring your fingers near the cat’s nose or you will hurt it with a spark. Considering that cat hair is an insulator, explain how the spark can appear.

57 We know that the negative charge on the electron and the positive charge on the proton are equal. Suppose, however, that these magnitudes differ from each other by 0.00010%. With what force would two copper coins, placed 1.0 m apart, repel each other? Assume that each coin contains $3 \times 10^{22}$ copper atoms. (Hint: A neutral copper atom contains 29 protons and 29 electrons.) What do you conclude?
58 In Fig. 21-26, particle 1 of charge $-80.0 \ \mu\text{C}$ and particle 2 of charge $+40.0 \ \mu\text{C}$ are held at separation $L = 20.0 \ \text{cm}$ on an $x$ axis. In unit-vector notation, what is the net electrostatic force on particle 3, of charge $q_3 = 20.0 \ \mu\text{C}$, if particle 3 is placed at (a) $x = 40.0 \ \text{cm}$ and (b) $x = 80.0 \ \text{cm}$? What should be the (c) $x$ and (d) $y$ coordinates of particle 3 if the net electrostatic force on it due to particles 1 and 2 is zero?

59 What is the total charge in coulombs of 75.0 kg of electrons?

60 In Fig. 21-43, six charged particles surround particle 7 at radial distances of either $d = 1.0 \ \text{cm}$ or $2d$, as drawn. The charges are $q_1 = +2e, q_2 = +4e, q_3 = +e, q_4 = +4e, q_5 = +2e, q_6 = +8e, q_7 = +6e$, with $e = 1.60 \times 10^{-19} \ \text{C}$. What is the magnitude of the net electrostatic force on particle 7?

61 Three charged particles form a triangle: particle 1 with charge $Q_1 = 80.0 \ \text{nC}$ is at $xy$ coordinates $(0, 3.00 \ \text{mm})$, particle 2 with charge $Q_2$ is at $(0, -3.00 \ \text{mm})$, and particle 3 with charge $q = 18.0 \ \text{nC}$ is at $(4.00 \ \text{mm}, 0)$. In unit-vector notation, what is the electrostatic force on particle 3 due to the other two particles if $Q_2$ is equal to (a) $80.0 \ \text{nC}$ and (b) $-80.0 \ \text{nC}$?

62 In Fig. 21-44, what are the (a) magnitude and (b) direction of the net electrostatic force on particle 4 due to the other three particles? All four particles are fixed in the $xy$ plane, and $q_1 = -3.20 \times 10^{-19} \ \text{C}, q_2 = +3.20 \times 10^{-19} \ \text{C}, q_3 = +6.40 \times 10^{-19} \ \text{C}, q_4 = +3.20 \times 10^{-19} \ \text{C}, \theta_1 = 35.0^\circ, d_1 = 3.00 \ \text{cm}$, and $d_2 = d_3 = 2.00 \ \text{cm}$.

63 Two point charges of 30 nC and $-40 \ \text{nC}$ are held fixed on an $x$ axis, at the origin and at $x = 72 \ \text{cm}$, respectively. A particle with a charge of 42 $\mu\text{C}$ is released from rest at $x = 28 \ \text{cm}$. If the initial acceleration of the particle has a magnitude of 100 km/s$^2$, what is the particle's mass?

64 Two small, positively charged spheres have a combined charge of $5.0 \times 10^{-5} \ \text{C}$. If each sphere is repelled from the other by an electrostatic force of 1.0 N when the spheres are 2.0 m apart, what is the charge on the sphere with the smaller charge?

65 The initial charges on the three identical metal spheres in Fig. 21-24 are the following: sphere $A$, $Q$; sphere $B$, $-Q/4$; and sphere $C$, $Q/2$, where $Q = 2.00 \times 10^{-14} \ \text{C}$. Spheres $A$ and $B$ are fixed in place, with a center-to-center separation of $d = 1.20 \ \text{m}$, which is much larger than the spheres. Sphere $C$ is touched first to sphere $A$ and then to sphere $B$ and is then removed. What then is the magnitude of the electrostatic force between spheres $A$ and $B$?

66 An electron is in a vacuum near Earth’s surface and located at $y = 0$ on a vertical $y$ axis. At what value of $y$ should a second electron be placed such that its electrostatic force on the first electron balances the gravitational force on the first electron?

67 In Fig. 21-26, particle 1 of charge $-5.00q$ and particle 2 of charge $+2.00q$ are held at separation $L$ on an $x$ axis. If particle 3 of unknown charge $q_3$ is to be located such that the net electrostatic force on it from particles 1 and 2 is zero, what must be the (a) $x$ and (b) $y$ coordinates of particle 3?

68 Two engineering students, John with a mass of 90 kg and Mary with a mass of 45 kg, are 30 m apart. Suppose each has a 0.01% imbalance in the amount of positive and negative charge, one student being positive and the other negative. Find the order of magnitude of the electrostatic force of attraction between them by replacing each student with a sphere of water having the same mass as the student.

69 In the radioactive decay of Eq. 21-13, a $^{238}$U nucleus transforms to $^{234}$Th and an ejected $^4$He. (These are nuclei, not atoms, and thus electrons are not involved.) When the separation between $^{238}$Th and $^4$He is $9.0 \times 10^{-15} \ \text{m}$, what are the magnitudes of (a) the electrostatic force between them and (b) the acceleration of the $^4$He particle?

70 In Fig. 21-25, four particles form a square. The charges are $q_1 = +Q, q_2 = q_3 = q$, and $q_4 = -2.00Q$. What is $q/Q$ if the net electrostatic force on particle 1 is zero?

71 In a spherical metal shell of radius $R$, an electron is shot from the center directly toward a tiny hole in the shell, through which it escapes. The shell is negatively charged with a surface charge density (charge per unit area) of $6.90 \times 10^{-13} \ \text{C/m}^2$. What is the magnitude of the electron’s acceleration when it reaches radial distances (a) $r = 0.500R$ and (b) $2.00R$?

72 An electron is projected with an initial speed $v_i = 3.2 \times 10^6 \ \text{m/s}$ directly toward a very distant proton that is at rest. Because the proton mass is large relative to the electron mass, assume that the proton remains at rest. By calculating the work done on the electron by the electrostatic force, determine the distance between the two particles when the electron instantaneously has speed $2v_i$.

73 In an early model of the hydrogen atom (the Bohr model), the electron orbits the proton in uniformly circular motion. The radius of the circle is restricted (quantized) to certain values given by

$$ r = n^2a_0, \quad \text{for } n = 1, 2, 3, \ldots, $$

where $a_0 = 52.92 \ \text{pm}$. What is the speed of the electron if it orbits in (a) the smallest allowed orbit and (b) the second smallest orbit? (c) If the electron moves to larger orbits, does its speed increase, decrease, or stay the same?

74 A 100 W lamp has a steady current of 0.83 A in its filament. How long is required for 1 mol of electrons to pass through the lamp?

75 The charges of an electron and a positron are $-e$ and $+e$. The mass of each is $9.11 \times 10^{-31} \ \text{kg}$. What is the ratio of the electrical force to the gravitational force between an electron and a positron?
CHAPTER 22

Electric Fields

22-1 THE ELECTRIC FIELD

Learning Objectives

After reading this module, you should be able to . . .

22.01 Identify that at every point in the space surrounding a charged particle, the particle sets up an electric field \( \vec{E} \), which is a vector quantity and thus has both magnitude and direction.

22.02 Identify how an electric field \( \vec{E} \) can be used to explain how a charged particle can exert an electrostatic force \( \vec{F} \) on a second charged particle even though there is no contact between the particles.

22.03 Explain how a small positive test charge is used (in principle) to measure the electric field at any given point.

22.04 Explain electric field lines, including where they originate and terminate and what their spacing represents.

Key Ideas

- A charged particle sets up an electric field (a vector quantity) in the surrounding space. If a second charged particle is located in that space, an electrostatic force acts on it due to the magnitude and direction of the field at its location.
- The electric field \( \vec{E} \) at any point is defined in terms of the electrostatic force \( \vec{F} \) that would be exerted on a positive test charge \( q_0 \) placed there:
  \[
  \vec{E} = \frac{\vec{F}}{q_0}.
  \]
- Electric field lines help us visualize the direction and magnitude of electric fields. The electric field vector at any point is tangent to the field line through that point. The density of field lines in that region is proportional to the magnitude of the electric field there. Thus, closer field lines represent a stronger field.
- Electric field lines originate on positive charges and terminate on negative charges. So, a field line extending from a positive charge must end on a negative charge.

What Is Physics?

Figure 22-1 shows two positively charged particles. From the preceding chapter we know that an electrostatic force acts on particle 1 due to the presence of particle 2. We also know the force direction and, given some data, we can calculate the force magnitude. However, here is a leftover nagging question. How does particle 1 “know” of the presence of particle 2? That is, since the particles do not touch, how can particle 2 push on particle 1—how can there be such an action at a distance?

One purpose of physics is to record observations about our world, such as the magnitude and direction of the push on particle 1. Another purpose is to provide an explanation of what is recorded. Our purpose in this chapter is to provide such an explanation to this nagging question about electric force at a distance.

The explanation that we shall examine here is this: Particle 2 sets up an electric field at all points in the surrounding space, even if the space is a vacuum. If we place particle 1 at any point in that space, particle 1 knows of the presence of particle 2 because it is affected by the electric field particle 2 has already set up at that point. Thus, particle 2 pushes on particle 1 not by touching it as you would push on a coffee mug by making contact. Instead, particle 2 pushes by means of the electric field it has set up.

Figure 22-1 How does charged particle 2 push on charged particle 1 when they have no contact?
Our goals in this chapter are to (1) define electric field, (2) discuss how to calculate it for various arrangements of charged particles and objects, and (3) discuss how an electric field can affect a charged particle (as in making it move).

The Electric Field

A lot of different fields are used in science and engineering. For example, a temperature field for an auditorium is the distribution of temperatures we would find by measuring the temperature at many points within the auditorium. Similarly, we could define a pressure field in a swimming pool. Such fields are examples of scalar fields because temperature and pressure are scalar quantities, having only magnitudes and not directions.

In contrast, an electric field is a vector field because it is responsible for conveying the information for a force, which involves both magnitude and direction. This field consists of a distribution of electric field vectors \( \mathbf{E} \), one for each point in the space around a charged object. In principle, we can define \( \mathbf{E} \) at some point near the charged object, such as point \( P \) in Fig. 22-2a, with this procedure: At \( P \), we place a particle with a small positive charge \( q_0 \), called a test charge because we use it to test the field. (We want the charge to be small so that it does not disturb the object’s charge distribution.) We then measure the electrostatic force \( \mathbf{F} \) that acts on the test charge. The electric field at that point is then

\[
\mathbf{E} = \frac{\mathbf{F}}{q_0} \quad \text{(electric field).} \tag{22-1}
\]

Because the test charge is positive, the two vectors in Eq. 22-1 are in the same direction, so the direction of \( \mathbf{E} \) is the direction we measure for \( \mathbf{F} \). The magnitude of \( \mathbf{E} \) at point \( P \) is \( F/q_0 \). As shown in Fig. 22-2b, we always represent an electric field with an arrow with its tail anchored on the point where the measurement is made. (This may sound trivial, but drawing the vectors any other way usually results in errors. Also, another common error is to mix up the terms force and field because they both start with the letter f. Electric force is a push or pull. Electric field is an abstract property set up by a charged object.) From Eq. 22-1, we see that the SI unit for the electric field is the newton per coulomb (N/C).

We can shift the test charge around to various other points, to measure the electric fields there, so that we can figure out the distribution of the electric field set up by the charged object. That field exists independent of the test charge. It is something that a charged object sets up in the surrounding space (even vacuum), independent of whether we happen to come along to measure it.

For the next several modules, we determine the field around charged particles and various charged objects. First, however, let’s examine a way of visualizing electric fields.

Electric Field Lines

Look at the space in the room around you. Can you visualize a field of vectors throughout that space—vectors with different magnitudes and directions? As impossible as that seems, Michael Faraday, who introduced the idea of electric fields in the 19th century, found a way. He envisioned lines, now called electric field lines, in the space around any given charged particle or object.

Figure 22-3 gives an example in which a sphere is uniformly covered with negative charge. If we place a positive test charge at any point near the sphere (Fig. 22-3a), we find that an electrostatic force pulls on it toward the center of the sphere. Thus at every point around the sphere, an electric field vector points radially inward toward the sphere. We can represent this electric field with
In Fig. 22-3b, the electric field lines as in Fig. 22-3b. At any point, such as the one shown, the direction of the field line through the point matches the direction of the electric vector at that point.

The rules for drawing electric field lines are these: (1) At any point, the electric field vector must be tangent to the electric field line through that point and in the same direction. (This is easy to see in Fig. 22-3 where the lines are straight, but we’ll see some curved lines soon.) (2) In a plane perpendicular to the field lines, the relative density of the lines represents the relative magnitude of the field there, with greater density for greater magnitude.

If the sphere in Fig. 22-3 were uniformly covered with positive charge, the electric field vectors at all points around it would be radially outward and thus so would the electric field lines. So, we have the following rule:

Electric field lines extend away from positive charge (where they originate) and toward negative charge (where they terminate).

In Fig. 22-3b, they originate on distant positive charges that are not shown.

For another example, Fig. 22-4a shows part of an infinitely large, nonconducting sheet (or plane) with a uniform distribution of positive charge on one side. If we place a positive test charge at any point near the sheet (on either side), we find that the electrostatic force on the particle is outward and perpendicular to the sheet. The perpendicular orientation is reasonable because any force component that is, say, upward is balanced out by an equal component that is downward. That leaves only outward, and thus the electric field vectors and the electric field lines must also be outward and perpendicular to the sheet, as shown in Figs. 22-4b and c.

Because the charge on the sheet is uniform, the field vectors and the field lines are also. Such a field is a uniform electric field, meaning that the electric field has the same magnitude and direction at every point within the field. (This is a lot easier to work with than a nonuniform field, where there is variation from point to point.) Of course, there is no such thing as an infinitely large sheet. That is just a way of saying that we are measuring the field at points close to the sheet relative to the size of the sheet and that we are not near an edge.

Figure 22-5 shows the field lines for two particles with equal positive charges. Now the field lines are curved, but the rules still hold: (1) the electric field vector at any given point must be tangent to the field line at that point and in the same direction, as shown for one vector, and (2) a closer spacing means a larger field magnitude. To imagine the full three-dimensional pattern of field lines around the particles, mentally rotate the pattern in Fig. 22-5 around the axis of symmetry, which is a vertical line through both particles.
22-2 THE ELECTRIC FIELD DUE TO A CHARGED PARTICLE

Learning Objectives

After reading this module, you should be able to . . .

22.05 In a sketch, draw a charged particle, indicate its sign, pick a nearby point, and then draw the electric field vector \( \vec{E} \) at that point, with its tail anchored on the point.

22.06 For a given point in the electric field of a charged particle, identify the direction of the field vector \( \vec{E} \) when the particle is positively charged and when it is negatively charged.

22.07 For a given point in the electric field of a charged particle, apply the relationship between the field magnitude \( E \), the charge magnitude \( |q| \), and the distance \( r \) between the point and the particle.

22.08 Identify that the equation given here for the magnitude of an electric field applies only to a particle, not an extended object.

22.09 If more than one electric field is set up at a point, draw each electric field vector and then find the net electric field by adding the individual electric fields as vectors (not as scalars).

Key Ideas

- The magnitude of the electric field \( \vec{E} \) set up by a particle with charge \( q \) at distance \( r \) from the particle is
  \[ E = \frac{1}{4\pi\varepsilon_0} \frac{|q|}{r^2}. \]

- The electric field vectors set up by a positively charged particle all point directly away from the particle. Those set up by a negatively charged particle all point directly toward the particle.

- If more than one charged particle sets up an electric field at a point, the net electric field is the vector sum of the individual electric fields—electric fields obey the superposition principle.

The Electric Field Due to a Point Charge

To find the electric field due to a charged particle (often called a point charge), we place a positive test charge at any point near the particle, at distance \( r \). From Coulomb’s law (Eq. 21-4), the force on the test charge due to the particle with charge \( q \) is

\[ \vec{F} = \frac{1}{4\pi\varepsilon_0} \frac{qq_0}{r^2} \hat{r}. \]

As previously, the direction of \( \vec{F} \) is directly away from the particle if \( q \) is positive (because \( q_0 \) is positive) and directly toward it if \( q \) is negative. From Eq. 22-1, we can now write the electric field set up by the particle (at the location of the test charge) as

\[ \vec{E} = \frac{\vec{F}}{q_0} = \frac{1}{4\pi\varepsilon_0} \frac{q}{r^2} \hat{r} \quad \text{(charged particle)}. \quad (22-2) \]

Let’s think through the directions again. The direction of \( \vec{E} \) matches that of the force on the positive test charge: directly away from the point charge if \( q \) is positive and directly toward it if \( q \) is negative.

So, if given another charged particle, we can immediately determine the directions of the electric field vectors near it by just looking at the sign of the charge \( q \). We can find the magnitude at any given distance \( r \) by converting Eq. 22-2 to a magnitude form:

\[ E = \frac{1}{4\pi\varepsilon_0} \frac{|q|}{r^2} \quad \text{(charged particle)}. \quad (22-3) \]

We write \( |q| \) to avoid the danger of getting a negative \( E \) when \( q \) is negative, and then thinking the negative sign has something to do with direction. Equation 22-3 gives magnitude \( E \) only. We must think about the direction separately.

Figure 22-6 gives a number of electric field vectors at points around a positively charged particle, but be careful. Each vector represents the vector
quantity at the point where the tail of the arrow is anchored. The vector is not something that stretches from a “here” to a “there” as with a displacement vector.

In general, if several electric fields are set up at a given point by several charged particles, we can find the net field by placing a positive test particle at the point and then writing out the force acting on it due to each particle, such as \( \vec{F}_0 \) due to particle 1. Forces obey the principle of superposition, so we just add the forces as vectors:

\[
\vec{F}_0 = \vec{F}_{01} + \vec{F}_{02} + \cdots + \vec{F}_{0n},
\]

To change over to electric field, we repeatedly use Eq. 22-1 for each of the individual forces:

\[
\vec{E} = \frac{\vec{F}}{q_0} = \frac{\vec{F}_{01}}{q_0} + \frac{\vec{F}_{02}}{q_0} + \cdots + \frac{\vec{F}_{0n}}{q_0}
= \vec{E}_1 + \vec{E}_2 + \cdots + \vec{E}_n.
\]  \hspace{1cm} (22-4)

This tells us that electric fields also obey the principle of superposition. If you want the net electric field at a given point due to several particles, find the electric field due to each particle (such as \( \vec{E}_1 \) due to particle 1) and then sum the fields as vectors. (As with electrostatic forces, you cannot just willy-nilly add up the magnitudes.) This addition of fields is the subject of many of the homework problems.

**Checkpoint 1**

The figure here shows a proton p and an electron e on an x axis. What is the direction of the electric field due to the electron at (a) point S and (b) point R? What is the direction of the net electric field at (c) point R and (d) point S?

**Sample Problem 22.01   Net electric field due to three charged particles**

Figure 22-7a shows three particles with charges \( q_1 = +2Q \), \( q_2 = -2Q \), and \( q_3 = -4Q \), each a distance \( d \) from the origin. What net electric field \( \vec{E} \) is produced at the origin?

**KEY IDEA**

Charges \( q_1, q_2, \) and \( q_3 \) produce electric field vectors \( \vec{E}_1, \vec{E}_2, \) and \( \vec{E}_3, \) respectively, at the origin, and the net electric field is the vector sum \( \vec{E} = \vec{E}_1 + \vec{E}_2 + \vec{E}_3. \) To find this sum, we first must find the magnitudes and orientations of the three field vectors.

**Magnitudes and directions:** To find the magnitude of \( \vec{E}_1 \), which is due to \( q_1 \), we use Eq. 22-3, substituting \( d \) for \( r \) and \( 2Q \) for \( q \) and obtaining

\[
E_1 = \frac{1}{4\pi\varepsilon_0} \frac{2Q}{d^2}.
\]

Similarly, we find the magnitudes of \( \vec{E}_2 \) and \( \vec{E}_3 \) to be

\[
E_2 = \frac{1}{4\pi\varepsilon_0} \frac{2Q}{d^2} \quad \text{and} \quad E_3 = \frac{1}{4\pi\varepsilon_0} \frac{4Q}{d^2}.
\]

**Figure 22-7** (a) Three particles with charges \( q_1, q_2, \) and \( q_3 \) are at the same distance \( d \) from the origin. (b) The electric field vectors \( \vec{E}_1, \vec{E}_2, \) and \( \vec{E}_3, \) at the origin due to the three particles. (c) The electric field vector \( \vec{E}_3 \) and the vector sum \( \vec{E}_1 + \vec{E}_2 \) at the origin.
We next must find the orientations of the three electric field vectors at the origin. Because \( q_1 \) is a positive charge, the electric field vector it produces points directly away from it, and because \( q_2 \) and \( q_3 \) are both negative, the field vectors they produce point directly toward each of them. Thus, the three electric field vectors produced at the origin by the three charged particles are oriented as in Fig. 22-7b. (Caution: Note that we have placed the tails of the vectors at the point where the fields are to be evaluated; doing so decreases the chance of error. Error becomes very probable if the tails of the field vectors are placed on the particles creating the fields.)

**Adding the fields:** We can now add the fields vectorially just as we added force vectors in Chapter 21. However, here we can use symmetry to simplify the procedure. From Fig. 22-7b, we see that electric fields \( \vec{E}_1 \) and \( \vec{E}_2 \) have the same direction. Hence, their vector sum has that direction and has the magnitude

\[
E_1 + E_2 = \frac{1}{4\pi\varepsilon_0} \frac{2Q}{d^2} + \frac{1}{4\pi\varepsilon_0} \frac{2Q}{d^2} = \frac{1}{4\pi\varepsilon_0} \frac{4Q}{d^2},
\]

which happens to equal the magnitude of field \( \vec{E}_3 \).

We must now combine two vectors, \( \vec{E}_3 \) and the vector sum \( \vec{E}_1 + \vec{E}_2 \), that have the same magnitude and that are oriented symmetrically about the x axis, as shown in Fig. 22-7c. From the symmetry of Fig. 22-7c, we realize that the equal \( y \) components of our two vectors cancel (one is upward and the other is downward) and the equal \( x \) components add (both are rightward). Thus, the net electric field \( \vec{E} \) at the origin is in the positive direction of the \( x \) axis and has the magnitude

\[
E = 2E_x = 2E_3 \cos 30^\circ = (2) \frac{1}{4\pi\varepsilon_0} \frac{4Q}{d^2} (0.866) = \frac{6.93Q}{4\pi\varepsilon_0 d^2}. \quad \text{(Answer)}
\]

---

**22-3 THE ELECTRIC FIELD DUE TO A DIPOLE**

**Learning Objectives**

*After reading this module, you should be able to . . .*

- **22.10** Draw an electric dipole, identifying the charges (sizes and signs), dipole axis, and direction of the electric dipole moment.
- **22.11** Identify the direction of the electric field at any given point along the dipole axis, including between the charges.
- **22.12** Outline how the equation for the electric field due to an electric dipole is derived from the equations for the electric field due to the individual charged particles that form the dipole.
- **22.13** For a single charged particle and an electric dipole, compare the rate at which the electric field magnitude decreases with increase in distance. That is, identify which drops off faster.
- **22.14** For an electric dipole, apply the relationship between the magnitude \( p \) of the dipole moment, the separation \( d \) between the charges, and the magnitude \( q \) of either of the charges.
- **22.15** For any distant point along a dipole axis, apply the relationship between the electric field magnitude \( E \), the distance \( z \) from the center of the dipole, and either the dipole moment magnitude \( p \) or the product of charge magnitude \( q \) and charge separation \( d \).

**Key Ideas**

- An electric dipole consists of two particles with charges of equal magnitude \( q \) but opposite signs, separated by a small distance \( d \).
- The electric dipole moment \( p \) has magnitude \( qd \) and points from the negative charge to the positive charge.
- The magnitude of the electric field set up by an electric dipole at a distant point on the dipole axis (which runs through both particles) can be written in terms of either the product \( qd \) or the magnitude \( p \) of the dipole moment:

\[
E = \frac{1}{2\pi\varepsilon_0} \frac{qd}{z^3} = \frac{1}{2\pi\varepsilon_0} \frac{p}{z^3},
\]

where \( z \) is the distance between the point and the center of the dipole.

- Because of the \( 1/z^3 \) dependence, the field magnitude of an electric dipole decreases more rapidly with distance than the field magnitude of either of the individual charges forming the dipole, which depends on \( 1/r^2 \).
The Electric Field Due to an Electric Dipole

Figure 22-8 shows the pattern of electric field lines for two particles that have the same charge magnitude \( q \) but opposite signs, a very common and important arrangement known as an electric dipole. The particles are separated by distance \( d \) and lie along the dipole axis, an axis of symmetry around which you can imagine rotating the pattern in Fig. 22-8. Let’s label that axis as a \( z \) axis. Here we restrict our interest to the magnitude and direction of the electric field \( \mathbf{E} \) at an arbitrary point \( P \) along the dipole axis, at distance \( z \) from the dipole’s midpoint.

Figure 22-9a shows the electric fields set up at \( P \) by each particle. The nearer particle with charge \( +q \) sets up field \( E_{(+)} \) in the positive direction of the \( z \) axis (directly away from the particle). The farther particle with charge \( -q \) sets up a smaller field \( E_{(-)} \) in the negative direction (directly toward the particle). We want the net field at \( P \), as given by Eq. 22-4. However, because the field vectors are along the same axis, let’s simply indicate the vector directions with plus and minus signs, as we commonly do with forces along a single axis. Then we can write the magnitude of the net field at \( P \) as

\[
E = E_{(+)} - E_{(-)}
\]

After a little algebra, we can rewrite this equation as

\[
E = \frac{q}{4\pi\varepsilon_0 z^2} \left( \frac{1}{\left(1 - \frac{d}{2z}\right)^2} - \frac{1}{\left(1 + \frac{d}{2z}\right)^2} \right).
\]  

(22-6)

After forming a common denominator and multiplying its terms, we come to

\[
E = \frac{q}{4\pi\varepsilon_0 z^2} \frac{2dz}{\left(1 - \left(\frac{d}{2z}\right)^2\right)^2} = \frac{q}{2\pi\varepsilon_0 z^3} \frac{d}{\left(1 - \left(\frac{d}{2z}\right)^2\right)^2}.
\]  

(22-7)

We are usually interested in the electrical effect of a dipole only at distances that are large compared with the dimensions of the dipole—that is, at distances such that \( z \gg d \). At such large distances, we have \( d/2z \ll 1 \) in Eq. 22-7. Thus, in our approximation, we can neglect the \( d/2z \) term in the denominator, which leaves us with

\[
E = \frac{1}{2\pi\varepsilon_0} \frac{qd}{z^3}.
\]  

(22-8)

The product \( qd \), which involves the two intrinsic properties \( q \) and \( d \) of the dipole, is the magnitude \( p \) of a vector quantity known as the electric dipole moment \( \mathbf{p} \) of the dipole. (The unit of \( \mathbf{p} \) is the coulomb-meter.) Thus, we can write Eq. 22-8 as

\[
E = \frac{1}{2\pi\varepsilon_0} \frac{p}{z^3} \quad \text{(electric dipole)}.
\]  

(22-9)

The direction of \( \mathbf{p} \) is taken to be from the negative to the positive end of the dipole, as indicated in Fig. 22-9b. We can use the direction of \( \mathbf{p} \) to specify the orientation of a dipole.

Equation 22-9 shows that, if we measure the electric field of a dipole only at distant points, we can never find \( q \) and \( d \) separately; instead, we can find only their product. The field at distant points would be unchanged if, for example, \( q \)
were doubled and \(d\) simultaneously halved. Although Eq. 22-9 holds only for distant points along the dipole axis, it turns out that \(E\) for a dipole varies as \(1/r^3\) for all distant points, regardless of whether they lie on the dipole axis; here \(r\) is the distance between the point in question and the dipole center.

Inspection of Fig. 22-9 and of the field lines in Fig. 22-8 shows that the direction of \(E\) for distant points on the dipole axis is always the direction of the dipole moment vector \(\vec{p}\). This is true whether point \(P\) in Fig. 22-9a is on the upper or the lower part of the dipole axis.

Inspection of Eq. 22-9 shows that if you double the distance of a point from a dipole, the electric field at the point drops by a factor of 8. If you double the distance from a single point charge, however (see Eq. 22-3), the electric field drops only by a factor of 4. Thus the electric field of a dipole decreases more rapidly with distance than does the electric field of a single charge. The physical reason for this rapid decrease in electric field for a dipole is that from distant points a dipole looks like two particles that almost—but not quite—coincide. Thus, because they have charges of equal magnitude but opposite signs, their electric fields at distant points almost—but not quite—cancel each other.

**Sample Problem 22.02  Electric dipole and atmospheric sprites**

Sprites (Fig. 22-10a) are huge flashes that occur far above a large thunderstorm. They were seen for decades by pilots flying at night, but they were so brief and dim that most pilots figured they were just illusions. Then in the 1990s sprites were captured on video. They are still not well understood but are believed to be produced when especially powerful lightning occurs between the ground and storm clouds, particularly when the lightning transfers a huge amount of negative charge \(-q\) from the ground to the base of the clouds (Fig. 22-10b).

Just after such a transfer, the ground has a complicated distribution of positive charge. However, we can model the electric field due to the charges in the clouds and the ground by assuming a vertical electric dipole that has charge \(-q\) at cloud height \(h\) and charge \(+q\) at below-ground depth \(h\) (Fig. 22-10c). If \(q = 200\ \text{C}\) and \(h = 6.0\ \text{km}\), what is the magnitude of the dipole’s electric field at altitude \(z_1 = 30\ \text{km}\) somewhat above the clouds and altitude \(z_2 = 60\ \text{km}\) somewhat above the stratosphere?

**KEY IDEA**

We can approximate the magnitude \(E\) of an electric dipole’s electric field on the dipole axis with Eq. 22-8.

**Calculations:** We write that equation as

\[
E = \frac{1}{2\pi\varepsilon_0} \frac{q(2h)}{z^3},
\]

where \(2h\) is the separation between \(-q\) and \(+q\) in Fig. 22-10c. For the electric field at altitude \(z_1 = 30\ \text{km}\), we find

\[
E = \frac{1}{2\pi\varepsilon_0} \frac{(200\ \text{C})(2)(6.0 \times 10^3\ \text{m})}{(30 \times 10^3\ \text{m})^3} = 1.6 \times 10^3\ \text{N/C}
\]

(Answer)

Similarly, for altitude \(z_2 = 60\ \text{km}\), we find

\[
E = 2.0 \times 10^2\ \text{N/C}
\]

(Answer)

As we discuss in Module 22-6, when the magnitude of...
an electric field exceeds a certain critical value \( E_c \), the field can pull electrons out of atoms (ionize the atoms), and then the freed electrons can run into other atoms, causing those atoms to emit light. The value of \( E_c \) depends on the density of the air in which the electric field exists. At altitude \( z_2 = 60 \text{ km} \) the density of the air is so low that \( E = 2.0 \times 10^2 \text{ N/C} \) exceeds \( E_c \), and thus light is emitted by the atoms in the air. That light forms sprites. Lower down, just above the clouds at \( z_1 = 30 \text{ km} \), the density of the air is much higher, \( E = 1.6 \times 10^3 \text{ N/C} \) does not exceed \( E_c \), and no light is emitted. Hence, sprites occur only far above storm clouds.

### Additional examples, video, and practice available at WileyPLUS

#### 22-4 The Electric Field Due to a Line of Charge

**Learning Objectives**

*After reading this module, you should be able to . . .*

22.16 For a uniform distribution of charge, find the linear charge density \( \lambda \) for charge along a line, the surface charge density \( \sigma \) for charge on a surface, and the volume charge density \( \rho \) for charge in a volume.

22.17 For charge that is distributed uniformly along a line, find the net electric field at a given point near the line by splitting the distribution up into charge elements \( dq \) and then summing (by integration) the electric field vectors \( d\vec{E} \) set up at the point by each element.

22.18 Explain how symmetry can be used to simplify the calculation of the electric field at a point near a line of uniformly distributed charge.

**Key Ideas**

- The equation for the electric field set up by a particle does not apply to an extended object with charge (said to have a continuous charge distribution).

- To find the electric field of an extended object at a point, we first consider the electric field set up by a charge element \( dq \) in the object, where the element is small enough for us to apply the equation for a particle. Then we sum, via integration, components of the electric fields \( d\vec{E} \) from all the charge elements.

- Because the individual electric fields \( d\vec{E} \) have different magnitudes and point in different directions, we first see if symmetry allows us to cancel out any of the components of the fields, to simplify the integration.

#### The Electric Field Due to a Line of Charge

So far we have dealt with only charged particles, a single particle or a simple collection of them. We now turn to a much more challenging situation in which a thin (approximately one-dimensional) object such as a rod or ring is charged with a huge number of particles, more than we could ever even count. In the next module, we consider two-dimensional objects, such as a disk with charge spread over a surface. In the next chapter we tackle three-dimensional objects, such as a sphere with charge spread through a volume.

*Heads Up.* Many students consider this module to be the most difficult in the book for a variety of reasons. There are lots of steps to take, a lot of vector features to keep track of, and after all that, we set up and then solve an integral. The worst part, however, is that the procedure can be different for different arrangements of the charge. Here, as we focus on a particular arrangement (a charged ring), be aware of the general approach, so that you can tackle other arrangements in the homework (such as rods and partial circles).

Figure 22-11 shows a thin ring of radius \( R \) with a uniform distribution of positive charge along its circumference. It is made of plastic, which means that the charge is fixed in place. The ring is surrounded by a pattern of electric field lines, but here we restrict our interest to an arbitrary point \( P \) on the central axis (the axis through the ring’s center and perpendicular to the plane of the ring), at distance \( z \) from the center point.

The charge of an extended object is often conveyed in terms of a charge density rather than the total charge. For a line of charge, we use the linear charge
density \( \lambda \) (the charge per unit length), with the SI unit of coulomb per meter. Table 22-1 shows the other charge densities that we shall be using for charged surfaces and volumes.

**First Big Problem.** So far, we have an equation for the electric field of a particle. (We can combine the field of several particles as we did for the electric dipole to generate a special equation, but we are still basically using Eq. 22-3). Now take a look at the ring in Fig. 22-11. That clearly is not a particle and so Eq. 22-3 does not apply. So what do we do?

The answer is to mentally divide the ring into differential elements of charge that are so small that we can treat them as though they are particles. Then we can apply Eq. 22-3.

**Second Big Problem.** We now know to apply Eq. 22-3 to each charge element \( dq \) (the front \( d \) emphasizes that the charge is very small) and can write an expression for its contribution of electric field \( d\vec{E} \) (the front \( d \) emphasizes that the contribution is very small). However, each such contributed field vector at \( P \) is in its own direction. How can we add them to get the net field at \( P \)?

The answer is to split the vectors into components and then separately sum one set of components and then the other set. However, first we check to see if one set simply all cancels out. (Canceling out components saves lots of work.)

**Third Big Problem.** There is a huge number of \( dq \) elements in the ring and thus a huge number of \( d\vec{E} \) components to add up, even if we can cancel out one set of components. How can we add up more components than we could even count? The answer is to add them by means of integration.

**Do It.** Let’s do all this (but again, be aware of the general procedure, not just the fine details). We arbitrarily pick the charge element shown in Fig. 22-11. Let \( ds \) be the arc length of that (or any other) \( dq \) element. Then in terms of the linear density \( \lambda \) (the charge per unit length), we have

\[
dq = \lambda \, ds. \tag{22-10}
\]

**An Element’s Field.** This charge element sets up the differential electric field \( d\vec{E} \) at \( P \), at distance \( r \) from the element, as shown in Fig. 22-11. (Yes, we are introducing a new symbol that is not given in the problem statement, but soon we shall replace it with “legal symbols.”) Next we rewrite the field equation for a particle (Eq. 22-3) in terms of our new symbols \( dE \) and \( dq \), but then we replace \( dq \) using Eq. 22-10. The field magnitude due to the charge element is

\[
dE = \frac{1}{4 \pi \varepsilon_0} \frac{dq}{r^2} = \frac{1}{4 \pi \varepsilon_0} \frac{\lambda \, ds}{r^2}. \tag{22-11}
\]

Notice that the illegal symbol \( r \) is the hypotenuse of the right triangle displayed in Fig. 22-11. Thus, we can replace \( r \) by rewriting Eq. 22-11 as

\[
dE = \frac{1}{4 \pi \varepsilon_0} \frac{\lambda \, ds}{(z^2 + R^2)}. \tag{22-12}
\]

Because every charge element has the same charge and the same distance from point \( P \), Eq. 22-12 gives the field magnitude contributed by each of them. Figure 22-11 also tells us that each contributed \( d\vec{E} \) leans at angle \( \theta \) to the central axis (the \( z \) axis) and thus has components perpendicular and parallel to that axis.

**Canceling Components.** Now comes the neat part, where we eliminate one set of those components. In Fig. 22-11, consider the charge element on the opposite side of the ring. It too contributes the field magnitude \( dE \) but the field vector leans at angle \( \theta \) in the opposite direction from the vector from our first charge element. Thus, to get the net field at \( P \), we can cancel these like Martian vectors.

---

</table>
element, as indicated in the side view of Fig. 22-12. Thus the two perpendicular components cancel. All around the ring, this cancelation occurs for every charge element and its symmetric partner on the opposite side of the ring. So we can neglect all the perpendicular components.

Adding Components. We have another big win here. All the remaining components are in the positive direction of the \( z \) axis, so we can just add them up as scalars. Thus we can already tell the direction of the net electric field at \( P \): directly away from the ring. From Fig. 22-12, we see that the parallel components each have magnitude \( dE \cos \theta \), but \( \theta \) is another illegal symbol. We can replace \( \cos \theta \) with legal symbols by again using the right triangle in Fig. 22-11 to write

\[
\cos \theta = \frac{z}{r} = \frac{z}{(z^2 + R^2)^{1/2}}. \tag{22-13}
\]

Multiplying Eq. 22-12 by Eq. 22-13 gives us the parallel field component from each charge element:

\[
dE \cos \theta = \frac{1}{4\pi \varepsilon_0} \frac{z\lambda}{(z^2 + R^2)^{3/2}} \, ds. \tag{22-14}
\]

Integrating. Because we must sum a huge number of these components, each small, we set up an integral that moves along the ring, from element to element, from a starting point (call it \( s = 0 \)) through the full circumference (\( s = 2\pi R \)). Only the quantity \( s \) varies as we go through the elements; the other symbols in Eq. 22-14 remain the same, so we move them outside the integral. We find

\[
E = \int dE \cos \theta = \frac{z\lambda}{4\pi \varepsilon_0(z^2 + R^2)^{3/2}} \int_0^{2\pi R} ds \\
= \frac{z\lambda(2\pi R)}{4\pi \varepsilon_0(z^2 + R^2)^{3/2}}. \tag{22-15}
\]

This is a fine answer, but we can also switch to the total charge by using \( \lambda = q/(2\pi R) \):

\[
E = \frac{qz}{4\pi \varepsilon_0(z^2 + R^2)^{3/2}} \tag{charged ring}. \tag{22-16}
\]

If the charge on the ring is negative, instead of positive as we have assumed, the magnitude of the field at \( P \) is still given by Eq. 22-16. However, the electric field vector then points toward the ring instead of away from it.

Let us check Eq. 22-16 for a point on the central axis that is so far away that \( z \gg R \). For such a point, the expression \( z^2 + R^2 \) in Eq. 22-16 can be approximated as \( z^2 \), and Eq. 22-16 becomes

\[
E = \frac{1}{4\pi \varepsilon_0} \frac{q}{z^2} \tag{charged ring at large distance}. \tag{22-17}
\]

This is a reasonable result because from a large distance, the ring “looks like” a point charge. If we replace \( z \) with \( r \) in Eq. 22-17, we indeed do have the magnitude of the electric field due to a point charge, as given by Eq. 22-3.

Let us next check Eq. 22-16 for a point at the center of the ring—that is, for \( z = 0 \). At that point, Eq. 22-16 tells us that \( E = 0 \). This is a reasonable result because if we were to place a test charge at the center of the ring, there would be no net electrostatic force acting on it; the force due to any element of the ring would be canceled by the force due to the element on the opposite side of the ring. By Eq. 22-1, if the force at the center of the ring were zero, the electric field there would also have to be zero.
Sample Problem 22.03 Electric field of a charged circular rod

Figure 22-13a shows a plastic rod with a uniform charge \(-Q\). It is bent in a 120° circular arc of radius \(r\) and symmetrically paced across an \(x\) axis with the origin at the center of curvature \(P\) of the rod. In terms of \(Q\) and \(r\), what is the electric field \(\vec{E}\) due to the rod at point \(P\)?

**KEY IDEA**

Because the rod has a continuous charge distribution, we must find an expression for the electric fields due to differential elements of the rod and then sum those fields via calculus.

**An element:** Consider a differential element having arc length \(ds\) and located at an angle \(\theta\) above the \(x\) axis (Figs. 22-13b and c). If we let \(\lambda\) represent the linear charge density of the rod, our element \(ds\) has a differential charge of magnitude \(dq = \lambda \, ds\).

**The element’s field:** Our element produces a differential electric field \(d\vec{E}\) at point \(P\), which is a distance \(r\) from the element. Treating the element as a point charge, we can rewrite Eq. 22-3 to express the magnitude of \(d\vec{E}\) as

\[
dE = \frac{1}{4\pi\varepsilon_0} \frac{dq}{r^2} = \frac{1}{4\pi\varepsilon_0} \frac{\lambda \, ds}{r^2}.
\]

The direction of \(d\vec{E}\) is toward \(ds\) because charge \(dq\) is negative.

**Symmetric partner:** Our element has a symmetrically located (mirror image) element \(ds’\) in the bottom half of the rod. The electric field \(d\vec{E}\) set up at \(P\) by \(ds’\) also has the magnitude given by Eq. 22-19, but the field vector points toward \(ds’\) as shown in Fig. 22-13d. If we resolve the electric field vectors of \(ds\) and \(ds’\) into \(x\) and \(y\) components as shown in Figs. 22-13e and f, we see that their \(y\) components cancel (because they have equal magnitudes and are in opposite directions). We also see that their \(x\) components have equal magnitudes and are in the same direction.

**Summing:** Thus, to find the electric field set up by the rod, we need sum (via integration) only the \(x\) components of the differential electric fields set up by all the differential elements of the rod. From Fig. 22-13f and Eq. 22-19, we can write

\[
dE_x = \frac{1}{4\pi\varepsilon_0} \frac{\lambda \, ds \cos \theta}{r^2}.
\]

These \(y\) components just cancel, so neglect them.

These \(x\) components add. Our job is to add all such components.

Here is the field the element creates.

Here is the field created by the symmetric element, same size and angle.

We use this to relate the element’s arc length to the angle that it subtends.
the component \( dE_x \) set up by \( ds \) as

\[
dE_x = dE \cos \theta = \frac{1}{4\pi\varepsilon_0} \frac{\lambda}{r} \cos \theta \, ds. \tag{22-20}
\]

Equation 22-20 has two variables, \( \theta \) and \( s \). Before we can integrate it, we must eliminate one variable. We do so by replacing \( ds \), using the relation

\[
ds = r \, d\theta,
\]

in which \( d\theta \) is the angle at \( P \) that includes arc length \( ds \) (Fig. 22-13g). With this replacement, we can integrate Eq. 22-20 over the angle made by the rod at \( P \), from \( \theta = -60^\circ \) to \( \theta = 60^\circ \); that will give us the field magnitude at \( P \):

\[
E = \int dE_x = \int_{-60^\circ}^{60^\circ} \frac{1}{4\pi\varepsilon_0} \frac{\lambda}{r} \cos \theta \, r \, d\theta
\]

\[
= \frac{\lambda}{4\pi\varepsilon_0 r} \left[ \sin \theta \right]_{-60^\circ}^{60^\circ}
\]

\[
= 1.73 \frac{\lambda}{4\pi\varepsilon_0 r}.
\tag{22-21}
\]

(If we had reversed the limits on the integration, we would have gotten the same result but with a minus sign. Since the integration gives only the magnitude of \( \vec{E} \), we would then have discarded the minus sign.)

**Charge density:** To evaluate \( \lambda \), we note that the full rod subtends an angle of 120° and so is one-third of a full circle. Its arc length is then \( 2\pi r/3 \), and its linear charge density must be

\[
\lambda = \frac{\text{charge}}{\text{length}} = \frac{Q}{2\pi r/3} = \frac{0.477Q}{r}.
\]

Substituting this into Eq. 22-21 and simplifying give us

\[
E = \frac{(1.73)(0.477Q)}{4\pi\varepsilon_0 r} = \frac{0.83Q}{4\pi\varepsilon_0 r^2}.
\]

(Answer)

The direction of \( \vec{E} \) is toward the rod, along the axis of symmetry of the charge distribution. We can write \( \vec{E} \) in unit-vector notation as

\[
\vec{E} = \frac{0.83Q}{4\pi\varepsilon_0 r^2} \hat{i}.
\]

**Problem-Solving Tactics**  A Field Guide for Lines of Charge

Here is a generic guide for finding the electric field \( \vec{E} \) produced at a point \( P \) by a line of uniform charge, either circular or straight. The general strategy is to pick out an element \( dq \) of the charge, find \( d\vec{E} \) due to that element, and integrate \( d\vec{E} \) over the entire line of charge.

**Step 1.** If the line of charge is circular, let \( ds \) be the arc length of an element of the distribution. If the line is straight, run an \( x \) axis along it and let \( dx \) be the length of an element. Mark the element on a sketch.

**Step 2.** Relate the charge \( dq \) of the element to the length of the element with either \( dq = \lambda \, ds \) or \( dq = \lambda \, dx \). Consider \( dq \) and \( \lambda \) to be positive, even if the charge is actually negative. (The sign of the charge is used in the next step.)

**Step 3.** Express the field \( d\vec{E} \) produced at \( P \) by \( dq \) with Eq. 22-3, replacing \( q \) in that equation with either \( \lambda \, ds \) or \( \lambda \, dx \). If the charge on the line is positive, then at \( P \) draw a vector \( d\vec{E} \) that points directly away from \( dq \). If the charge is negative, draw the vector pointing directly toward \( dq \).

**Step 4.** Always look for any symmetry in the situation. If \( P \) is on an axis of symmetry of the charge distribution, resolve the field \( d\vec{E} \) produced by \( dq \) into components that are perpendicular and parallel to the axis of symmetry. Then consider a second element \( dq' \) that is located symmetrically to \( dq \) about the line of symmetry. At \( P \) draw the vector \( d\vec{E}' \) that this symmetrical element produces and resolve it into components. One of the components produced by \( dq \) is a **cancelling component**; it is canceled by the corresponding component produced by \( dq' \) and needs no further attention. The other component produced by \( dq \) is an **adding component**; it adds to the corresponding component produced by \( dq' \). Add the adding components of all the elements via integration.

**Step 5.** Here are four general types of uniform charge distributions, with strategies for the integral of step 4.

*Ring,* with point \( P \) on (central) axis of symmetry, as in Fig. 22-11. In the expression for \( dE \), replace \( r^2 \) with \( z^2 + R^2 \), as in Eq. 22-12. Express the adding component of \( d\vec{E} \) in terms of \( \theta \). That introduces \( \cos \theta \), but \( \theta \) is identical for all elements and thus is not a variable. Replace \( \cos \theta \) as in Eq. 22-13. Integrate over \( s \), around the circumference of the ring.

*Circular arc,* with point \( P \) at the center of curvature, as in Fig. 22-13. Express the adding component of \( d\vec{E} \) in terms of \( \theta \). That introduces either \( \sin \theta \) or \( \cos \theta \). Reduce the resulting two variables \( s \) and \( \theta \) to one, \( \theta \), by replacing \( ds \) with \( r \, d\theta \). Integrate over \( \theta \) from one end of the arc to the other end.

*Straight line,* with point \( P \) on an extension of the line, as in Fig. 22-14a. In the expression for \( dE \), replace \( r \) with \( x \). Integrate over \( x \), from end to end of the line of charge.
**22-5 THE ELECTRIC FIELD DUE TO A CHARGED DISK**

**Learning Objectives**

*After reading this module, you should be able to . . .*

22.19 Sketch a disk with uniform charge and indicate the direction of the electric field at a point on the central axis if the charge is positive and if it is negative.

22.20 Explain how the equation for the electric field on the central axis of a uniformly charged disk can be used to find the equation for the electric field on the central axis of a uniformly charged disk.

22.21 For a point on the central axis of a uniformly charged disk, apply the relationship between the surface charge density \( \sigma \), the disk radius \( R \), and the distance \( z \) to that point.

**Key Idea**

- On the central axis through a uniformly charged disk,

\[
E = \frac{\sigma}{2\varepsilon_0} \left(1 - \frac{z}{\sqrt{z^2 + R^2}}\right)
\]

gives the electric field magnitude. Here \( z \) is the distance along the axis from the center of the disk, \( R \) is the radius of the disk, and \( \sigma \) is the surface charge density.

**The Electric Field Due to a Charged Disk**

Now we switch from a line of charge to a surface of charge by examining the electric field of a circular plastic disk, with a radius \( R \) and a uniform surface charge density \( \sigma \) (charge per unit area, Table 22-1) on its top surface. The disk sets up a
electric field at point $P$ and radial width $dr$. The ring shown has radius $r$ and uniform electric field $dE$ at point $P$ on its central axis.

**Figure 22-15** A disk of radius $R$ and uniform positive charge. The ring shown has radius $r$ and radial width $dr$. It sets up a differential electric field $dE$ at point $P$ on its central axis.

pattern of electric field lines around it, but here we restrict our attention to the electric field at an arbitrary point $P$ on the central axis, at distance $z$ from the center of the disk, as indicated in Fig. 22-15.

We could proceed as in the preceding module but set up a two-dimensional integral to include all of the field contributions from the two-dimensional distribution of charge on the top surface. However, we can save a lot of work with a neat shortcut using our earlier work with the field on the central axis of a thin ring.

We superimpose a ring on the disk as shown in Fig. 22-15, at an arbitrary radius $r \leq R$. The ring is so thin that we can treat the charge on it as a charge element $dq$. To find its small contribution $dE$ to the electric field at point $P$, we rewrite Eq. 22-16 in terms of the ring's charge $dq$ and radius $r$:

$$
    dE = \frac{dq \, z}{4 \pi \varepsilon_0 (z^2 + r^2)^{3/2}}.
$$

(22-22)

The ring's field points in the positive direction of the $z$ axis.

To find the total field at $P$, we are going to integrate Eq. 22-22 from the center of the disk at $r = 0$ out to the rim at $r = R$ so that we sum all the $dE$ contributions (by sweeping our arbitrary ring over the entire disk surface). However, that means we want to integrate with respect to a variable radius $r$ of the ring.

We get $dr$ into the expression by substituting for $dq$ in Eq. 22-22. Because the ring is so thin, call its thickness $dr$. Then its surface area $dA$ is the product of its circumference $2\pi r$ and thickness $dr$. So, in terms of the surface charge density $\sigma$, we have

$$
    dq = \sigma \, dA = \sigma (2\pi \, dr).
$$

(22-23)

After substituting this into Eq. 22-22 and simplifying slightly, we can sum all the $dE$ contributions with

$$
    E = \int dE = \frac{\sigma z}{4 \varepsilon_0} \int_0^R \left( z^2 + r^2 \right)^{-3/2} (2r) \, dr,
$$

(22-24)

where we have pulled the constants (including $z$) out of the integral. To solve this integral, we cast it in the form $\int X^m \, dX$ by setting $X = (z^2 + r^2)$, $m = -\frac{3}{2}$, and $dX = (2r) \, dr$. For the recast integral we have

$$
    \int X^m \, dX = \frac{X^{m+1}}{m+1},
$$

and so Eq. 22-24 becomes

$$
    E = \frac{\sigma z}{4 \varepsilon_0} \left[ \left( z^2 + r^2 \right)^{-1/2} \right]_0^R.
$$

(22-25)

Taking the limits in Eq. 22-25 and rearranging, we find

$$
    E = \frac{\sigma}{2 \varepsilon_0} \left( 1 - \frac{z}{\sqrt{z^2 + R^2}} \right) \quad \text{(charged disk)}
$$

(22-26)

as the magnitude of the electric field produced by a flat, circular, charged disk at points on its central axis. (In carrying out the integration, we assumed that $z \geq 0$.)

If we let $R \to \infty$ while keeping $z$ finite, the second term in the parentheses in Eq. 22-26 approaches zero, and this equation reduces to

$$
    E = \frac{\sigma}{2 \varepsilon_0} \quad \text{(infinite sheet)}.
$$

(22-27)

This is the electric field produced by an infinite sheet of uniform charge located on one side of a nonconductor such as plastic. The electric field lines for such a situation are shown in Fig. 22-4.

We also get Eq. 22-27 if we let $z \to 0$ in Eq. 22-26 while keeping $R$ finite. This shows that at points very close to the disk, the electric field set up by the disk is the same as if the disk were infinite in extent.
22-6 A POINT CHARGE IN AN ELECTRIC FIELD

Learning Objectives

After reading this module, you should be able to . . .

22.22 For a charged particle placed in an external electric field (a field due to other charged objects), apply the relationship between the electric field \( \vec{E} \) at that point, the particle’s charge \( q \), and the electrostatic force \( \vec{F} \) that acts on the particle, and identify the relative directions of the force and the field when the particle is positively charged and negatively charged.

22.23 Explain Millikan’s procedure of measuring the elementary charge.

22.24 Explain the general mechanism of ink-jet printing.

Key Ideas

- If a particle with charge \( q \) is placed in an external electric field \( \vec{E} \), an electrostatic force \( \vec{F} \) acts on the particle:
  \[
  \vec{F} = q\vec{E}.
  \]

- If charge \( q \) is positive, the force vector is in the same direction as the field vector. If charge \( q \) is negative, the force vector is in the opposite direction (the minus sign in the equation reverses the force vector from the field vector).

A Point Charge in an Electric Field

In the preceding four modules we worked at the first of our two tasks: given a charge distribution, to find the electric field it produces in the surrounding space. Here we begin the second task: to determine what happens to a charged particle when it is in an electric field set up by other stationary or slowly moving charges.

What happens is that an electrostatic force acts on the particle, as given by

\[
\vec{F} = q\vec{E},
\]

in which \( q \) is the charge of the particle (including its sign) and \( \vec{E} \) is the electric field that other charges have produced at the location of the particle. (The field is not the field set up by the particle itself; to distinguish the two fields, the field acting on the particle in Eq. 22-28 is often called the external field. A charged particle or object is not affected by its own electric field.) Equation 22-28 tells us

Measuring the Elementary Charge

Equation 22-28 played a role in the measurement of the elementary charge \( e \) by American physicist Robert A. Millikan in 1910–1913. Figure 22-16 is a representation of his apparatus. When tiny oil drops are sprayed into chamber A, some of them become charged, either positively or negatively, in the process. Consider a drop that drifts downward through the small hole in plate \( P_1 \) and into chamber C. Let us assume that this drop has a negative charge \( q \).

If switch \( S \) in Fig. 22-16 is open as shown, battery B has no electrical effect on chamber C. If the switch is closed (the connection between chamber C and the positive terminal of the battery is then complete), the battery causes an excess positive charge on conducting plate \( P_1 \) and an excess negative charge on conducting plate \( P_2 \). The charged plates set up a downward-directed electric field \( \vec{E} \) in chamber C. According to Eq. 22-28, this field exerts an electrostatic force on any charged drop that happens to be in the chamber and affects its motion. In particular, our negatively charged drop will tend to drift upward.

By timing the motion of oil drops with the switch opened and with it closed and thus determining the effect of the charge \( q \), Millikan discovered that the

![Figure 22-16 The Millikan oil-drop apparatus for measuring the elementary charge \( e \). When a charged oil drop drifted into chamber C through the hole in plate \( P_1 \), its motion could be controlled by closing and opening switch \( S \) and thereby setting up or eliminating an electric field in chamber C. The microscope was used to view the drop, to permit timing of its motion.](image-url)
values of $q$ were always given by

$$q = ne, \quad \text{for } n = 0, \pm 1, \pm 2, \pm 3, \ldots,$$

(22-29)

in which $e$ turned out to be the fundamental constant we call the elementary charge, $1.60 \times 10^{-19}$ C. Millikan’s experiment is convincing proof that charge is quantized, and he earned the 1923 Nobel Prize in physics in part for this work. Modern measurements of the elementary charge rely on a variety of interlocking experiments, all more precise than the pioneering experiment of Millikan.

**Ink-Jet Printing**

The need for high-quality, high-speed printing has caused a search for an alternative to impact printing, such as occurs in a standard typewriter. Building up letters by squirting tiny drops of ink at the paper is one such alternative.

Figure 22-17 shows a negatively charged drop moving between two conducting deflecting plates, between which a uniform, downward-directed electric field $\vec{E}$ has been set up. The drop is deflected upward according to Eq. 22-28 and then strikes the paper at a position that is determined by the magnitudes of $\vec{E}$ and the charge $q$ of the drop.

In practice, $E$ is held constant and the position of the drop is determined by the charge $q$ delivered to the drop in the charging unit, through which the drop must pass before entering the deflecting system. The charging unit, in turn, is activated by electronic signals that encode the material to be printed.

**Electrical Breakdown and Sparking**

If the magnitude of an electric field in air exceeds a certain critical value $E_c$, the air undergoes electrical breakdown, a process whereby the field removes electrons from the atoms in the air. The air then begins to conduct electric current because the freed electrons are propelled into motion by the field. As they move, they collide with any atoms in their path, causing those atoms to emit light. We can see the paths, commonly called sparks, taken by the freed electrons because of that emitted light. Figure 22-18 shows sparks above charged metal wires where the electric fields due to the wires cause electrical breakdown of the air.

**Checkpoint 3**

(a) In the figure, what is the direction of the electrostatic force on the electron due to the external electric field shown? (b) In which direction will the electron accelerate if it is moving parallel to the $y$ axis before it encounters the external field? (c) If, instead, the electron is initially moving rightward, will its speed increase, decrease, or remain constant?
Sample Problem 22.04  Motion of a charged particle in an electric field

Figure 22-19 shows the deflecting plates of an ink-jet printer, with superimposed coordinate axes. An ink drop with a mass \( m = 1.3 \times 10^{-10} \) kg and a negative charge of magnitude \( Q = 1.5 \times 10^{-13} \) C enters the region between the plates, initially moving along the \( x \) axis with speed \( v_x = 18 \) m/s. The length \( L \) of each plate is 1.6 cm. The plates are charged and thus produce an electric field at all points between them. Assume that field \( \vec{E} \) is downward directed, is uniform, and has a magnitude of 1.4 N/C. What is the vertical deflection of the drop at the far edge of the plates? (The gravitational force on the drop is small relative to the electrostatic force acting on the drop and can be neglected.)

**Calculations:** Applying Newton’s second law \( (F = ma) \) for components along the \( y \) axis, we find that

\[
a_y = \frac{F}{m} = \frac{QE}{m}.
\]

Let \( t \) represent the time required for the drop to pass through the region between the plates. During \( t \) the vertical and horizontal displacements of the drop are

\[
y = \frac{1}{2} a_y t^2 \quad \text{and} \quad L = v_x t,
\]

respectively. Eliminating \( t \) between these two equations and substituting Eq. 22-30 for \( a_y \), we find

\[
y = \frac{QEL^2}{2mv_x^2}
\]

\[
= \frac{(1.5 \times 10^{-13} \text{ C})(1.4 \times 10^6 \text{ N/C})(1.6 \times 10^{-2} \text{ m})^2}{(2)(1.3 \times 10^{-10} \text{ kg})(18 \text{ m/s})^2}
\]

\[
= 6.4 \times 10^{-4} \text{ m}
\]

\[
= 0.64 \text{ mm}. \quad \text{ (Answer)}
\]

22-7 A DIPOLE IN AN ELECTRIC FIELD

Learning Objectives

*After reading this module, you should be able to . . .*

22.25 On a sketch of an electric dipole in an external electric field, indicate the direction of the field, the direction of the dipole moment, the direction of the electrostatic forces on the two ends of the dipole, and the direction in which those forces tend to rotate the dipole, and identify the value of the net force on the dipole.

22.26 Calculate the torque on an electric dipole in an external electric field by evaluating a cross product of the dipole moment vector and the electric field vector, in magnitude-angle notation and unit-vector notation.

22.27 For an electric dipole in an external electric field, relate the potential energy of the dipole to the work done by a torque as the dipole rotates in the electric field.

22.28 For an electric dipole in an external electric field, calculate the potential energy by taking a dot product of the dipole moment vector and the electric field vector, in magnitude-angle notation and unit-vector notation.

22.29 For an electric dipole in an external electric field, identify the angles for the minimum and maximum potential energies and the angles for the minimum and maximum torque magnitudes.

**Key Ideas**

- The torque on an electric dipole of dipole moment \( \vec{p} \) when placed in an external electric field \( \vec{E} \) is given by a cross product:

\[
\vec{\tau} = \vec{p} \times \vec{E}.
\]

- A potential energy \( U \) is associated with the orientation of the dipole moment in the field, as given by a dot product:

\[
U = -\vec{p} \cdot \vec{E}.
\]

- If the dipole orientation changes, the work done by the electric field is

\[
W = -\Delta U.
\]

If the change in orientation is due to an external agent, the work done by the agent is

\[
W_\text{ext} = -W.
\]
A Dipole in an Electric Field

We have defined the electric dipole moment \( \vec{p} \) of an electric dipole to be a vector that points from the negative to the positive end of the dipole. As you will see, the behavior of a dipole in a uniform external electric field \( \vec{E} \) can be described completely in terms of the two vectors \( \vec{E} \) and \( \vec{p} \), with no need of any details about the dipole’s structure.

A molecule of water (H₂O) is an electric dipole; Fig. 22-20 shows why. There are two black dots representing the oxygen nuclei (having eight protons) and the two hydrogen nuclei (having one proton each). The colored enclosed areas represent the regions in which electrons can be located around the nuclei.

In a water molecule, the two hydrogen atoms and the oxygen atom do not lie on a straight line but form an angle of about 105°, as shown in Fig. 22-20. As a result, the molecule has a definite “oxygen side” and “hydrogen side.” Moreover, the 10 electrons of the molecule tend to remain closer to the oxygen nucleus than to the hydrogen nuclei. This makes the oxygen side of the molecule slightly more negative than the hydrogen side and creates an electric dipole moment \( \vec{p} \) that points along the symmetry axis of the molecule as shown. If the water molecule is placed in an external electric field, it behaves as would be expected of the more abstract electric dipole of Fig. 22-9.

To examine this behavior, we now consider such an abstract dipole in a uniform external electric field \( \vec{E} \), as shown in Fig. 22-21a. We assume that the dipole is a rigid structure that consists of two centers of opposite charge, each of magnitude \( q \), separated by a distance \( d \). The dipole moment \( \vec{p} \) makes an angle \( \theta \) with field \( \vec{E} \).

Electrostatic forces act on the charged ends of the dipole. Because the electric field is uniform, those forces act in opposite directions (as shown in Fig. 22-21a) and with the same magnitude \( F = qE \). Thus, because the field is uniform, the net force on the dipole from the field is zero and the center of mass of the dipole does not move. However, the forces on the charged ends do produce a net torque \( \vec{\tau} \) on the dipole about its center of mass. The center of mass lies on the line connecting the charged ends, at some distance \( x \) from one end and thus a distance \( d - x \) from the other end. From Eq. 10-39 \( (\tau = rF \sin \phi) \), we can write the magnitude of the net torque \( \vec{\tau} \) as

\[
\tau = Fx \sin \theta + F(d - x) \sin \theta = Fd \sin \theta. \quad (22-32)
\]

We can also write the magnitude of \( \vec{\tau} \) in terms of the magnitudes of the electric field \( E \) and the dipole moment \( p = qd \). To do so, we substitute \( qE \) for \( F \) and \( p/q \) for \( d \) in Eq. 22-32, finding that the magnitude of \( \vec{\tau} \) is

\[
\tau = pE \sin \theta. \quad (22-33)
\]

We can generalize this equation to vector form as

\[
\vec{\tau} = \vec{p} \times \vec{E} \quad \text{(torque on a dipole).} \quad (22-34)
\]

Vectors \( \vec{p} \) and \( \vec{E} \) are shown in Fig. 22-21b. The torque acting on a dipole tends to rotate \( \vec{p} \) (hence the dipole) into the direction of field \( \vec{E} \), thereby reducing \( \theta \). In Fig. 22-21, such rotation is clockwise. As we discussed in Chapter 10, we can represent a torque that gives rise to a clockwise rotation by including a minus sign with the magnitude of the torque. With that notation, the torque of Fig. 22-21 is

\[
\tau = -pE \sin \theta. \quad (22-35)
\]

Potential Energy of an Electric Dipole

Potential energy can be associated with the orientation of an electric dipole in an electric field. The dipole has its least potential energy when it is in its equilibrium orientation, which is when its moment \( \vec{p} \) is lined up with the field \( \vec{E} \) (then \( \tau = \vec{p} \times \vec{E} = 0 \)). It has greater potential energy in all other orientations. Thus the dipole is like a pendulum, which has its least gravitational potential
energy in *its* equilibrium orientation — at its lowest point. To rotate the dipole or the pendulum to any other orientation requires work by some external agent.

In any situation involving potential energy, we are free to define the zero-potential-energy configuration in an arbitrary way because only differences in potential energy have physical meaning. The expression for the potential energy of an electric dipole in an external electric field is simplest if we choose the potential energy to be zero when the angle $\theta$ in Fig. 22-21 is $90^\circ$. We then can find the potential energy $U$ of the dipole at any other value of $\theta$ with Eq. 8-1 ($\Delta U = -W$) by calculating the work $W$ done by the field on the dipole when the dipole is rotated to that value of $\theta$ from $90^\circ$. With the aid of Eq. 10-53 ($W = \int \tau \, d\theta$) and Eq. 22-35, we find that the potential energy $U$ at any angle $\theta$ is

$$ U = -W = -\int_{90^\circ}^{\theta} \tau \, d\theta = \int_{90^\circ}^{\theta} pE \sin \theta \, d\theta. \quad (22-36) $$

Evaluating the integral leads to

$$ U = -pE \cos \theta. \quad (22-37) $$

We can generalize this equation to vector form as

$$ U = -\vec{p} \cdot \vec{E} \quad \text{(potential energy of a dipole).} \quad (22-38) $$

Equations 22-37 and 22-38 show us that the potential energy of the dipole is least ($U = -pE$) when $\theta = 0$ ($\vec{p}$ and $\vec{E}$ are in the same direction); the potential energy is greatest ($U = pE$) when $\theta = 180^\circ$ ($\vec{p}$ and $\vec{E}$ are in opposite directions).

When a dipole rotates from an initial orientation $\theta_i$ to another orientation $\theta_f$, the work $W$ done on the dipole by the electric field is

$$ W = -\Delta U = -(U_f - U_i), \quad (22-39) $$

where $U_f$ and $U_i$ are calculated with Eq. 22-38. If the change in orientation is caused by an applied torque (commonly said to be due to an external agent), then the work $W_a$ done on the dipole by the applied torque is the negative of the work done on the dipole by the field; that is,

$$ W_a = -W = (U_f - U_i). \quad (22-40) $$

**Microwave Cooking**

Food can be warmed and cooked in a microwave oven if the food contains water because water molecules are electric dipoles. When you turn on the oven, the microwave source sets up a rapidly oscillating electric field $\vec{E}$ within the oven and thus also within the food. From Eq. 22-34, we see that any electric field $\vec{E}$ produces a torque on an electric dipole moment $\vec{p}$ to align $\vec{p}$ with $\vec{E}$. Because the oven’s $\vec{E}$ oscillates, the water molecules continuously flip-flop in a frustrated attempt to align with $\vec{E}$.

Energy is transferred from the electric field to the thermal energy of the water (and thus of the food) where three water molecules happened to have bonded together to form a group. The flip-flop breaks some of the bonds. When the molecules reform the bonds, energy is transferred to the random motion of the group and then to the surrounding molecules. Soon, the thermal energy of the water is enough to cook the food.

**Checkpoint 4**

The figure shows four orientations of an electric dipole in an external electric field. Rank the orientations according to (a) the magnitude of the torque on the dipole and (b) the potential energy of the dipole, greatest first.
Sample Problem 22.05  Torque and energy of an electric dipole in an electric field

A neutral water molecule (H\textsubscript{2}O) in its vapor state has an electric dipole moment of magnitude 6.2 \times 10^{-30} \text{C} \cdot \text{m}.

(a) How far apart are the molecule’s centers of positive and negative charge?

**KEY IDEA**

A molecule’s dipole moment depends on the magnitude \( q \) of the molecule’s positive or negative charge and the charge separation \( d \).

**Calculations:** There are 10 electrons and 10 protons in a neutral water molecule; so the magnitude of its dipole moment is

\[
p = qd = (10e)(d),
\]

in which \( d \) is the separation we are seeking and \( e \) is the elementary charge. Thus,

\[
d = \frac{p}{10e} = \frac{6.2 \times 10^{-30} \text{C} \cdot \text{m}}{(10)(1.60 \times 10^{-19} \text{C})} = 3.9 \times 10^{-12} \text{ m} = 3.9 \text{ pm}.
\]

This distance is not only small, but it is also actually smaller than the radius of a hydrogen atom.

(b) If the molecule is placed in an electric field of 1.5 \times 10^4 \text{ N/C}, what maximum torque can the field exert on it? (Such a field can easily be set up in the laboratory.)

**KEY IDEA**

The work done by an external agent (by means of a torque applied to the molecule) is equal to the change in the molecule’s potential energy due to the change in orientation.

**Calculation:** From Eq. 22-40, we find

\[
W_u = U_{180} - U_0 = (-pE \cos 180^\circ) - (-pE \cos 0) = 2pE = 2(6.2 \times 10^{-30} \text{ C} \cdot \text{m})(1.5 \times 10^4 \text{ N/C}) = 1.9 \times 10^{-25} \text{ J}.
\]

The direction of \( \vec{E} \) is away from the point charge if the charge is positive and toward it if the charge is negative.

**Field Due to an Electric Dipole** An electric dipole consists of two particles with charges of equal magnitude \( q \) but opposite sign, separated by a small distance \( d \). Their electric dipole moment \( \vec{p} \) has magnitude \( qd \) and points from the negative charge to the positive charge. The magnitude of the electric field set up by the dipole at a distant point on the dipole axis (which runs through both charges) is

\[
E = \frac{1}{2 \pi \epsilon_0} \frac{p}{z^2},
\]

where \( z \) is the distance between the point and the center of the dipole.

**Field Due to a Continuous Charge Distribution** The electric field due to a continuous charge distribution is found by treating charge elements as point charges and then summing, via integration, the electric field vectors produced by all the charge elements to find the net vector.
Field Due to a Charged Disk  The electric field magnitude at a point on the central axis through a uniformly charged disk is given by

\[ E = \frac{\sigma}{2\pi R} \left( 1 - \frac{z}{\sqrt{z^2 + R^2}} \right). \]  \hspace{1cm} (22-26)

where \( z \) is the distance along the axis from the center of the disk, \( R \) is the radius of the disk, and \( \sigma \) is the surface charge density.

Force on a Point Charge in an Electric Field  When a point charge \( q \) is placed in an external electric field \( \vec{E} \), the electrostatic force \( \vec{F} \) that acts on the point charge is

\[ \vec{F} = q\vec{E}. \]  \hspace{1cm} (22-28)

Questions

1. Figure 22-22 shows three arrangements of electric field lines. In each arrangement, a proton is released from rest at point \( P \) and is then accelerated through point \( B \) by the electric field. Points \( A \) and \( B \) have equal separations in the three arrangements. Rank the arrangements according to the linear momentum of the proton at point \( B \), greatest first.

\[ \text{Figure 22-22 Question 1.} \]

2. Figure 22-23 shows two square arrays of charged particles. The squares, which are centered on point \( P \), are misaligned. The particles are separated by either \( d \) or \( d/2 \) along the perimeters of the squares. What are the magnitude and direction of the electric field at \( P \)?

3. In Fig. 22-24, two particles of charge \(-q\) are arranged symmetrically about the \( y \) axis; each produces an electric field at point \( P \) on that axis. (a) Are the magnitudes of the fields at \( P \) equal? (b) Is each electric field directed toward or away from the charge producing it? (c) Is the magnitude of the net electric field at \( P \) equal to the sum of the magnitudes \( E \) of the two field vectors (is it equal to \( 2E \))? (d) Do the \( x \) components of those two field vectors add or cancel? (e) Do their \( y \) components add or cancel? (f) Do the direction of the net field at \( P \) that of the canceling components or the adding components? (g) What is the direction of the net field?

4. Figure 22-25 shows four situations in which four charged particles are evenly spaced to the left and right of a central point. The charge values are indicated. Rank the situations according to the magnitude of the field.

\[ \text{Figure 22-25 Question 4.} \]

5. Figure 22-26 shows two charged particles fixed in place on an axis. (a) Where on the axis (other than at an infinite distance) is there a point at which their net electric field is zero? Between the charges, to their left, or to their right? (b) Is there a point of zero net electric field anywhere off the axis (other than at an infinite distance)?

6. In Fig. 22-27, two identical circular nonconducting rings are centered on the same line with their planes perpendicular to the line. Each ring has charge that is uniformly distributed along its circumference. The rings each produce electric fields at points along the line. For three situations, the charges on rings \( A \) and \( B \) are, respectively, (1) \( +q_0 \) and \( -q_0 \), (2) \( +q_0 \) and \( -q_0 \), and (3) \( -q_0 \) and \( +q_0 \). Rank the situations according to the magnitude of the net electric field at (a) point \( P_1 \), midway between the rings, (b) point \( P_2 \) at the center of ring \( B \), and (c) point \( P_3 \) to the right of ring \( B \), greatest first.

7. The potential energies associated with four orientations of an electric dipole in an electric field are (1) \(-5U_0\), (2) \(-7U_0\), (3) \(3U_0\), and (4) \(5U_0\), where \( U_0 \) is positive. Rank the orientations according to (a) the angle between the electric dipole moment \( \vec{p} \) and the electric field \( \vec{E} \) and (b) the magnitude of the torque on the electric dipole, greatest first.

8. (a) In Checkpoint 4, if the dipole rotates from orientation 1 to orientation 2, is the work done on the dipole by the field positive, negative, or zero? (b) If, instead, the dipole rotates from orientation 1 to orientation 4, is the work done by the field more than, less than, or the same as in (a)?
9 Figure 22-28 shows two disks and a flat ring, each with the same uniform charge \( Q \). Rank the objects according to the magnitude of the electric field they create at points \( P \) (which are at the same vertical heights), greatest first.

![Figure 22-28](image1.png)

**Figure 22-28** Question 9.

10 In Fig. 22-29, an electron \( e \) travels through a small hole in plate \( A \) and then toward plate \( B \). A uniform electric field in the region between the plates then slows the electron without deflecting it. (a) What is the direction of the field? (b) Four other particles similarly travel through small holes in either plate \( A \) or plate \( B \) and then into the region between the plates. Three have charges \( +q_1 \), \( +q_2 \), and \( -q_2 \). The fourth (labeled \( n \)) is a neutron, which is electrically neutral. Does the speed of each of those four other particles increase, decrease, or remain the same in the region between the plates?

![Figure 22-29](image2.png)

**Figure 22-29** Question 10.

11 In Fig. 22-30a, a circular plastic rod with uniform charge \( +Q \) produces an electric field of magnitude \( E \) at the center of curvature (at the origin). In Figs. 22-30b, c, and d, more circular rods, each with identical uniform charges \( +Q \), are added until the circle is complete. A fifth arrangement (which would be labeled \( e \)) is like that in \( d \) except the rod in the fourth quadrant has charge \( -Q \). Rank the five arrangements according to the magnitude of the electric field at the center of curvature, greatest first.

![Figure 22-30](image3.png)

**Figure 22-30** Question 11.

12 When three electric dipoles are near each other, they each experience the electric field of the other two, and the three-dipole system has a certain potential energy. Figure 22-31 shows two arrangements in which three electric dipoles are side by side. Each dipole has the same magnitude of electric dipole moment, and the spacings between adjacent dipoles are identical. In which arrangement is the potential energy of the three-dipole system greater?

![Figure 22-31](image4.png)

**Figure 22-31** Question 12.

13 Figure 22-32 shows three rods, each with the same charge \( Q \) spread uniformly along its length. Rods \( a \) (of length \( L \)) and \( b \) (of length \( L/2 \)) are straight, and points \( P \) are aligned with their midpoints. Rod \( c \) (of length \( L/2 \)) forms a complete circle about point \( P \). Rank the rods according to the magnitude of the electric field they create at points \( P \), greatest first.

![Figure 22-32](image5.png)

**Figure 22-32** Question 13.

14 Figure 22-33 shows five protons that are launched in a uniform electric field \( E \); the magnitude and direction of the launch velocities are indicated. Rank the protons according to the magnitude of their accelerations due to the field, greatest first.

![Figure 22-33](image6.png)

**Figure 22-33** Question 14.
Module 22-2  The Electric Field Due to a Charged Particle

Two charged particles are fixed to an x axis: Particle 1 of charge \( +q = 3.20 \times 10^{-8} \text{ C} \) at position \( x = 6.00 \text{ cm} \) and particle 2 of charge \( -q = 3.20 \times 10^{-8} \text{ C} \) at position \( x = 21.0 \text{ cm} \). Midway between the particles, what is their net electric field in unit-vector notation?

What is the magnitude of a point charge that would create an electric field of 1.00 N/C at points 1.00 m away?

Figure 22-33 shows an un-even arrangement of electrons (e) and protons (p) on a circular arc of radius \( r = 2.00 \text{ cm} \), with angles \( \theta_1 = 30.0^\circ \), \( \theta_2 = 50.0^\circ \), \( \theta_3 = 30.0^\circ \), and \( \theta_4 = 20.0^\circ \). What are the (a) magnitude and (b) direction (relative to the positive direction of the x axis) of the net electric field produced by the two particles equal to zero?

Figure 22-40 shows a proton (p) on the central axis through a disk with a uniform charge density due to excess electrons. The disk is seen from an edge-on view. Three of those electrons are shown: electron \( e_1 \) at the disk center and electrons \( e_2 \) at opposite sides of the disk, at radius \( R \) from the center. The proton is initially at distance \( z = R = 2.00 \text{ cm} \) from the disk. At that location, what are the magnitudes of (a) the electric field \( \vec{E}_1 \) due to electron \( e_1 \), and (b) the net electric field \( \vec{E}_{\text{net,1}} \) due to electrons \( e_2 \)? The proton is then moved to \( z = R/10.0 \). What then are the magnitudes of (c) \( \vec{E}_1 \) and (d) \( \vec{E}_{\text{net,1}} \) at the proton’s location? (e) From (a) and (c) we see that as the proton gets nearer to the disk, the magnitude of \( \vec{E}_1 \) increases, as expected. Why does the magnitude of \( \vec{E}_{\text{net,1}} \) from the two side electrons decrease, as we see from (b) and (d)?

In Fig. 22-41, particle 1 of charge \( q_1 = -5.00q \) and particle 2 of charge \( q_2 = +2.00q \) are fixed to an x-axis. (a) As a multiple of distance \( L \), at what coordinate on the axis is the net electric field of the particles zero? (b) Sketch the net electric field lines between and around the particles.

In Fig. 22-34 the electric field lines on the left have twice the separation of those on the right. (a) If the magnitude of the field at \( A \) is 40 N/C, what is the magnitude of the force on a proton at \( A \)? (b) What is the magnitude of the force at \( B \)?

Two charged particles are attached to an x axis: Particle 1 of charge \( -2.00 \times 10^{-7} \text{ C} \) is at position \( x = 6.00 \text{ cm} \) and particle 2 of charge \( +2.00 \times 10^{-7} \text{ C} \) is at position \( x = 21.0 \text{ cm} \). Midway between the particles, what is their net electric field in unit-vector notation?

What is the magnitude of a point charge that would create an electric field of 1.00 N/C at points 1.00 m away?

In Fig. 22-35, the four particles form a square of edge length \( a = 5.00 \text{ cm} \) and have charges \( q_1 = +10.0 \text{ nC} \), \( q_2 = -20.0 \text{ nC} \), \( q_3 = +20.0 \text{ nC} \), and \( q_4 = -10.0 \text{ nC} \). In unit-vector notation, what net electric field do the particles produce at the square’s center?

In Fig. 22-36, the four particles are fixed in place and have charges \( q_1 = -q_2 = +5e \), \( q_3 = +3e \), and \( q_4 = -12e \). Distance \( d \) is 5.00 \text{ mm} . What is the magnitude of the net electric field at point \( P \) due to the particles?

Figure 22-37 shows two charged particles on an x axis: \( -q = -3.20 \times 10^{-19} \text{ C} \) at \( x = -3.00 \text{ m} \) and \( q = 3.20 \times 10^{-19} \text{ C} \) at \( x = +3.00 \text{ m} \). What are the (a) magnitude and (b) direction (relative to the positive direction of the x axis) of the net electric field produced at point \( P \) at \( y = 4.00 \text{ m} \)?

In Fig. 22-38a shows two charged particles fixed in place on an x axis with separation \( L \). The ratio \( q_1/q_2 \) of their charge magnitudes is 4.00. Figure 22-38b shows the x component \( E_{\text{net,x}} \) of their net electric field along the x axis just to the right of particle 2. The x axis scale is set by \( x_s = 30.0 \text{ cm} \). (a) At what value of \( x > 0 \) is \( E_{\text{net,x}} \) maximum? (b) If particle 2 has charge \( -q_2 = -3e \), what is the value of that maximum?
15 In Fig. 22-42, the three particles are fixed in place and have charges \( q_1 = q_2 = +2e \) and \( q_3 = +2e \). Distance \( a = 6.00 \, \mu\text{m} \). What are the (a) magnitude and (b) direction of the net electric field at point \( P \) due to the particles?

16 Figure 22-43 shows a plastic ring of radius \( R = 50.0 \, \text{cm} \). Two small charged beads are on the ring: Bead 1 of charge \( +2.00 \, \mu\text{C} \) is fixed in place at the left side; bead 2 of charge \( +6.00 \, \mu\text{C} \) can be moved along the ring. The two beads produce a net electric field of magnitude \( E \) at the center of the ring. At what (a) positive and (b) negative value of angle \( \theta \) should bead 2 be positioned such that \( E = 2.00 \times 10^4 \, \text{N/C} \)?

17 Two charged beads are on the plastic ring in Fig. 22-44a. Bead 2, which is not shown, is fixed in place on the ring, which has radius \( R = 60.0 \, \text{cm} \). Bead 1, which is not fixed in place, is initially on the \( x \) axis at angle \( \theta = 0^\circ \). It is then moved to the opposite side, at angle \( \theta = 180^\circ \), through the first and second quadrants of the \( xy \) coordinate system. Figure 22-44b gives the \( x \) component of the net electric field produced at the origin by the two beads as a function of \( \theta \), and Fig. 22-44c gives the \( y \) component of that net electric field. The vertical axis scales are set by \( E_{xy} = 5.00 \times 10^4 \, \text{N/C} \) and \( E_{yy} = -9.00 \times 10^4 \, \text{N/C} \). (a) At what angle \( \theta \) is bead 2 located? What are the charges of (b) bead 1 and (c) bead 2?

![Figure 22-44](image)

18 The electric field of an electric dipole along the dipole axis is approximated by Eqs. 22-8 and 22-9. If a binomial expansion is made of Eq. 22-7, what is the next term in the expression for the dipole’s electric field along the dipole axis? That is, what is \( E_{\text{next}} \) in the expression

\[
E = \frac{1}{2\pi\epsilon_0} \frac{qd}{r^3} + E_{\text{next}}
\]

19 Figure 22-45 shows an electric dipole. What are the (a) magnitude and (b) direction (relative to the positive direction of the \( x \) axis) of the dipole’s electric field at point \( P \), located at distance \( r \gg d \)?

![Figure 22-45](image)

20 Equations 22-8 and 22-9 are approximations of the magnitude of the electric field of an electric dipole, at points along the dipole axis. Consider a point \( P \) on that axis at distance \( z = 5.00d \) from the dipole center (\( d \) is the separation distance between the particles of the dipole). Let \( E_{\text{appr}} \) be the magnitude of the field at point \( P \) as approximated by Eqs. 22-8 and 22-9. Let \( E_{\text{act}} \) be the actual magnitude. What is the ratio \( E_{\text{appr}} / E_{\text{act}} \)?

21 **SSM** Electric quadrupole. Figure 22-46 shows a generic electric quadrupole. It consists of two dipoles with dipole moments that are equal in magnitude but opposite in direction. Show that the value of \( E \) on the axis of the quadrupole for a point \( P \) a distance \( z \) from its center (assume \( z \gg d \)) is given by

\[
E = \frac{3Q}{4\pi\epsilon_0 z^4},
\]

in which \( Q \) \((= 2qd^2)\) is known as the quadrupole moment of the charge distribution.

Module 22-4 The Electric Field Due to a Line of Charge

22 Density, density, density. (a) A charge \(-300e\) is uniformly distributed along a circular arc of radius 4.00 cm, which subtends an angle of 40°. What is the linear charge density along the arc? (b) A charge \(-300e\) is uniformly distributed over one face of a circular disk of radius 2.00 cm. What is the surface charge density over that face? (c) A charge \(-300e\) is uniformly distributed over the surface of a sphere of radius 2.00 cm. What is the surface charge density over that surface? (d) A charge \(-300e\) is uniformly spread through the volume of a sphere of radius 2.00 cm. What is the volume charge density in that sphere?

23 Figure 22-47 shows two parallel nonconducting rings with their central axes along a common line. Ring 1 has uniform charge \( q_1 \) and radius \( R \); ring 2 has uniform charge \( q_2 \) and the same radius \( R \). The rings are separated by distance \( d = 3.00R \). The net electric field at point \( P \) on the common line, at distance \( R \) from ring 1, is zero. What is the ratio \( q_1/q_2 \)?

24 A thin nonconducting rod with a uniform distribution of positive charge \( Q \) is bent into a complete circle of radius \( R \).
(Fig. 22-48). The central perpendicular axis through the ring is a \( z \) axis, with the origin at the center of the ring. What is the magnitude of the electric field due to the rod at (a) \( z = 0 \) and (b) \( z = \infty \)? (c) In terms of \( R \), at what positive value of \( z \) is that magnitude maximum? (d) If \( R = 2.00 \text{ cm} \) and \( Q = 4.00 \mu \text{C} \), what is the maximum magnitude?

**Problem 25** Figure 22-49 shows three circular arcs centered on the origin of a coordinate system. On each arc, the uniformly distributed charge is given in terms of \( Q = 2.00 \mu \text{C} \). The radii are given in terms of \( R = 10.0 \text{ cm} \). What are the (a) magnitude and (b) direction (relative to the positive \( x \) direction) of the net electric field at the origin due to the arcs?

**Problem 26** In Fig. 22-50, a thin glass rod forms a semicircle of radius \( r = 5.00 \text{ cm} \). Charge is uniformly distributed along the rod, with \( +q = 4.50 \text{ pC} \) in the upper half and \( -q = -4.50 \text{ pC} \) in the lower half. What are the (a) magnitude and (b) direction (relative to the positive direction of the \( x \) axis) of the electric field \( \vec{E} \) at \( P \), the center of the semicircle?

**Problem 27** In Fig. 22-51, two curved plastic rods, one of charge \( +q \) and the other of charge \( -q \), form a circle of radius \( R = 8.50 \text{ cm} \) in an \( xy \) plane. The \( x \) axis passes through both of the connecting points, and the charge is distributed uniformly on both rods. If \( q = 15.0 \text{ pC} \), what are the (a) magnitude and (b) direction (relative to the positive direction of the \( x \) axis) of the electric field \( \vec{E} \) produced at \( P \), the center of the circle?

**Problem 28** Charge is uniformly distributed around a ring of radius \( R = 2.40 \text{ cm} \), and the resulting electric field magnitude \( E \) is measured along the ring’s central axis (perpendicular to the plane of the ring). At what distance from the ring’s center is \( E \) maximum?

**Problem 29** Figure 22-52a shows a nonconducting rod with a uniformly distributed charge \( +Q \). The rod forms a half-circle with radius \( R \) and produces an electric field of magnitude \( E_{\text{rod}} \) at its center of curvature \( P \). If the arc is collapsed to a point at distance \( R \) from \( P \) (Fig. 22-52b), by what factor is the magnitude of the electric field at \( P \) multiplied?

**Problem 30** Figure 22-53 shows two concentric rings, of radii \( R \) and \( R' = 3.00R \), that lie on the same plane. Point \( P \) lies on the central \( z \) axis, at distance \( D = 2.00R \) from the center of the rings. The smaller ring has uniformly distributed charge \( +Q \). In terms of \( Q \), what is the uniformly distributed charge on the larger ring if the net electric field at \( P \) is zero?

**Problem 31** In Fig. 22-54, a nonconducting rod of length \( L = 8.15 \text{ cm} \) has a charge \( -q = -4.23 \mu \text{C} \) uniformly distributed along its length. (a) What is the linear charge density of the rod? What are the (b) magnitude and (c) direction (relative to the positive direction of the \( x \) axis) of the electric field produced at point \( P \), at distance \( a = 12.0 \text{ cm} \) from the rod? What is the electric field magnitude produced at distance \( a = 50 \text{ m} \) by (d) the rod and (e) a particle of charge \( -q = -4.23 \mu \text{C} \) that we use to replace the rod? (At that distance, the rod “looks” like a particle.)

**Problem 32** In Fig. 22-55, positive charge \( q = 7.81 \text{ pC} \) is spread uniformly along a thin nonconducting rod of length \( L = 14.5 \text{ cm} \). What are the (a) magnitude and (b) direction (relative to the positive direction of the \( x \) axis) of the electric field produced at point \( P \), at distance \( R = 6.00 \text{ cm} \) from the rod along its perpendicular bisector?

**Problem 33** In Fig. 22-56, a “semi-infinite” nonconducting rod (that is, infinite in one direction only) has uniform linear charge density \( \lambda \). Show that the electric field \( \vec{E}_p \) at point \( P \) makes an angle of 45° with the rod and that this result is independent of the distance \( R \). (Hint: Separately find the component of \( \vec{E}_p \) parallel to the rod and the component perpendicular to the rod.)

**Module 22-5 The Electric Field Due to a Charged Disk**

**Problem 34** A disk of radius 2.5 cm has a surface charge density of 5.3 \( \mu \text{C/m}^2 \) on its upper face. What is the magnitude of the electric field produced by the disk at a point on its central axis at distance \( z = 12 \text{ cm} \) from the disk?

**Problem 35** At what distance along the central perpendicular axis of a uniformly charged plastic disk of radius 0.600 m is the magnitude of the electric field equal to one-half the magnitude of the field at the center of the surface of the disk?

**Problem 36** A circular plastic disk with radius \( R = 2.00 \text{ cm} \) has a uniformly distributed charge \( Q = +(2.00 \times 10^{-9}) \mu \text{C} \) on one face. A circular ring of width 30 \( \mu \text{m} \) is centered on that face, with the center of that width at radius \( r = 0.50 \text{ cm} \). In coulombs, what charge is contained within the width of the ring?
•37 Suppose you design an apparatus in which a uniformly charged disk of radius \( R \) is to produce an electric field. The field magnitude is most important along the central perpendicular axis of the disk, at a point \( P \) at distance 2.00\( R \) from the disk (Fig. 22-57a). Cost analysis suggests that you switch to a ring of the same outer radius \( R \) but with inner radius \( R/2.00 \) (Fig. 22-57b). Assume that the ring will have the same surface charge density as the original disk. If you switch to the ring, by what percentage will you decrease the electric field magnitude at \( P \)?

•40 An electron with a speed of 5.00 \( \times 10^6 \) cm/s enters an electric field of magnitude 1.00 \( \times 10^5 \) N/C, traveling along a field line in the direction that retards its motion. (a) How far will the electron travel in the field before stopping momentarily, and (b) how much time will have elapsed? (c) If the region containing the electric field is 8.00 mm long (too short for the electron to stop within it), what fraction of the electron’s initial kinetic energy will be lost in that region?

•43 SSM An electron is released from rest in a uniform electric field of magnitude 2.00 \( \times 10^3 \) N/C. Calculate the acceleration of the electron. (Ignore gravitation.)

•44 An alpha particle (the nucleus of a helium atom) has a mass of 6.64 \( \times 10^{-27} \) kg and a charge of \(+2e\). What are the (a) magnitude and (b) direction of the electric field that will balance the gravitational force on the particle?

•45 ILW An electron on the axis of an electric dipole is 25 nm from the center of the dipole. What is the magnitude of the electrostatic force on the electron if the dipole moment is 3.6 \( \times 10^{-30} \) C⋅m? Assume that 25 nm is much larger than the separation of the charged particles that form the dipole.

•46 An electron is accelerated eastward at 1.80 \( \times 10^4 \) m/s^2 by an electric field. Determine the field (a) magnitude and (b) direction.

•47 SSM Beams of high-speed protons can be produced in “guns” using electric fields to accelerate the protons. (a) What acceleration would a proton experience if the gun’s electric field were 2.00 \( \times 10^4 \) N/C? (b) What speed would the proton attain if the gun accelerated the proton through a distance of 1.00 cm?

•48 In Fig. 22-59, an electron (e) is to be released from rest on the central axis of a uniformly charged disk of radius \( R \). The surface charge density on the disk is +4.00 \( \mu \)C/m^2. What is the magnitude of the electron’s initial acceleration if it is released at a distance (a) \( R \), (b) \( R/100 \), and (c) \( R/1000 \) from the center of the disk? (d) Why does the acceleration magnitude increase only slightly as the release point is moved closer to the disk?

•49 A 10.0 g block with a charge of \(+8.00 \times 10^{-5} \) C is placed in an electric field \( \vec{E} = (3000\hat{i} - 600\hat{j}) \) N/C. What are the (a) magnitude and (b) direction (relative to the positive direction of the x axis) of the electrostatic force on the block? If the block is released from rest at the origin at time \( t = 0 \), what are its (c) x and (d) y coordinates at \( t = 3.00 \) s?

•50 At some instant the velocity components of an electron moving between two charged parallel plates are \( v_x = 1.5 \times 10^4 \) m/s and \( v_y = 3.0 \times 10^3 \) m/s. Suppose the electric field between the plates is uniform and given by \( \vec{E} = (120 \text{ N/C})\hat{j} \). In unit-vector notation, what are (a) the electron’s acceleration in that field and (b) the electron’s velocity when its x coordinate has changed by 2.0 cm?

•51 SSM Assume that a honeybee is a sphere of diameter 1.000 cm with a charge of +45.0 pC uniformly spread over its surface. Assume also that a spherical pollen grain of diameter 40.0 \( \mu \)m is electrically held on the surface of the bee because the bee’s charge induces a charge of \(-1.00 \text{ pC} \) on the near side of the grain and a charge of \(+1.00 \text{ pC} \) on the far side. (a) What is the magnitude of the net electrostatic force on the grain due to the bee? Next, assume that the bee brings the grain to a distance of 1.000 mm from the tip of a flower’s stigma and that the tip is a particle of charge \(-45.0 \text{ pC} \). (b) What is the magnitude of the net electrostatic force on the grain due to the stigma? (c) Does the grain remain on the bee or does it move to the stigma?

•52 An electron enters a region of uniform electric field with an initial velocity of 40 km/s in the same direction as the electric field, which has magnitude \( E = 50 \) N/C. (a) What is the speed of the electron 1.5 ns after entering this region? (b) How far does the electron travel during the 1.5 ns interval?
Two large parallel copper plates are 5.0 cm apart and have a uniform electric field between them as depicted in Fig. 22-60. An electron is released from the negative plate at the same time that a proton is released from the positive plate. Neglect the force of the particles on each other and find their distance from the positive plate when they pass each other. (Does it surprise you that you need not know the electric field to solve this problem?)

In Fig. 22-61, an electron is shot at an initial speed of \( v_0 = 2.00 \times 10^6 \) m/s, at angle \( \theta_0 = 40.0^\circ \) from an x axis. It moves through a uniform electric field \( \vec{E} = (5.00 \text{ N/C})\hat{j} \). A screen for detecting electrons is positioned parallel to the y axis, at distance \( x = 3.00 \) m. In unit-vector notation, what is the velocity of the electron when it hits the screen?

A uniform electric field exists in a region between two oppositely charged plates. An electron is released from rest at the surface of the negatively charged plate and strikes the surface of the opposite plate, 2.0 cm away, in a time \( 1.5 \times 10^{-5} \) s. (a) What is the speed of the electron as it strikes the second plate? (b) What is the magnitude of the electric field \( \vec{E} \)?

An electric dipole consists of charges +2e and −2e separated by 0.78 nm. It is in an electric field of strength \( 3.4 \times 10^5 \) N/C. Calculate the magnitude of the torque on the dipole when the dipole moment is (a) parallel to, (b) perpendicular to, and (c) antiparallel to the electric field.

An electric dipole consisting of charges of magnitude 1.50 nC separated by 6.20 \( \mu \)m is in an electric field of strength 1100 N/C. What are (a) the magnitude of the electric dipole moment and (b) the difference between the potential energies for dipole orientations parallel and antiparallel to \( \vec{E} \)?

A certain electric dipole is placed in a uniform electric field \( \vec{E} \) of magnitude 20 N/C. Figure 22-62 gives the potential energy \( U \) of the dipole versus the angle \( \theta \) between \( \vec{E} \) and the dipole moment \( \vec{p} \). The vertical axis scale is set by \( U_j = 100 \times 10^{-28} \) J. What is the magnitude of \( \vec{p} \)?

How much work is required to turn an electric dipole 180° in a uniform electric field of magnitude \( E = 46.0 \text{ N/C} \) if the dipole moment has a magnitude of \( p = 3.02 \times 10^{-25} \text{ C} \cdot \text{m} \) and the initial angle is 64°?

A certain electric dipole is placed in a uniform electric field \( \vec{E} \) of magnitude 40 N/C. Figure 22-63 gives the magnitude \( \tau \) of the torque on the dipole versus the angle \( \theta \) between \( \vec{E} \) and the dipole moment \( \vec{p} \). The vertical axis scale is set by \( \tau_i = 100 \times 10^{-28} \text{ N} \cdot \text{m} \). What is the magnitude of \( \vec{p} \)?

Find an expression for the oscillation frequency of an electric dipole of dipole moment \( \vec{p} \) and rotational inertia \( I \) for small amplitudes of oscillation about its equilibrium position in a uniform electric field of magnitude \( E \).

(a) What is the magnitude of an electron’s acceleration in a uniform electric field of magnitude \( 1.40 \times 10^6 \) N/C? (b) How long would the electron take, starting from rest, to attain one-tenth the speed of light? (c) How far would it travel in that time?

A spherical water drop 1.20 \( \mu \)m in diameter is suspended in calm air due to a downward-directed atmospheric electric field of magnitude \( E = 462 \text{ N/C} \). (a) What is the magnitude of the gravitational force on the drop? (b) How many excess electrons does it have?

Three particles, each with positive charge \( Q \), form an equilateral triangle, with each side of length \( d \). What is the magnitude of the electric field produced by the particles at the midpoint of any side?

In Fig. 22-64a, a particle of charge \( +Q \) produces an electric field of magnitude \( E_{\text{out}} \) at point \( P \), at distance \( R \) from the particle. In Fig. 22-64b, that same amount of charge is spread uniformly along a circular arc that has radius \( R \) and subtends an angle \( \theta \). The charge on the arc produces an electric field of magnitude \( E_{\text{arc}} \) at its center of curvature \( P \). For what value of \( \theta \) does \( E_{\text{arc}} = 0.500E_{\text{out}} \)? (Hint: You will probably resort to a graphical solution.)

A proton and an electron form two corners of an equilateral triangle of side length \( 2.0 \times 10^{-6} \) m. What is the magnitude of the net electric field these two particles produce at the third corner?

A charge (uniform linear density = 9.0 nC/m) lies on a string that is stretched along an x axis from \( x = 0 \) to \( x = 3.0 \) m. Determine the magnitude of the electric field at \( x = 4.0 \) m on the x axis.

In Fig. 22-65, eight particles form a square in which distance \( d = 2.0 \) cm. The charges are \( q_1 = +3e \), \( q_2 = +e \), \( q_3 = -5e \), \( q_4 = -2e \), \( q_5 = +3e \), \( q_6 = +e \), \( q_7 = -5e \), and \( q_8 = +e \). In unit-vector notation, what is the net electric field at the square’s center?

Two particles, each with a charge of magnitude 12 nC, are at two of the vertices of an equilateral triangle with edge length 2.0 m. What is the magnitude of the electric field at the third vertex if (a) both charges are positive and (b) one charge is positive and the other is negative?

The following table gives the charge seen by Millikan at different times on a single drop in his experiment. From the data, calculate the elementary charge \( e \).

71 A charge of 20 nC is uniformly distributed along a straight rod of length 4.0 m that is bent into a circular arc with a radius of 2.0 m. What is the magnitude of the electric field at the center of curvature of the arc?

72 An electron is constrained to the central axis of the ring of charge of radius \( R \) in Fig. 22-11, with \( z \ll R \). Show that the electrostatic force on the electron can cause it to oscillate through the ring center with an angular frequency

\[
\omega = \sqrt{\frac{eq}{4\pi\varepsilon_0 m R^2}},
\]

where \( q \) is the ring's charge and \( m \) is the electron's mass.

73 SSM The electric field in an \( xy \) plane produced by a positively charged particle is \( 7.2(4.0\hat{i} + 3.0\hat{j}) \) N/C at the point \((3.0, 3.0)\) cm and 100\( \varepsilon_0 \) N/C at the point \((2.0, 0)\) cm. What are the \( x \) and \( y \) coordinates of the particle? (c) What is the charge of the particle?

(a) What total (excess) charge \( q \) must the disk in Fig. 22-15 have for the electric field on the surface of the disk at its center to have magnitude \( 3.0 \times 10^6 \) N/C, the \( E \) value at which air breaks down electrically, producing sparks? Take the disk radius as 2.5 cm. (b) Suppose each surface atom has an effective cross-sectional area of 0.015 nm\(^2\). How many atoms are needed to make up the disk surface? (c) The charge calculated in (a) results from some of the surface atoms having one excess electron. What fraction of these atoms must be so charged?

74 In Fig. 22-66, particle 1 (of charge +1.00 \( \mu \)C), particle 2 (of charge +1.00 \( \mu \)C), and particle 3 (of charge \( Q \)) form an equilateral triangle of edge length \( a \). For what value of \( Q \) (both sign and magnitude) does the net electric field produced by the particles at the center of the triangle vanish?

75 In Fig. 22-66, particle 1 (of charge +1.00 \( \mu \)C), particle 2 (of charge +1.00 \( \mu \)C), and particle 3 (of charge \( Q \)) form an equilateral triangle of edge length \( a \). For what value of \( Q \) (both sign and magnitude) does the net electric field produced by the particles at the center of the triangle vanish?

76 In Fig. 22-67, an electric dipole swings from an initial orientation \( i \) (\( \theta_i = 20.0^\circ \)) to a final orientation \( f \) (\( \theta_f = 20.0^\circ \)) in a uniform external electric field \( E \). The electric dipole moment is \( 1.60 \times 10^{-27} \) C\( \cdot \)m; the field magnitude is \( 3.00 \times 10^9 \) N/C. What is the change in the dipole’s potential energy?

77 A particle of charge \(-q_i\) is at the origin of an \( x \) axis. (a) At what location on the axis should a particle of charge \(-4q_i\) be placed so that the net electric field is zero at \( x = 2.0 \) mm on the axis? (b) If, instead, a particle of charge \(+4q_i\) is placed at that location, what is the direction (relative to the positive direction of the \( x \) axis) of the net electric field at \( x = 2.0 \) mm?

78 Two particles, each of positive charge \( q \), are fixed in place on a \( y \) axis, one at \( y = d \) and the other at \( y = -d \). (a) Write an expression that gives the magnitude \( E \) of the net electric field at points on the \( x \) axis given by \( x = ad \). (b) Graph \( E \) versus \( \alpha \) for the range \( 0 < \alpha < 4 \). A. From the graph, determine the values of \( \alpha \) that give (c) the maximum value of \( E \) and (d) half the maximum value of \( E \).

79 A clock face has negative point charges \(-q, -2q, -3q, \ldots, -12q\) fixed at the positions of the corresponding numerals. The clock hands do not perturb the net field due to the point charges. At what time does the hour hand point in the same direction as the electric field vector at the center of the dial? (Hint: Use symmetry.)

80 Calculate the electric dipole moment of an electron and a proton 4.30 nm apart.

81 An electric field \( \vec{E} \) with an average magnitude of about 150 N/C points downward in the atmosphere near Earth’s surface. We wish to “float” a sulfur sphere weighing 4.4 N in this field by charging the sphere. (a) What charge (both sign and magnitude) must be used? (b) Why is the experiment impractical?

82 A circular rod has a radius of curvature \( R = 9.00 \) cm and a uniformly distributed positive charge \( Q = 6.25 \) pC and subtends an angle \( \theta = 2.40 \) rad. What is the magnitude of the electric field that \( Q \) produces at the center of curvature?

83 SSM An electric dipole with dipole moment

\[
\vec{p} = (3.00\hat{i} + 4.00\hat{j})(1.24 \times 10^{-30} \text{C} \cdot \text{m})
\]

is in an electric field \( \vec{E} = (4000 \text{N/C})\hat{j} \). (a) What is the potential energy of the electric dipole? (b) What is the torque acting on it? (c) If an external agent turns the dipole until its electric dipole moment is

\[
\vec{p} = (-4.00\hat{i} + 3.00\hat{j})(1.24 \times 10^{-30} \text{C} \cdot \text{m}),
\]

how much work is done by the agent?

84 In Fig. 22-68, a uniform, upward electric field \( \vec{E} \) of magnitude \( 2.00 \times 10^5 \) N/C has been set up between two horizontal plates by charging the lower plate positively and the upper plate negatively. The plates have length \( L = 10.0 \) cm and separation \( d = 2.00 \) cm. An electron is then shot between the plates from the left edge of the lower plate. The initial velocity \( v_0 \) of the electron makes an angle \( \theta = 45.0^\circ \) with the lower plate and has a magnitude of \( 6.00 \times 10^6 \) m/s. (a) Will the electron strike one of the plates? (b) If so, which plate and how far horizontally from the left edge will the electron strike?

85 For the data of Problem 70, assume that the charge \( q \) on the drop is given by \( q = ne \), where \( n \) is an integer and \( e \) is the elementary charge. (a) Find \( n \) for each given value of \( q \). (b) Do a linear regression fit of the values of \( q \) versus the values of \( n \) and then use that fit to find \( e \).

86 In Fig. 22-66, particle 1 (of charge +2.00 pC), particle 2 (of charge \(-2.00 \) pC), and particle 3 (of charge +5.00 pC) form an equilateral triangle of edge length \( a = 9.50 \) cm. (a) Relative to the positive direction of the \( x \) axis, determine the direction of the force \( \vec{F}_2 \) on particle 3 due to the other particles by sketching electric field lines of the other particles. (b) Calculate the magnitude of \( \vec{F}_3 \).

87 In Fig. 22-69, particle 1 of charge \( q_1 = 1.00 \) pC and particle 2 of charge \( q_2 = -2.00 \) pC are fixed at a distance \( d = 5.00 \) cm apart. In unit-vector notation, what is the net electric field at points (a) \( A \), (b) \( B \), and (c) \( C \)? (d) Sketch the electric field lines.
CHAPTER 23
Gauss’ Law

23-1 ELECTRIC FLUX

Learning Objectives

After reading this module, you should be able to . . .

23.01 Identify that Gauss’ law relates the electric field at points on a closed surface (real or imaginary, said to be a Gaussian surface) to the net charge enclosed by that surface.

23.02 Identify that the amount of electric field piercing a surface (not skimming along the surface) is the electric flux \( \Phi \) through the surface.

23.03 Identify that an area vector for a flat surface is a vector that is perpendicular to the surface and that has a magnitude equal to the area \( dA \) of the element.

23.04 Identify that any surface can be divided into area elements (patch elements) that are each small enough and flat enough for an area vector \( dA \) to be assigned to it, with the vector perpendicular to the element and having a magnitude equal to the area of the element.

23.05 Calculate the flux \( \Phi \) through a surface by integrating the dot product of the electric field vector \( \vec{E} \) and the area vector \( dA \) (for patch elements) over the surface, in magnitude-angle notation and unit-vector notation.

23.06 For a closed surface, explain the algebraic signs associated with inward flux and outward flux.

23.07 Calculate the net flux \( \Phi \) through a closed surface, algebraic sign included, by integrating the dot product of the electric field vector \( \vec{E} \) and the area vector \( dA \) (for patch elements) over the full surface.

23.08 Determine whether a closed surface can be broken up into parts (such as the sides of a cube) to simplify the integration that yields the net flux through the surface.

Key Ideas

- The electric flux \( \Phi \) through a surface is the amount of electric field that pierces the surface.
- The area vector \( dA \) for an area element (patch element) on a surface is a vector that is perpendicular to the element and has a magnitude equal to the area \( dA \) of the element.
- The electric flux \( d\Phi \) through a patch element with area vector \( dA \) is given by a dot product:
  \[ d\Phi = \vec{E} \cdot dA, \]
- The total flux through a surface is given by
  \[ \Phi = \int \vec{E} \cdot dA \] (total flux),
  where the integration is carried out over the surface.
- The net flux through a closed surface (which is used in Gauss’ law) is given by
  \[ \Phi = \oint \vec{E} \cdot dA \] (net flux),
  where the integration is carried out over the entire surface.

What Is Physics?

In the preceding chapter we found the electric field at points near extended charged objects, such as rods. Our technique was labor-intensive: We split the charge distribution up into charge elements \( dq \), found the field \( d\vec{E} \) due to an element, and resolved the vector into components. Then we determined whether the components from all the elements would end up canceling or adding. Finally we summed the adding components by integrating over all the elements, with several changes in notation along the way.

One of the primary goals of physics is to find simple ways of solving such labor-intensive problems. One of the main tools in reaching this goal is the use of symmetry. In this chapter we discuss a beautiful relationship between charge and
electric field that allows us, in certain symmetric situations, to find the electric field of an extended charged object with a few lines of algebra. The relationship is called Gauss’ law, which was developed by German mathematician and physicist Carl Friedrich Gauss (1777–1855).

Let’s first take a quick look at some simple examples that give the spirit of Gauss’ law. Figure 23-1 shows a particle with charge \( Q \) that is surrounded by an imaginary concentric sphere. At points on the sphere (said to be a Gaussian surface), the electric field vectors have a moderate magnitude (given by \( E = kQ/r^2 \)) and point radially away from the particle (because it is positively charged). The electric field lines are also outward and have a moderate density (which, recall, is related to the field magnitude). We say that the field vectors and the field lines pierce the surface.

Figure 23-2 is similar except that the enclosed particle has charge \( 2Q \). Because the enclosed charge is now twice as much, the magnitude of the field vectors piercing outward through the (same) Gaussian surface is twice as much as in Fig. 23-1, and the density of the field lines is also twice as much. That sentence, in a nutshell, is Gauss’ law.

Gauss’ law relates the electric field at points on a (closed) Gaussian surface to the net charge enclosed by that surface.

Let’s check this with a third example with a particle that is also enclosed by the same spherical Gaussian surface (a Gaussian sphere, if you like, or even the catchy G-sphere) as shown in Fig. 23-3. What is the amount and sign of the enclosed charge? Well, from the inward piercing we see immediately that the charge must be negative. From the fact that the density of field lines is half that of Fig. 23-1, we also see that the charge must be \( 0.5Q \). (Using Gauss’ law is like being able to tell what is inside a gift box by looking at the wrapping paper on the box.)

The problems in this chapter are of two types. Sometimes we know the charge and we use Gauss’ law to find the field at some point. Sometimes we know the field on a Gaussian surface and we use Gauss’ law to find the charge enclosed by the surface. However, we cannot do all this by simply comparing the density of field lines in a drawing as we just did. We need a quantitative way of determining how much electric field pierces a surface. That measure is called the electric flux.

**Electric Flux**

**Flat Surface, Uniform Field.** We begin with a flat surface with area \( A \) in a uniform electric field \( \vec{E} \). Figure 23-4a shows one of the electric field vectors \( \vec{E} \) piercing a small square patch with area \( \Delta A \) (where \( \Delta \) indicates “small”). Actually, only the \( x \) component (with magnitude \( E_x = E \cos \theta \) in Fig. 23-4b) pierces the patch. The \( y \) component merely skims along the surface (no piercing in that) and does not come into play in Gauss’ law. The amount of electric field piercing the patch is defined to be the electric flux \( \Delta \Phi \) through it:

\[
\Delta \Phi = (E \cos \theta) \Delta A.
\]
There is another way to write the right side of this statement so that we have only the piercing component of \( \vec{E} \). We define an area vector \( \Delta \vec{A} \) that is perpendicular to the patch and that has a magnitude equal to the area \( \Delta A \) of the patch (Fig. 23-4c). Then we can write

\[
\Delta \Phi = \vec{E} \cdot \Delta \vec{A},
\]

and the dot product automatically gives us the component of \( \vec{E} \) that is parallel to \( \Delta \vec{A} \) and thus piercing the patch.

To find the total flux \( \Phi \) through the surface in Fig. 23-4, we sum the flux through every patch on the surface:

\[
\Phi = \sum \vec{E} \cdot \Delta \vec{A}.
\]  

(23-1)

However, because we do not want to sum hundreds (or more) flux values, we transform the summation into an integral by shrinking the patches from small squares with area \( \Delta A \) to patch elements (or area elements) with area \( dA \). The total flux is then

\[
\Phi = \int \vec{E} \cdot d\vec{A} \quad \text{(total flux).} 
\]  

(23-2)

Now we can find the total flux by integrating the dot product over the full surface.

**Dot Product.** We can evaluate the dot product inside the integral by writing the two vectors in unit-vector notation. For example, in Fig. 23-4, \( d\vec{A} = dA\hat{u} \) and \( \vec{E} \) might be, say, \((4\hat{i} + 4\hat{j}) \text{ N/C}\). Instead, we can evaluate the dot product in magnitude-angle notation: \( E \cos \theta \, dA \). When the electric field is uniform and the surface is flat, the product \( E \cos \theta \) is a constant and comes outside the integral. The remaining \( \int dA \) is just an instruction to sum the areas of all the patch elements to get the total area, but we already know that the total area is \( A \). So the total flux in this simple situation is

\[
\Phi = (E \cos \theta)A \quad \text{(uniform field, flat surface).} 
\]  

(23-3)

**Closed Surface.** To use Gauss’ law to relate flux and charge, we need a closed surface. Let’s use the closed surface in Fig. 23-5 that sits in a nonuniform electric field. (Don’t worry. The homework problems involve less complex surfaces.) As before, we first consider the flux through small square patches. However, now we are interested in not only the piercing components of the field but also on whether the piercing is inward or outward (just as we did with Figs. 23-1 through 23-3).

**Directions.** To keep track of the piercing direction, we again use an area vector \( \Delta \vec{A} \) that is perpendicular to a patch, but now we always draw it pointing outward from the surface (away from the interior). Then if a field vector pierces outward, it and the area vector are in the same direction, the angle is \( \theta = 0 \), and \( \cos \theta = 1 \). Thus, the dot product \( \vec{E} \cdot \Delta \vec{A} \) is positive and so is the flux. Conversely, if a field vector pierces inward, the angle is \( \theta = 180^\circ \) and \( \cos \theta = -1 \). Thus, the dot product is negative and so is the flux. If a field vector skims the surface (no piercing), the dot product is zero (because \( \cos 90^\circ = 0 \)) and so is the flux. Figure 23-5 gives some general examples and here is a summary:

- **Star:** An inward piercing field is negative flux. An outward piercing field is positive flux. A skimming field is zero flux.

**Net Flux.** In principle, to find the net flux through the surface in Fig. 23-5, we find the flux at every patch and then sum the results (with the algebraic signs included). However, we are not about to do that much work. Instead, we shrink the squares to patch elements with area vectors \( d\vec{A} \) and then integrate:

\[
\Phi = \oint \vec{E} \cdot d\vec{A} \quad \text{(net flux).} 
\]  

(23-4)

**Figure 23-5** A Gaussian surface of arbitrary shape immersed in an electric field. The surface is divided into small squares of area \( \Delta A \). The electric field vectors \( \vec{E} \) and the area vectors \( \Delta \vec{A} \) for three representative squares, marked 1, 2, and 3, are shown.
The loop on the integral sign indicates that we must integrate over the entire closed surface, to get the net flux through the surface (as in Fig. 23-5, flux might enter on one side and leave on another side). Keep in mind that we want to determine the net flux through a surface because that is what Gauss’ law relates to the charge enclosed by the surface. (The law is coming up next.) Note that flux is a scalar (yes, we talk about field vectors but flux is the amount of piercing field, not a vector itself). The SI unit of flux is the newton–square-meter per coulomb (N·m²/C).

Checkpoint 1

Sample Problem 23.01  Flux through a closed cylinder, uniform field

Figure 23-6 shows a Gaussian surface in the form of a closed cylinder (a Gaussian cylinder or G-cylinder) of radius $R$. It lies in a uniform electric field $\vec{E}$ with the cylinder’s central axis (along the length of the cylinder) parallel to the field. What is the net flux $\Phi$ of the electric field through the cylinder?

**KEY IDEAS**

We can find the net flux $\Phi$ with Eq. 23-4 by integrating the dot product $\vec{E} \cdot d\vec{A}$ over the cylinder’s surface. However, we cannot write out functions so that we can do that with one integral. Instead, we need to be a bit clever: We break up the surface into sections with which we can actually evaluate an integral.

**Calculations:** We break the integral of Eq. 23-4 into three terms: integrals over the left cylinder cap $a$, the curved cylindrical surface $b$, and the right cap $c$:

$$\Phi = \int \vec{E} \cdot d\vec{A} = \int_a \vec{E} \cdot d\vec{A} + \int_b \vec{E} \cdot d\vec{A} + \int_c \vec{E} \cdot d\vec{A}. \quad (23-5)$$

Pick a patch element on the left cap. Its area vector $d\vec{A}$ must be perpendicular to the patch and pointing away from the interior of the cylinder. In Fig. 23-6, that means the angle between it and the field piercing the patch is $180^\circ$. Also note that the electric field through the end cap is uniform and thus $E$ can be pulled out of the integration. So, we can write the flux through the left cap as

$$\int_a \vec{E} \cdot d\vec{A} = \int_a E \cos(180^\circ) \, dA = -E \int_a dA = -EA,$$

where $\int dA$ gives the cap’s area $A$ ($= \pi R^2$). Similarly, for the right cap, where $\theta = 0$ for all points,

$$\int_c \vec{E} \cdot d\vec{A} = \int_c E \cos(0) \, dA = EA.$$

Finally, for the cylindrical surface, where the angle $\theta$ is $90^\circ$ at all points,

$$\int_b \vec{E} \cdot d\vec{A} = \int_b E \cos(90^\circ) \, dA = 0.$$

Substituting these results into Eq. 23-5 leads us to

$$\Phi = -EA + 0 + EA = 0. \quad \text{(Answer)}$$

The net flux is zero because the field lines that represent the electric field all pass entirely through the Gaussian surface, from the left to the right.
**Sample Problem 23.02  Flux through a closed cube, nonuniform field**

A nonuniform electric field given by $\vec{E} = 3.0\hat{x} + 4.0\hat{y}$ pierces the Gaussian cube shown in Fig. 23-7a. ($E$ is in newtons per coulomb and $x$ is in meters.) What is the electric flux through the right face, the left face, and the top face? (We consider the other faces in another sample problem.)

**KEY IDEA**

We can find the flux $\Phi$ through the surface by integrating the scalar product $\vec{E} \cdot d\vec{A}$ over each face.

**Right face:** An area vector $\vec{A}$ is always perpendicular to its surface and always points away from the interior of a Gaussian surface. Thus, the vector $d\vec{A}$ for any patch element (small section) on the right face of the cube must point in the positive direction of the $x$ axis. An example of such an element is shown in Figs. 23-7b and c, but we would have an identical vector for any other choice of a patch element on that face. The most convenient way to express the vector is in unit-vector notation,

$$d\vec{A} = dA\hat{i}.$$  

From Eq. 23-4, the flux $\Phi_r$ through the right face is then

$$\Phi_r = \int \vec{E} \cdot d\vec{A} = \int (3.0\hat{x} + 4.0\hat{y}) \cdot (dA\hat{i})$$

$$= \int [(3.0)(dA)\hat{i} \cdot \hat{i} + (4.0)(dA)\hat{j} \cdot \hat{i}]$$

$$= \int (3.0x dA + 0) = 3.0 \int x \, dA.$$  

We are about to integrate over the right face, but we note that $x$ has the same value everywhere on that face — namely, $x = 3.0$ m. This means we can substitute that constant value for $x$. This can be a confusing argument. Although $x$ is certainly a variable as we move left to right across the figure, because the right face is perpendicular to the $x$ axis, every point on the face has the same $x$ coordinate. (The $y$ and $z$ coordinates do not matter in our integral.) Thus, we have

$$\Phi_r = 3.0 \int (3.0) \, dA = 9.0 \int \, dA.$$  

The integral $\int \, dA$ merely gives us the area $A = 4.0 \, m^2$ of the right face, so

$$\Phi_r = (9.0 \, \text{N/C})(4.0 \, \text{m}^2) = 36 \, \text{N} \cdot \text{m}^2/\text{C}. \quad \text{(Answer)}$$

**Left face:** We repeat this procedure for the left face. However,
Gauss' Law relates the net flux of an electric field through a closed surface to the net charge enclosed by that surface. It tells us that

\[ \Phi = \oint E \cdot dA = \epsilon_0 q_{\text{enc}} \quad \text{(Gauss' law)} \]

where \( \Phi \) is the net flux through the surface, \( E \) is the electric field, \( dA \) is the differential area vector, \( \epsilon_0 \) is the permittivity of free space, and \( q_{\text{enc}} \) is the net charge enclosed by the surface.
By substituting Eq. 23-4, the definition of flux, we can also write Gauss’ law as

\[ E_0 \int \vec{E} \cdot d\vec{A} = q_{\text{enc}} \]  \hspace{1cm} \text{(Gauss’ law)}  \hspace{1cm} (23-7)

Equations 23-6 and 23-7 hold only when the net charge is located in a vacuum or (what is the same for most practical purposes) in air. In Chapter 25, we modify Gauss’ law to include situations in which a material such as mica, oil, or glass is present.

In Eqs. 23-6 and 23-7, the net charge \( q_{\text{enc}} \) is the algebraic sum of all the enclosed positive and negative charges, and it can be positive, negative, or zero. We include the sign, rather than just use the magnitude of the enclosed charge, because the sign tells us something about the net flux through the Gaussian surface: If \( q_{\text{enc}} \) is positive, the net flux is outward; if \( q_{\text{enc}} \) is negative, the net flux is inward.

Charge outside the surface, no matter how large or how close it may be, is not included in the term \( q_{\text{enc}} \) in Gauss’ law. The exact form and location of the charges inside the Gaussian surface are also of no concern; the only things that matter on the right side of Eqs. 23-6 and 23-7 are the magnitude and sign of the net enclosed charge. The quantity \( \vec{E} \) on the left side of Eq. 23-7, however, is the electric field resulting from all charges, both those inside and those outside the Gaussian surface. This statement may seem to be inconsistent, but keep this in mind: The electric field due to a charge outside the Gaussian surface contributes zero net flux through the surface, because as many field lines due to that charge enter the surface as leave it.

Let us apply these ideas to Fig. 23-8, which shows two particles, with charges equal in magnitude but opposite in sign, and the field lines that represent their net electric field. Four Gaussian surfaces are also shown, in cross section. Let us consider each in turn.

**Surface \( S_1 \).** The electric field is outward for all points on this surface. Thus, the flux of the electric field through this surface is positive, and so is the net charge within the surface, as Gauss’ law requires. (That is, in Eq. 23-6, if \( \Phi \) is positive, \( q_{\text{enc}} \) must be also.)

**Surface \( S_2 \).** The electric field is inward for all points on this surface. Thus, the flux of the electric field through this surface is negative and so is the enclosed charge, as Gauss’ law requires.

**Surface \( S_3 \).** This surface encloses no charge, and thus \( q_{\text{enc}} = 0 \). Gauss’ law (Eq. 23-6) requires that the net flux of the electric field through this surface be zero. That is reasonable because all the field lines pass entirely through the surface, entering it at the top and leaving at the bottom.

**Surface \( S_4 \).** This surface encloses no net charge, because the enclosed positive and negative charges have equal magnitudes. Gauss’ law requires that the net flux of the electric field through this surface be zero. That is reasonable because there are as many field lines leaving surface \( S_4 \) as entering it.

What would happen if we were to bring an enormous charge \( Q \) up close to surface \( S_4 \) in Fig. 23-8? The pattern of the field lines would certainly change, but the net flux for each of the four Gaussian surfaces would not change. Thus, the value of \( Q \) would not enter Gauss’ law in any way, because \( Q \) lies outside all four of the Gaussian surfaces that we are considering.

**Checkpoint 2**

The figure shows three situations in which a Gaussian cube sits in an electric field. The arrows and the values indicate the directions of the field lines and the magnitudes (in N \( \cdot \) m\(^2\)/C) of the flux through the six sides of each cube. (The lighter arrows are for the hidden faces.) In which situation does the cube enclose (a) a positive net charge, (b) a negative net charge, and (c) zero net charge?
Gauss’ Law and Coulomb’s Law

One of the situations in which we can apply Gauss’ law is in finding the electric field of a charged particle. That field has spherical symmetry (the field depends on the distance \( r \) from the particle but not the direction). So, to make use of that symmetry, we enclose the particle in a Gaussian sphere that is centered on the particle, as shown in Fig. 23-9 for a particle with positive charge \( q \). Then the electric field has the same magnitude \( E \) at any point on the sphere (all points are at the same distance \( r \)). That feature will simplify the integration.

The drill here is the same as previously. Pick a patch element on the surface and draw its area vector \( d\mathbf{A} \) perpendicular to the patch and directed outward. From the symmetry of the situation, we know that the electric field \( \mathbf{E} \) at the patch is also radially outward and thus at angle \( \theta = 0 \) with \( d\mathbf{A} \). So, we rewrite Gauss’ law as

\[
\varepsilon_0 \oint \mathbf{E} \cdot d\mathbf{A} = \oint E \, dA = q_{\text{enc}}.
\]

(23-8)

Here \( q_{\text{enc}} = q \). Because the field magnitude \( E \) is the same at every patch element, \( E \) can be pulled outside the integral:

\[
\varepsilon_0 E \oint dA = q.
\]

(23-9)

The remaining integral is just an instruction to sum all the areas of the patch elements on the sphere, but we already know that the total area is \( 4\pi r^2 \). Substituting this, we have

\[
\varepsilon_0 E (4\pi r^2) = q
\]

or

\[
E = \frac{q}{4\pi \varepsilon_0} r^2.
\]

(23-10)

This is exactly Eq. 22-3, which we found using Coulomb’s law.

**Checkpoint 3**

There is a certain net flux \( \Phi \), through a Gaussian sphere of radius \( r \) enclosing an isolated charged particle. Suppose the enclosing Gaussian surface is changed to (a) a larger Gaussian sphere, (b) a Gaussian cube with edge length equal to \( r \), and (c) a Gaussian cube with edge length equal to \( 2r \). In each case, is the net flux through the new Gaussian surface greater than, less than, or equal to \( \Phi \)?

**Sample Problem 23.03 Using Gauss’ law to find the electric field**

Figure 23-10a shows, in cross section, a plastic, spherical shell with uniform charge \( Q = -16e \) and radius \( R = 10 \text{ cm} \). A particle with charge \( q = +5e \) is at the center. What is the electric field (magnitude and direction) at (a) point \( P_1 \) at radial distance \( r_1 = 6.00 \text{ cm} \) and (b) point \( P_2 \) at radial distance \( r_2 = 12.0 \text{ cm} \)?

**KEY IDEAS**

1. Because the situation in Fig. 23-10a has spherical symmetry, we can apply Gauss’ law (Eq. 23-7) to find the electric field at a point if we use a Gaussian surface in the form of a sphere concentric with the particle and shell.
2. To find the electric field at a point, we put that point on a Gaussian surface (so that the \( \mathbf{E} \) we want is the \( \mathbf{E} \) in the dot product inside the integral in Gauss’ law).
3. Gauss’ law relates the net electric flux through a closed surface to the net enclosed charge. Any external charge is not included.

**Calculations:** To find the field at point \( P_1 \), we construct a Gaussian sphere with \( P_1 \) on its surface and thus with a radius of \( r_1 \). Because the charge enclosed by the Gaussian sphere is positive, the electric flux through the surface must be positive and thus outward. So, the electric field \( \mathbf{E} \) pierces the surface outward and, because of the spherical symmetry, must be radially outward, as drawn in Fig. 23-10b. That figure does not include the plastic shell because the shell is not enclosed by the Gaussian sphere.

Consider a patch element on the sphere at \( P_1 \). Its area vector \( d\mathbf{A} \) is radially outward (it must always be outward from a Gaussian surface). Thus the angle \( \theta \) between \( \mathbf{E} \) and \( d\mathbf{A} \) is zero. We can now rewrite the left side of Eq. 23-7 (Gauss’ law) as

\[
\varepsilon_0 \oint \mathbf{E} \cdot d\mathbf{A} = \varepsilon_0 \oint E \cos 0 \, dA = \varepsilon_0 \oint E \, dA = \varepsilon_0 E \oint dA,
\]
where in the last step we pull the field magnitude $E$ out of the integral because it is the same at all points on the Gaussian sphere and thus is a constant. The remaining integral is simply an instruction for us to sum the areas of all the patch elements on the sphere, but we already know that the surface area of a sphere is $4\pi r^2$. Substituting these results, Eq. 23-7 for Gauss’ law gives us

$$\varepsilon_0 E 4\pi r^2 = q_{\text{enc}}.$$

The only charge enclosed by the Gaussian surface through $P_1$ is that of the particle. Solving for $E$ and substituting $q_{\text{enc}} = 5e$ and $r = r_1 = 6.00 \times 10^{-2}$ m, we find that the magnitude of the electric field at $P_1$ is

$$E = \frac{q_{\text{enc}}}{4\pi\varepsilon_0 r^2} = \frac{5(1.60 \times 10^{-19} \text{ C})}{4\pi(8.85 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2)(0.0600 \text{ m})^2} = 2.00 \times 10^{-6} \text{ N/C}. \quad (\text{Answer})$$

To find the electric field at $P_2$, we follow the same procedure by constructing a Gaussian sphere with $P_2$ on its surface. This time, however, the net charge enclosed by the sphere is $q_{\text{enc}} = q + Q = 5e + (−16e) = −11e$. Because the net charge is negative, the electric field vectors on the sphere’s surface pierce inward (Fig. 23-10c), the angle $\theta$ between $\vec{E}$ and $d\vec{A}$ is 180°, and the dot product is $E (\cos 180°) \ d\vec{A} = −E \ d\vec{A}$. Now solving Gauss’ law for $E$ and substituting $r = r_2 = 12.00 \times 10^{-2}$ m and the new $q_{\text{enc}}$, we find

$$E = \frac{-q_{\text{enc}}}{4\pi\varepsilon_0 r^2} = \frac{-[-11(1.60 \times 10^{-19} \text{ C})]}{4\pi(8.85 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2)(0.120 \text{ m})^2} = 1.10 \times 10^{-6} \text{ N/C}. \quad (\text{Answer})$$

Note how different the calculations would have been if we had put $P_1$ or $P_2$ on the surface of a Gaussian cube instead of mimicking the spherical symmetry with a Gaussian sphere. Then angle $\theta$ and magnitude $E$ would have varied considerably over the surface of the cube and evaluation of the integral in Gauss’ law would have been difficult.

**Sample Problem 23.04 Using Gauss’ law to find the enclosed charge**

What is the net charge enclosed by the Gaussian cube of Sample Problem 23.02?

**KEY IDEA**

The net charge enclosed by a (real or mathematical) closed surface is related to the total electric flux through the surface by Gauss’ law as given by Eq. 23-6 ($\varepsilon_0 \Phi = q_{\text{enc}}$).

**Flux:** To use Eq. 23-6, we need to know the flux through all six faces of the cube. We already know the flux through the right face ($\Phi_2 = 36 \text{ N} \cdot \text{m}^2/\text{C}$), the left face ($\Phi_1 = −12 \text{ N} \cdot \text{m}^2/\text{C}$), and the top face ($\Phi_t = 16 \text{ N} \cdot \text{m}^2/\text{C}$).

For the bottom face, our calculation is just like that for the top face except that the element area vector $d\vec{A}$ is now directed downward along the $y$ axis (recall, it must be outward from the Gaussian enclosure). Thus, we have $d\vec{A} = −d\vec{A}_j$, and we find $\Phi_b = −16 \text{ N} \cdot \text{m}^2/\text{C}$.

For the front face we have $d\vec{A} = d\vec{A}_k$, and for the back face, $d\vec{A} = −d\vec{A}_k$. When we take the dot product of the given electric field $\vec{E} = 3.0\hat{x} + 4.0\hat{y}$ with either of these expressions for $d\vec{A}$, we get 0 and thus there is no flux through those faces. We can now find the total flux through the six sides of the cube:

$$\Phi = (36 − 12 + 16 − 16 + 0 + 0) \text{ N} \cdot \text{m}^2/\text{C} = 24 \text{ N} \cdot \text{m}^2/\text{C}.$$

**Enclosed charge:** Next, we use Gauss’ law to find the charge $q_{\text{enc}}$ enclosed by the cube:

$$q_{\text{enc}} = \varepsilon_0 \Phi = (8.85 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2)(24 \text{ N} \cdot \text{m}^2/\text{C}) = 2.1 \times 10^{-10} \text{ C}. \quad (\text{Answer})$$

Thus, the cube encloses a net positive charge.
23-3 A CHARGED ISOLATED CONDUCTOR

Learning Objectives

After reading this module, you should be able to . . .

23.14 Apply the relationship between surface charge density \( \sigma \) and the area over which the charge is uniformly spread.
23.15 Identify that if excess charge (positive or negative) is placed on an isolated conductor, that charge moves to the surface and none is in the interior.
23.16 Identify the value of the electric field inside an isolated conductor.
23.17 For a conductor with a cavity that contains a charged object, determine the charge on the cavity wall and on the external surface.
23.18 Explain how Gauss’ law is used to find the electric field magnitude \( E \) near an isolated conducting surface with a uniform surface charge density \( \sigma \).
23.19 For a uniformly charged conducting surface, apply the relationship between the charge density \( \sigma \) and the electric field magnitude \( E \) at points near the conductor, and identify the direction of the field vectors.

Key Ideas

- An excess charge on an isolated conductor is located entirely on the outer surface of the conductor.
- The internal electric field of a charged, isolated conductor is zero, and the external field (at nearby points) is perpendicular to the surface and has a magnitude that depends on the surface charge density \( \sigma \):

\[
E = \frac{\sigma}{\varepsilon_0}.
\]

A Charged Isolated Conductor

Gauss’ law permits us to prove an important theorem about conductors:

\[ \text{If an excess charge is placed on an isolated conductor, that amount of charge will move entirely to the surface of the conductor. None of the excess charge will be found within the body of the conductor.} \]

This might seem reasonable, considering that charges with the same sign repel one another. You might imagine that, by moving to the surface, the added charges are getting as far away from one another as they can. We turn to Gauss’ law for verification of this speculation.

Figure 23-11a shows, in cross section, an isolated lump of copper hanging from an insulating thread and having an excess charge \( q \). We place a Gaussian surface just inside the actual surface of the conductor.

The electric field inside this conductor must be zero. If this were not so, the field would exert forces on the conduction (free) electrons, which are always present in a conductor, and thus current would always exist within a conductor. (That is, charge would flow from place to place within the conductor.) Of course, there is no such perpetual current in an isolated conductor, and so the internal electric field is zero.

(An internal electric field \textit{does} appear as a conductor is being charged. However, the added charge quickly distributes itself in such a way that the net internal electric field—the vector sum of the electric fields due to all the charges, both inside and outside—is zero. The movement of charge then ceases, because the net force on each charge is zero; the charges are then in \textit{electrostatic equilibrium}.)

If \( \vec{E} \) is zero everywhere inside our copper conductor, it must be zero for all points on the Gaussian surface because that surface, though close to the surface of the conductor, is definitely inside the conductor. This means that the flux through the Gaussian surface must be zero. Gauss’ law then tells us that the net charge inside the Gaussian surface must also be zero. Then because the excess charge is not inside the Gaussian surface, it must be outside that surface, which means it must lie on the actual surface of the conductor.

\[ \text{Figure 23-11 (a) A lump of copper with a charge } q \text{ hangs from an insulating thread. A Gaussian surface is placed within the metal, just inside the actual surface. (b) The lump of copper now has a cavity within it. A Gaussian surface lies within the metal, close to the cavity surface.} \]
An Isolated Conductor with a Cavity

Figure 23-11b shows the same hanging conductor, but now with a cavity that is totally within the conductor. It is perhaps reasonable to suppose that when we scoop out the electrically neutral material to form the cavity, we do not change the distribution of charge or the pattern of the electric field that exists in Fig. 23-11a. Again, we must turn to Gauss’ law for a quantitative proof.

We draw a Gaussian surface surrounding the cavity, close to its surface but inside the conducting body. Because \( \vec{E} = 0 \) inside the conductor, there can be no flux through this new Gaussian surface. Therefore, from Gauss’ law, that surface can enclose no net charge. We conclude that there is no net charge on the cavity walls; all the excess charge remains on the outer surface of the conductor, as in Fig. 23-11a.

The Conductor Removed

Suppose that, by some magic, the excess charges could be “frozen” into position on the conductor’s surface, perhaps by embedding them in a thin plastic coating, and suppose that then the conductor could be removed completely. This is equivalent to enlarging the cavity of Fig. 23-11b until it consumes the entire conductor, leaving only the charges. The electric field would not change at all; it would remain zero inside the thin shell of charge and would remain unchanged for all external points. This shows us that the electric field is set up by the charges and not by the conductor. The conductor simply provides an initial pathway for the charges to take up their positions.

The External Electric Field

You have seen that the excess charge on an isolated conductor moves entirely to the conductor’s surface. However, unless the conductor is spherical, the charge does not distribute itself uniformly. Put another way, the surface charge density \( \sigma \) (charge per unit area) varies over the surface of any nonspherical conductor. Generally, this variation makes the determination of the electric field set up by the surface charges very difficult.

However, the electric field just outside the surface of a conductor is easy to determine using Gauss’ law. To do this, we consider a section of the surface that is small enough to permit us to neglect any curvature and thus to take the section to be flat. We then imagine a tiny cylindrical Gaussian surface to be partially embedded in the section as shown in Fig. 23-12: One end cap is fully inside the conductor, the other is fully outside, and the cylinder is perpendicular to the conductor’s surface.

The electric field \( \vec{E} \) at and just outside the conductor’s surface must also be perpendicular to that surface. If it were not, then it would have a component along the conductor’s surface that would exert forces on the surface charges, causing them to move. However, such motion would violate our implicit assumption that we are dealing with electrostatic equilibrium. Therefore, \( \vec{E} \) is perpendicular to the conductor’s surface.

We now sum the flux through the Gaussian surface. There is no flux through the internal end cap, because the electric field within the conductor is zero. There is no flux through the curved surface of the cylinder, because internally (in the conductor) there is no electric field and externally the electric field is parallel to the curved portion of the Gaussian surface. The only flux through the Gaussian surface is that through the external end cap, where \( \vec{E} \) is perpendicular to the plane of the cap. We assume that the cap area \( A \) is small enough that the field magnitude \( E \) is constant over the cap. Then the flux through the cap is \( EA \), and that is the net flux \( \Phi \) through the Gaussian surface.

The charge \( q_{\text{enc}} \) enclosed by the Gaussian surface lies on the conductor’s surface in an area \( A \). (Think of the cylinder as a cookie cutter.) If \( \sigma \) is the charge per unit area, then \( q_{\text{enc}} \) is equal to \( \sigma A \). When we substitute \( \sigma A \) for \( q_{\text{enc}} \) and \( EA \) for \( \Phi \),
Gauss’ law (Eq. 23-6) becomes

\[ \epsilon_0 E A = \alpha A, \]

from which we find

\[ E = \frac{\alpha}{\epsilon_0} \quad \text{(conducting surface).} \quad (23-11) \]

Thus, the magnitude of the electric field just outside a conductor is proportional to the surface charge density on the conductor. The sign of the charge gives us the direction of the field. If the charge on the conductor is positive, the electric field is directed away from the conductor as in Fig. 23-12. It is directed toward the conductor if the charge is negative.

The field lines in Fig. 23-12 must terminate on negative charges somewhere in the environment. If we bring those charges near the conductor, the charge density at any given location on the conductor’s surface changes, and so does the magnitude of the electric field. However, the relation between \( \sigma \) and \( E \) is still given by Eq. 23-11.

**Sample Problem 23.05  Spherical metal shell, electric field and enclosed charge**

Figure 23-13a shows a cross section of a spherical metal shell of inner radius \( R \). A particle with a charge of \(-5.0 \, \mu\text{C}\) is located at a distance \( R/2 \) from the center of the shell. If the shell is electrically neutral, what are the (induced) charges on its inner and outer surfaces? Are those charges uniformly distributed? What is the field pattern inside and outside the shell?

**KEY IDEAS**

Figure 23-13b shows a cross section of a spherical Gaussian surface within the metal, just outside the inner wall of the shell. The electric field must be zero inside the metal (and thus on the Gaussian surface inside the metal). This means that the electric flux through the Gaussian surface must also be zero. Gauss’ law then tells us that the net charge enclosed by the Gaussian surface must be zero.

**Reasoning:** With a particle of charge \(-5.0 \, \mu\text{C}\) within the shell, a charge of \(+5.0 \, \mu\text{C}\) must lie on the inner wall of the shell in order that the net enclosed charge be zero. If the particle were centered, this positive charge would be uniformly distributed along the inner wall. However, since the particle is off-center, the distribution of positive charge is skewed, as suggested by Fig. 23-13b, because the positive charge tends to collect on the section of the inner wall nearest the (negative) particle.

Because the shell is electrically neutral, its inner wall can have a charge of \(+5.0 \, \mu\text{C}\) only if electrons, with a total charge of \(-5.0 \, \mu\text{C}\), leave the inner wall and move to the outer wall. There they spread out uniformly, as is also suggested by Fig. 23-13b. This distribution of negative charge is uniform because the shell is spherical and because the skewed distribution of positive charge on the inner wall cannot produce an electric field in the shell to affect the distribution of charge on the outer wall. Furthermore, these negative charges repel one another.

The field lines inside and outside the shell are shown approximately in Fig. 23-13b. All the field lines intersect the shell and the particle perpendicularly. Inside the shell the pattern of field lines is skewed because of the skew of the positive charge distribution. Outside the shell the pattern is the same as if the particle were centered and the shell were missing. In fact, this would be true no matter where inside the shell the particle happened to be located.
Learning Objectives
After reading this module, you should be able to . . .

23.20 Explain how Gauss’ law is used to derive the electric field magnitude outside a line of charge or a cylindrical surface (such as a plastic rod) with a uniform linear charge density \( \lambda \).

23.21 Apply the relationship between linear charge density \( \lambda \) and electric field magnitude on a cylindrical surface and the electric field magnitude \( E \) at radial distance \( r \) from the central axis.

23.22 Explain how Gauss’ law can be used to find the electric field magnitude inside a cylindrical nonconducting surface (such as a plastic rod) with a uniform volume charge density \( \rho \).

Key Idea

The electric field at a point near an infinite line of charge (or charged rod) with uniform linear charge density \( \lambda \) is perpendicular to the line and has magnitude

\[ E = \frac{\lambda}{2\pi\epsilon_0 r} \]  
(line of charge),

where \( r \) is the perpendicular distance from the line to the point.

Applying Gauss’ Law: Cylindrical Symmetry

Figure 23-14 shows a section of an infinitely long cylindrical plastic rod with a uniform charge density \( \lambda \). We want to find an expression for the electric field magnitude \( E \) at radius \( r \) from the central axis of the rod, outside the rod. We could do that using the approach of Chapter 22 (charge element \( dq \), field vector \( \vec{E} \), etc.). However, Gauss’ law gives a much faster and easier (and prettier) approach.

The charge distribution and the field have cylindrical symmetry. To find the field at radius \( r \), we enclose a section of the rod with a concentric Gaussian cylinder of radius \( r \) and height \( h \). (If you want the field at a certain point, put a Gaussian surface through that point.) We can now apply Gauss’ law to relate the charge enclosed by the cylinder and the net flux through the cylinder’s surface.

First note that because of the symmetry, the electric field at any point must be radially outward (the charge is positive). That means that at any point on the end caps, the field only skims the surface and does not pierce it. So, the flux through each end cap is zero.

To find the flux through the cylinder’s curved surface, first note that for any patch element on the surface, the area vector \( d\vec{A} \) is radially outward (away from the interior of the Gaussian surface) and thus in the same direction as the field piercing the patch. The dot product in Gauss’ law is then simply \( E \, dA \cos \theta = E \, dA \), and we can pull \( E \) out of the integral. The remaining integral is just the instruction to sum the areas of all patch elements on the cylinder’s curved surface, but we already know that the total area is the product of the cylinder’s height \( h \) and circumference \( 2\pi r \). The net flux through the cylinder is then

\[ \Phi = E A \cos \theta = E (2\pi rh) \cos 0 = E (2\pi rh). \]

On the other side of Gauss’ law we have the charge \( q_{\text{enc}} \) enclosed by the cylinder. Because the linear charge density (charge per unit length, remember) is uniform, the enclosed charge is \( \lambda h \). Thus, Gauss’ law,

\[ \varepsilon_o \Phi = q_{\text{enc}}, \]

reduces to

\[ \varepsilon_o E (2\pi rh) = \lambda h, \]

yielding

\[ E = \frac{\lambda}{2\pi\epsilon_0 r} \]  
(line of charge).  \hspace{1cm} (23-12)

This is the electric field due to an infinitely long, straight line of charge, at a point that is a radial distance \( r \) from the line. The direction of \( \vec{E} \) is radially outward.
Additional examples, video, and practice available at WileyPLUS

**Sample Problem 23.06  Gauss’ law and an upward streamer in a lightning storm**

*Upward streamer in a lightning storm.* The woman in Fig. 23-15 was standing on a lookout platform high in the Sequoia National Park when a large storm cloud moved overhead. Some of the conduction electrons in her body were driven into the ground by the cloud’s negatively charged base (Fig. 23-16a), leaving her positively charged. You can tell she was highly charged because her hair strands repelled one another and extended away from her along the electric field lines produced by the charge on her.

Lightning did not strike the woman, but she was in extreme danger because that electric field was on the verge of causing electrical breakdown in the surrounding air. Such a breakdown would have occurred along a path extending away from her in what is called an *upward streamer*. An upward streamer is dangerous because the resulting ionization of molecules in the air suddenly frees a tremendous number of electrons from those molecules. Had the woman in Fig. 23-15 developed an upward streamer, the free electrons in the air would have moved to neutralize her (Fig. 23-16b), producing a large, perhaps fatal, charge flow through her body. That charge flow is dangerous because it could have interfered with or even stopped her breathing (which is obviously necessary for oxygen) and the steady beat of her heart (which is obviously necessary for the blood flow that carries the oxygen). The charge flow could also have caused burns.

Let’s model her body as a narrow vertical cylinder of height \( L = 1.8 \text{ m} \) and radius \( R = 0.10 \text{ m} \) (Fig. 23-16c). Assume that charge \( Q \) was uniformly distributed along the cylinder and that electrical breakdown would have occurred if the electric field magnitude along her body had exceeded the critical value \( E_c = 2.4 \text{ MN/C} \). What value of \( Q \) would have put the air along her body on the verge of breakdown?

**KEY IDEA**

Because \( R \ll L \), we can approximate the charge distribution as a long line of charge. Further, because we assume that the charge is uniformly distributed along this line, we can approximate the magnitude of the electric field along the side of her body with Eq. 23-12 (\( E = \lambda/2\pi\varepsilon_0 r \)).

**Calculations:** Substituting the critical value \( E_c \) for \( E \), the cylinder radius \( R \) for radial distance \( r \), and the ratio \( Q/L \) for linear charge density \( \lambda \), we have

\[
E_c = \frac{Q/L}{2\pi\varepsilon_0 R},
\]

or

\[
Q = 2\pi\varepsilon_0 RLE_c.
\]

Substituting given data then gives us

\[
Q = (2\pi)(8.85 \times 10^{-12} \text{ C}^2/\text{N}\cdot\text{m}^2)(0.10 \text{ m}) \\
\times (1.8 \text{ m})(2.4 \times 10^6 \text{ N/C}) \\
= 2.402 \times 10^{-5} \text{ C} \approx 24 \mu\text{C}.
\]

(Answer)

![Figure 23-16](https://example.com/figure23-16.png)

(a) Some of the conduction electrons in the woman’s body are driven into the ground, leaving her positively charged. (b) An upward streamer develops if the air undergoes electrical breakdown, which provides a path for electrons freed from molecules in the air to move to the woman. (c) A cylinder represents the woman.

23-5 APPLYING GAUSS’ LAW: PLANAR SYMMETRY

Learning Objectives

After reading this module, you should be able to . . .

23.23 Apply Gauss’ law to derive the electric field magnitude \( E \) near a large, flat, nonconducting surface with a uniform surface charge density \( \sigma \).

23.24 For points near a large, flat nonconducting surface with a uniform charge density \( \rho \), apply the relationship between the charge density and the electric field magnitude \( E \) and also specify the direction of the field.

23.25 For points near two large, flat, parallel, conducting surfaces with a uniform charge density \( \sigma \), apply the relationship between the charge density and the electric field magnitude \( E \) and also specify the direction of the field.

Key Ideas

- The electric field due to an infinite nonconducting sheet with uniform surface charge density \( \sigma \) is perpendicular to the plane of the sheet and has magnitude
  \[
  E = \frac{\sigma}{2\varepsilon_0} \quad \text{(nonconducting sheet of charge)}.
  \]

- The external electric field just outside the surface of an isolated charged conductor with surface charge density \( \sigma \) is perpendicular to the surface and has magnitude
  \[
  E = \frac{\sigma}{\varepsilon_0} \quad \text{(external, charged conductor)}.
  \]

Inside the conductor, the electric field is zero.

Applying Gauss’ Law: Planar Symmetry

Nonconducting Sheet

Figure 23-17 shows a portion of a thin, infinite, nonconducting sheet with a uniform (positive) surface charge density \( \sigma \). A sheet of thin plastic wrap, uniformly charged on one side, can serve as a simple model. Let us find the electric field \( \vec{E} \) a distance \( r \) in front of the sheet.

A useful Gaussian surface is a closed cylinder with end caps of area \( A \), arranged to pierce the sheet perpendicularly as shown. From symmetry, \( \vec{E} \) must be perpendicular to the sheet and hence to the end caps. Furthermore, since the charge is positive, \( \vec{E} \) is directed away from the sheet, and thus the electric field lines pierce the two Gaussian end caps in an outward direction. Because the field lines do not pierce the curved surface, there is no flux through this portion of the Gaussian surface. Thus \( \vec{E} \cdot d\vec{A} \) is simply \( E \, dA \); then Gauss’ law,

\[
\varepsilon_0 \oint \vec{E} \cdot d\vec{A} = q_{\text{enc}}
\]

becomes

\[
\varepsilon_0 (EA + EA) = \sigma A,
\]

where \( \sigma A \) is the charge enclosed by the Gaussian surface. This gives

\[
E = \frac{\sigma}{2\varepsilon_0} \quad \text{(sheet of charge)}.
\]

((23-13)

Since we are considering an infinite sheet with uniform charge density, this result holds for any point at a finite distance from the sheet. Equation 23-13 agrees with Eq. 22-27, which we found by integration of electric field components.

Figure 23-17 (a) Perspective view and (b) side view of a portion of a very large, thin plastic sheet, uniformly charged on one side to surface charge density \( \sigma \). A closed cylindrical Gaussian surface passes through the sheet and is perpendicular to it.

There is flux only through the two end faces.
Two Conducting Plates

Figure 23-18a shows a cross section of a thin, infinite conducting plate with excess positive charge. From Module 23-3 we know that this excess charge lies on the surface of the plate. Since the plate is thin and very large, we can assume that essentially all the excess charge is on the two large faces of the plate.

If there is no external electric field to force the positive charge into some particular distribution, it will spread out on the two faces with a uniform surface charge density of magnitude \( \sigma \). From Eq. 23-11 we know that just outside the plate this charge sets up an electric field of magnitude \( E = \sigma / \varepsilon_0 \). Because the excess charge is positive, the field is directed away from the plate.

Figure 23-18b shows an identical plate with excess negative charge having the same magnitude of surface charge density \( \sigma \). The only difference is that now the electric field is directed toward the plate.

Suppose we arrange for the plates of Figs. 23-18a and b to be close to each other and parallel (Fig. 23-18c). Since the plates are conductors, when we bring them into this arrangement, the excess charge on one plate attracts the excess charge on the other plate, and all the excess charge moves onto the inner faces of the plates as in Fig. 23-18c. With twice as much charge now on each inner face, the new surface charge density (call it \( \sigma \)) on each inner face is twice \( \sigma \). Thus, the electric field at any point between the plates has the magnitude

\[
E = \frac{2\sigma}{\varepsilon_0} = \frac{\sigma}{\varepsilon_0}. \tag{23-14}
\]

This field is directed away from the positively charged plate and toward the negatively charged plate. Since no excess charge is left on the outer faces, the electric field to the left and right of the plates is zero.

Because the charges moved when we brought the plates close to each other, the charge distribution of the two-plate system is not merely the sum of the charge distributions of the individual plates.

One reason why we discuss seemingly unrealistic situations, such as the field set up by an infinite sheet of charge, is that analyses for “infinite” situations yield good approximations to many real-world problems. Thus, Eq. 23-13 holds well for a finite nonconducting sheet as long as we are dealing with points close to the sheet and not too near its edges. Equation 23-14 holds well for a pair of finite conducting plates as long as we consider points that are not too close to their edges. The trouble with the edges is that near an edge we can no longer use planar symmetry to find expressions for the fields. In fact, the field lines there are curved (said to be an edge effect or fringing), and the fields can be very difficult to express algebraically.

Sample Problem 23.07 Electric field near two parallel nonconducting sheets with charge

Figure 23-19a shows portions of two large, parallel, nonconducting sheets, each with a fixed uniform charge on one side. The magnitudes of the surface charge densities are \( \sigma_1(+) = 6.8 \, \mu C/m^2 \) for the positively charged sheet and \( \sigma_1(-) = 4.3 \, \mu C/m^2 \) for the negatively charged sheet.

Find the electric field \( \vec{E} \) (a) to the left of the sheets, (b) between the sheets, and (c) to the right of the sheets.

KEY IDEA

With the charges fixed in place (they are on nonconductors), we can find the electric field of the sheets in Fig. 23-19a by (1) finding the field of each sheet as if that sheet were isolated and (2) algebraically adding the fields of the isolated sheets.
via the superposition principle. (We can add the fields algebraically because they are parallel to each other.)

Calculations: At any point, the electric field \( \vec{E}_{(+)} \) due to the positive sheet is directed away from the sheet and, from Eq. 23-13, has the magnitude

\[
E_{(+)} = \frac{\sigma_{(+)}}{2\varepsilon_0} = \frac{6.8 \times 10^{-6} \text{C/m}^2}{(2)(8.85 \times 10^{-12} \text{C}^2/\text{N} \cdot \text{m}^2)} = 3.84 \times 10^5 \text{N/C.}
\]

Similarly, at any point, the electric field \( \vec{E}_{(-)} \) due to the negative sheet is directed toward that sheet and has the magnitude

\[
E_{(-)} = \frac{\sigma_{(-)}}{2\varepsilon_0} = \frac{4.3 \times 10^{-6} \text{C/m}^2}{(2)(8.85 \times 10^{-12} \text{C}^2/\text{N} \cdot \text{m}^2)} = 2.43 \times 10^5 \text{N/C.}
\]

Figure 23-19b shows the fields set up by the sheets to the left of the sheets \( (L) \), between them \( (B) \), and to their right \( (R) \).

The resultant fields in these three regions follow from the superposition principle. To the left, the field magnitude is

\[
E_L = E_{(+)} - E_{(-)} = 3.84 \times 10^5 \text{N/C} - 2.43 \times 10^5 \text{N/C} = 1.4 \times 10^5 \text{N/C.} \quad \text{(Answer)}
\]

Because \( E_{(+)} \) is larger than \( E_{(-)} \), the net electric field \( \vec{E}_L \) in this region is directed to the left, as Fig. 23-19c shows. To the right of the sheets, the net electric field has the same magnitude but is directed to the right, as Fig. 23-19c shows.

Between the sheets, the two fields add and we have

\[
E_B = E_{(+)} + E_{(-)} = 3.84 \times 10^5 \text{N/C} + 2.43 \times 10^5 \text{N/C} = 6.3 \times 10^5 \text{N/C.} \quad \text{(Answer)}
\]

The electric field \( \vec{E}_B \) is directed to the right.
Figure 23-20 A thin, uniformly charged, spherical shell with total charge $q$, in cross section. Two Gaussian surfaces $S_1$ and $S_2$ are also shown in cross section. Surface $S_2$ encloses the shell, and $S_1$ encloses only the empty interior of the shell.

Figure 23-21 The dots represent a spherically symmetric distribution of charge of radius $R$, whose volume charge density $\rho$ is a function only of distance from the center. The charged object is not a conductor, and therefore the charge is assumed to be fixed in position. A concentric spherical Gaussian surface with $r > R$ is shown in (a). A similar Gaussian surface with $r < R$ is shown in (b).

Figure 23-20 shows a charged spherical shell of total charge $q$ and radius $R$ and two concentric spherical Gaussian surfaces, $S_1$ and $S_2$. If we followed the procedure of Module 23-2 as we applied Gauss’ law to surface $S_2$, for which $r \geq R$, we would find that

$$E = \frac{1}{4\pi\epsilon_0} \frac{q}{r^2} \quad \text{(spherical shell, field at } r \geq R). \quad (23-15)$$

This field is the same as one set up by a particle with charge $q$ at the center of the shell of charge. Thus, the force produced by a shell of charge $q$ on a charged particle placed outside the shell is the same as if all the shell’s charge is concentrated as a particle at the shell’s center. This proves the first shell theorem.

Applying Gauss’ law to surface $S_1$, for which $r < R$, leads directly to

$$E = 0 \quad \text{(spherical shell, field at } r < R), \quad (23-16)$$

because this Gaussian surface encloses no charge. Thus, if a charged particle were enclosed by the shell, the shell would exert no net electrostatic force on the particle. This proves the second shell theorem.

If a charged particle is located inside a shell of uniform charge, there is no electrostatic force on the particle from the shell.

Any spherically symmetric charge distribution, such as that of Fig. 23-21, can be constructed with a nest of concentric spherical shells. For purposes of applying the two shell theorems, the volume charge density $\rho$ should have a single value for each shell but need not be the same from shell to shell. Thus, for the charge distribution as a whole, $\rho$ can vary, but only with $r$, the radial distance from the center. We can then examine the effect of the charge distribution “shell by shell.”

In Fig. 23-21a, the entire charge lies within a Gaussian surface with $r > R$. The charge produces an electric field on the Gaussian surface as if the charge were that of a particle located at the center, and Eq. 23-15 holds.

Figure 23-21b shows a Gaussian surface with $r < R$. To find the electric field at points on this Gaussian surface, we separately consider the charge inside it and the charge outside it. From Eq. 23-16, the outside charge does not set up a field on the Gaussian surface. From Eq. 23-15, the inside charge sets up a field as though it is concentrated at the center. Letting $q'$ represent that enclosed charge, we can then rewrite Eq. 23-15 as

$$E = \frac{1}{4\pi\epsilon_0} \frac{q'}{r^2} \quad \text{(spherical distribution, field at } r \leq R). \quad (23-17)$$

*If the full charge $q$ enclosed within radius $R$ is uniform, then $q'$ enclosed within radius $r$ in Fig. 23-21b is proportional to $q$:

$$\frac{\text{charge enclosed by}}{\text{volume enclosed by}} = \frac{\text{full charge}}{\text{full volume}}$$

or

$$\frac{q'}{\frac{4}{3}\pi r^3} = \frac{q}{\frac{4}{3}\pi R^3}. \quad (23-18)$$

This gives us

$$q' = q \frac{r^3}{R^3}. \quad (23-19)$$

Substituting this into Eq. 23-17 yields

$$E = \left(\frac{q}{4\pi\epsilon_0 R^3}\right) r \quad \text{(uniform charge, field at } r \leq R). \quad (23-20)$$
Checkpint 4

The figure shows two large, parallel, nonconducting sheets with identical (positive) uniform surface charge densities, and a sphere with a uniform (positive) volume charge density. Rank the four numbered points according to the magnitude of the net electric field there, greatest first.

Review & Summary

Gauss’ Law

Gauss’ law and Coulomb’s law are different ways of describing the relation between charge and electric field in static situations. Gauss’ law is

$$\varepsilon_0 \Phi = q_{enc} \quad \text{(Gauss’ law),} \quad (23-6)$$

in which \(q_{enc}\) is the net charge inside an imaginary closed surface (a Gaussian surface) and \(\Phi\) is the net flux of the electric field through the surface:

$$\Phi = \int \vec{E} \cdot d\vec{A} \quad \text{(electric flux through a Gaussian surface).} \quad (23-4)$$

Coulomb’s law can be derived from Gauss’ law.

Applications of Gauss’ Law

Using Gauss’ law and, in some cases, symmetry arguments, we can derive several important results in electrostatic situations. Among these are:

1. An excess charge on an isolated conductor is located entirely on the outer surface of the conductor.

2. The external electric field near the surface of a charged conductor is perpendicular to the surface and has a magnitude that depends on the surface charge density \(\sigma\):

$$E = \frac{\sigma}{\varepsilon_0} \quad \text{(conducting surface).} \quad (23-11)$$

Within the conductor, \(E = 0\).

3. The electric field at any point due to an infinite line of charge with uniform linear charge density \(\lambda\) is perpendicular to the line of charge and has magnitude

$$E = \frac{\lambda}{2\pi r} \quad \text{(line of charge),} \quad (23-12)$$

where \(r\) is the perpendicular distance from the line of charge to the point.

4. The electric field due to an infinite nonconducting sheet with uniform surface charge density \(\sigma\) is perpendicular to the plane of the sheet and has magnitude

$$E = \frac{\sigma}{2\varepsilon_0} \quad \text{(sheet of charge).} \quad (23-13)$$

5. The electric field outside a spherical shell of charge with radius \(R\) and total charge \(q\) is directed radially and has magnitude

$$E = \frac{1}{4\pi\varepsilon_0} \frac{q}{r^2} \quad \text{(spherical shell, for } r \geq R). \quad (23-15)$$

Here \(r\) is the distance from the center of the shell to the point at which \(E\) is measured. (The charge behaves, for external points, as if it were all located at the center of the sphere.) The field inside a uniform spherical shell of charge is exactly zero:

$$E = 0 \quad \text{(spherical shell, for } r < R). \quad (23-16)$$

6. The electric field inside a uniform sphere of charge is directed radially and has magnitude

$$E = \left(\frac{q}{4\pi\varepsilon_0 R^3}\right) r. \quad (23-20)$$

Questions

1. A surface has the area vector \(\vec{A} = (2\hat{i} + 3\hat{j}) \text{ m}^2\). What is the flux of a uniform electric field through the area if the field is (a) \(\vec{E} = 4\hat{i} \text{ N/C}\) and (b) \(\vec{E} = 4\hat{k} \text{ N/C}\)?

2. Figure 23-22 shows, in cross section, three solid cylinders, each of length \(L\) and uniform charge \(Q\). Concentric with each cylinder is a cylindrical Gaussian surface, with all three surfaces having the same radius. Rank the Gaussian surfaces according to the electric field at any point on the surface, greatest first.

3. Figure 23-23 shows, in cross section, a central metal ball, two spherical metal shells, and three spherical Gaussian surfaces of radii \(R, 2R,\) and \(3R\), all with the same center. The uniform charges on the three objects are: ball, \(Q\); smaller shell, \(3Q\); larger shell, \(5Q\). Rank the Gaussian surfaces according to the magnitude of the electric field at any point on the surface, greatest first.

![Figure 23-22 Question 2.](image)

![Figure 23-23 Question 3.](image)
4. Figure 23-24 shows, in cross section, two Gaussian spheres and two Gaussian cubes that are centered on a positively charged particle. (a) Rank the net flux through the four Gaussian surfaces, greatest first. (b) Rank the magnitudes of the electric fields on the surfaces, greatest first, and indicate whether the magnitudes are uniform or variable along each surface.

5. In Fig. 23-25, an electron is released between two infinite nonconducting sheets that are horizontal and have uniform surface charge densities \( \sigma_{(+)} \) and \( \sigma_{(-)} \), as indicated. The electron is subjected to the following three situations involving surface charge densities and sheet separations. Rank the magnitudes of the electron’s acceleration, greatest first.

6. Three infinite nonconducting sheets, with uniform positive surface charge densities \( \sigma, 2\sigma, \) and \( 3\sigma \), are arranged to be parallel like the two sheets in Fig. 23-19a. What is their order, from left to right, if the electric field \( \mathbf{E} \) produced by the arrangement has magnitude \( \mathbf{E} = 0 \) in one region and \( \mathbf{E} = 2\sigma \varepsilon_0 \) in another region?

7. Figure 23-26 shows four situations in which four very long rods extend into and out of the page (we see only their cross sections). The value below each cross section gives that particular rod’s uniform charge density in microcoulombs per meter. The rods are separated by either \( d \) or \( 2d \) as drawn, and a central point is shown midway between the inner rods. Rank the situations according to the magnitude of the net electric field at that central point, greatest first.

8. Figure 23-27 shows four solid spheres, each with charge \( Q \) uniformly distributed through its volume. (a) Rank the spheres according to their volume charge density, greatest first. The figure also shows a point \( P \) for each sphere, all at the same distance from the center of the sphere. (b) Rank the spheres according to the magnitude of the electric field they produce at point \( P \), greatest first.

9. A small charged ball lies within the hollow of a metallic spherical shell of radius \( R \). For three situations, the net charges on the ball and shell, respectively, are (1) \(+4q, 0\); (2) \(-6q, 10q\); (3) \(+16q, -12q\). Rank the situations according to the charge on (a) the inner surface of the shell and (b) the outer surface, most positive first.

10. Rank the situations of Question 9 according to the magnitude of the electric field (a) halfway through the shell and (b) at a point \( 2R \) from the center of the shell, greatest first.

11. Figure 23-28 shows a section of three long charged cylinders centered on the same axis. Central cylinder \( A \) has a uniform charge \( q_A = +3q_0 \). What uniform charges \( q_B \) and \( q_C \) should be on cylinders \( B \) and \( C \) so that (if possible) the net electric field is zero at (a) point 1, (b) point 2, and (c) point 3?

12. Figure 23-29 shows four Gaussian surfaces consisting of identical cylindrical midsections but different end caps. The surfaces are in a uniform electric field \( \mathbf{E} \) that is directed parallel to the central axis of each cylindrical midsection. The end caps have these shapes: \( S_1 \), convex hemispheres; \( S_2 \), concave hemispheres; \( S_3 \), cones; \( S_4 \), flat disks. Rank the surfaces according to (a) the net electric flux through them and (b) the electric flux through the top end caps, greatest first.
Module 23-1 Electric Flux

1. The square surface shown in Fig. 23-30 measures 3.2 mm on each side. It is immersed in a uniform electric field with magnitude $E = 1800 \text{ N/C}$ and with field lines at an angle of $\theta = 35^\circ$ with a normal to the surface, as shown. Take that normal to be directed “outward,” as though the surface were one face of a box. Calculate the electric flux through the surface.

2. An electric field given by $E = 4.0\hat{i} - 3.0(y^2 + 2.0)\hat{j}$ pierces a Gaussian cube of edge length 2.0 m and positioned as shown in Fig. 23-7. What is the electric flux through the (a) top face, (b) bottom face, (c) left face, and (d) back face? (e) What is the net electric flux through the cube?

3. The cube in Fig. 23-31 has edge length 1.40 m and is oriented as shown in a region of uniform electric field. Find the electric flux through the right face if the electric field, in newtons per coulomb, is given by (a) $6.00\hat{i}$, (b) $-2.00\hat{j}$, and (c) $-3.00\hat{i} + 4.00\hat{k}$. (d) What is the total flux through the cube for each field?

Module 23-2 Gauss’ Law

4. In Fig. 23-32, a butterfly net is in a uniform electric field of magnitude $E = 3.0 \text{ mN/C}$. The rim, a circle of radius $a = 11 \text{ cm}$, is aligned perpendicular to the field. The net contains no net charge. Find the electric flux through the netting.

5. In Fig. 23-33, a proton is a distance $d/2$ directly above the center of a square of side $d$. What is the magnitude of the electric flux through the square? (Hint: Think of the square as one face of a cube with edge $d$.)

6. At each point on the surface of the cube shown in Fig. 23-31, the electric field is parallel to the $z$ axis. The length of each edge of the cube is 3.0 m. On the top face of the cube the field is $\vec{E} = -34\hat{k} \text{ N/C}$, and on the bottom face it is $\vec{E} = +20\hat{k} \text{ N/C}$. Determine the net charge contained within the cube.

7. A particle of charge 1.8 $\mu\text{C}$ is at the center of a Gaussian cube 55 cm on edge. What is the net electric flux through the surface?

8. When a shower is turned on in a closed bathroom, the splashing of the water on the bare tub can fill the room’s air with negatively charged ions and produce an electric field in the air as great as 1000 $\text{N/C}$. Consider a bathroom with dimensions 2.5 m $\times$ 3.0 m $\times$ 2.0 m. Along the ceiling, floor, and four walls, approximate the electric field in the air as being directed perpendicular to the surface and as having a uniform magnitude of 600 $\text{N/C}$. Also, treat those surfaces as forming a closed Gaussian surface around the room’s air. What are (a) the volume charge density $\rho$ and (b) the number of excess elementary charges $e$ per cubic meter in the room’s air?

9. Fig. 23-31 shows a Gaussian surface in the shape of a cube with edge length 1.40 m. What are (a) the net flux $\Phi$ through the surface and (b) the net charge $q_{\text{enc}}$ enclosed by the surface if $\vec{E} = (3.00y) \text{ N/C}$, with $y$ in meters? What are (c) $\Phi$ and (d) $q_{\text{enc}}$ if $\vec{E} = \left[-4.00\hat{i} + (6.00 + 3.00y)\hat{j}\right] \text{ N/C}$?

10. Figure 23-34 shows a closed Gaussian surface in the shape of a cube of edge length 2.00 m. It lies in a region where the nonuniform electric field is given by $\vec{E} = (3.00x + 4.00)\hat{i} + 6.00\hat{j} + 7.00k \text{ N/C}$, with $x$ in meters. What is the net charge contained by the cube?

11. Fig. 23-35 shows a closed Gaussian surface in the shape of a cube of edge length 2.00 m, with one corner at $x_1 = 5.00 \text{ m}, y_1 = 4.00 \text{ m}$. The cube lies in a region where the electric field vector is given by $\vec{E} = -3.00\hat{i} - 4.00\hat{j} + 3.00k \text{ N/C}$, with $y$ in meters. What is the net charge contained by the cube?

12. Figure 23-36 shows two nonconducting spherical shells fixed in place. Shell 1 has uniform surface charge density $+6.0 \mu\text{C/m}^2$ on its outer surface and radius 3.0 cm; shell 2 has uniform surface charge density $+4.0 \mu\text{C/m}^2$ on its outer surface and radius 2.0 cm; the shell centers are separated by $L = 10 \text{ cm}$. In unit-vector notation, what is the net electric field at $x = 2.0 \text{ cm}$?
The electric field in a certain region of Earth’s atmosphere is directed vertically down. At an altitude of 300 m the field has magnitude 60.0 N/C; at an altitude of 200 m, the magnitude is 100 N/C. Find the net amount of charge contained in a cube 100 m on edge, with horizontal faces at altitudes of 200 and 300 m.

Flux and nonconducting shells. A charged particle is suspended at the center of two concentric spherical shells that are very thin and made of nonconducting material. Figure 23-37 gives the net flux $\Phi$ through a Gaussian sphere centered on the particle, as a function of the radius $r$ of the sphere. The scale of the vertical axis is set by $\Phi = 5.0 \times 10^5 \, \text{N} \cdot \text{m}^2/\text{C}$. (a) What is the charge of the central particle? What are the net charges of (b) shell $A$ and (c) shell $B$?

An isolated conductor has net charge $+10 \times 10^{-6} \, \text{C}$ and a cavity with a particle of charge $-3.0 \times 10^{-8} \, \text{C}$. What is the charge on (a) the cavity wall and (b) the outer surface?

Module 23-4 Applying Gauss’ Law: Cylindrical Symmetry

An electron is released 9.0 cm from a very long nonconducting rod with a uniform 6.0 $\mu\text{C}/\text{m}$. What is the magnitude of the electron’s initial acceleration?

The drum of a photocopying machine has a length of 42 cm and a diameter of 12 cm. The electric field just above the drum’s surface is $2.3 \times 10^5 \, \text{N} / \text{C}$. What is the total charge on the drum? (b) The manufacturer wishes to produce a desktop version of the machine. This requires reducing the drum length to 28 cm and the diameter to 8.0 cm. The electric field at the drum surface must not change. What must be the charge on this new drum?

An infinite line of charge produces a field of magnitude $4.5 \times 10^4 \, \text{N} / \text{C}$ at distance 2.0 m. Find the linear charge density.

Figure 23-40 Problem 24.

Module 23-3 A Charged Isolated Conductor

A uniformly charged conducting sphere of 1.2 m diameter has surface charge density $8.1 \, \mu\text{C}/\text{m}^2$. Find (a) the net charge on the sphere and (b) the total electric flux leaving the surface.

The electric field just above the surface of the charged conducting drum of a photocopying machine has a magnitude $E$ of $2.3 \times 10^5 \, \text{N} / \text{C}$. What is the surface charge density on the drum?

Space vehicles traveling through Earth’s radiation belts can intercept a significant number of electrons. The resulting charge buildup can damage electronic components and disrupt operations. Suppose a spherical metal satellite 1.3 m in diameter accumulates $2.4 \, \mu\text{C}$ of charge in one orbital revolution. (a) Find the resulting surface charge density. (b) Calculate the magnitude of the electric field just outside the surface of the satellite, due to the surface charge.

Figure 23-41 Problem 26.

Figure 23-37 Problem 14.

Figure 23-38 Problem 16.
ducting and thin and have uniform surface charge densities on their outer surfaces. Figure 23-41b gives the radial component \( E \) of the electric field versus radial distance \( r \) from the common axis, and \( E_r = 3.0 \times 10^3 \text{ N/C} \). What is the shell’s linear charge density?

\*27 \** A long, straight wire has fixed negative charge with a linear charge density of magnitude 3.6 nC/m. The wire is to be enclosed by a coaxial, thin-walled nonconducting cylindrical shell of radius 1.5 cm. The shell is to have positive charge on its outside surface with a surface charge density \( \sigma \) that makes the net external electric field zero. Calculate \( \sigma \).

\*28 \** A charge of uniform linear density 2.0 nC/m is distributed along a long, thin, nonconducting rod. The rod is coaxial with a long conducting cylindrical shell (inner radius = 5.0 cm, outer radius = 10 cm). The net charge on the shell is zero. (a) What is the magnitude of the electric field 15 cm from the axis of the shell? What is the surface charge density on the (b) inner and (c) outer surface of the shell?

\*29 SSM WWW Figure 23-42 is a section of a conducting rod of radius \( R_1 = 1.30 \text{ mm} \) and length \( L = 11.0 \text{ m} \) inside a thin-walled coaxial conducting cylindrical shell of radius \( R_2 = 10.0 R_1 \) and the (same) length \( L \). The net charge on the rod is \( Q_1 = +3.40 \times 10^{-12} \text{ C} \); that on the shell is \( Q_2 = -2.00 Q_1 \). What are the (a) magnitude \( E \) and (b) direction (radially inward or outward) of the electric field at radial distance \( r = 2.00 R_2 \)? What are (c) \( E \) and (d) the direction at \( r = 5.00 R_1 \)? What is the charge on the (e) interior and (f) exterior surface of the shell?

\*30 In Fig. 23-43, short sections of two very long parallel lines of charge are shown, fixed in place, separated by \( L = 8.0 \text{ cm} \). The uniform linear charge densities are \( +6.0 \mu \text{C/m} \) for line 1 and \( -2.0 \mu \text{C/m} \) for line 2. Where along the \( x \) axis shown is the net electric field from the two lines zero?

\*31 ILW Two long, charged, thin-walled, concentric cylindrical shells have radii of 3.0 and 6.0 cm. The charge per unit length is \( 5.0 \times 10^{-6} \text{ C/m} \) on the inner shell and \( -7.0 \times 10^{-6} \text{ C/m} \) on the outer shell. What are the (a) magnitude \( E \) and (b) direction (radially inward or outward) of the electric field at radial distance \( r = 4.0 \text{ cm} \)? What are (c) \( E \) and (d) the direction at \( r = 8.0 \text{ cm} \)?

\*32 A long, nonconducting, solid cylinder of radius 4.0 cm has a nonuniform volume charge density \( \rho \) that is a function of radial distance \( r \) from the cylinder axis: \( \rho = Ar^2 \). For \( A = 2.5 \mu \text{C/m}^3 \), what is the magnitude of the electric field at (a) \( r = 3.0 \text{ cm} \) and (b) \( r = 5.0 \text{ cm} \)?

**Module 23-5 Applying Gauss’ Law: Planar Symmetry**

\*33 In Fig. 23-44, two large, thin metal plates are parallel and close to each other. On their inner faces, the plates have excess surface charge densities of opposite signs and magnitude \( 7.00 \times 10^{-22} \text{ C/m}^2 \). In unit-vector notation, what is the electric field at points (a) to the left of the plates, (b) to the right of them, and (c) between them?

\*34 In Fig. 23-45, a small circular hole of radius \( R = 1.80 \text{ cm} \) has been cut in the middle of an infinite, flat, nonconducting surface that has uniform charge density \( \sigma = 4.50 \text{ pC/m}^2 \). A \( z \) axis, with its origin at the hole’s center, is perpendicular to the surface. In unit-vector notation, what is the electric field at point \( P \) at \( z = 2.56 \text{ cm} \)? (Hint: See Eq. 22-26 and use superposition.)

\*35 Figure 23-46a shows three plastic sheets that are large, parallel, and uniformly charged. Figure 23-46b gives the component of the net electric field along an \( x \) axis through the sheets. The scale of the vertical axis is set by \( E_x = 6.0 \times 10^2 \text{ N/C} \). What is the ratio of the charge density on sheet 3 to that on sheet 2?

\*36 Figure 23-47 shows cross sections through two large, parallel, nonconducting sheets with identical distributions of positive charge with surface charge density \( \sigma = 1.77 \times 10^{-22} \text{ C/m}^2 \). In unit-vector notation, what is \( \vec{E} \) at points (a) above the sheets, (b) between them, and (c) below them?

\*37 SSM WWW A square metal plate of edge length 8.0 cm and negligible thickness has a total charge of \( 6.0 \times 10^{-6} \text{ C} \). (a) Estimate the magnitude \( E \) of the electric field just off the center of the plate (at, say, a distance of 0.50 mm from the center) by assuming that the charge is spread uniformly over the two faces of the plate. (b) Estimate \( E \) at a distance of 30 m (large relative to the plate size) by assuming that the plate is a charged particle.
In Fig. 23-48a, an electron is shot directly away from a uniformly charged plastic sheet, at speed $v_0 = 2.0 \times 10^3$ m/s. The sheet is nonconducting, flat, and very large. Figure 23-48b gives the electron’s vertical velocity component $v$ versus time $t$ until the return to the launch point. What is the sheet’s surface charge density?

Figure 23-48 Problem 38.

In Fig. 23-49, a small, nonconducting ball of mass $m = 1.0 \text{mg}$ and charge $q = 2.0 \times 10^{-8}$ C (distributed uniformly through its volume) hangs from an insulating thread that makes an angle $\theta = 30^\circ$ with a vertical, uniformly charged nonconducting sheet (shown in cross section). Considering the gravitational force on the ball and assuming the sheet extends far vertically and into and out of the page, calculate the surface charge density $\sigma$ of the sheet.

Figure 23-49 Problem 39.

Figure 23-50 shows a very large nonconducting sheet that has a uniform surface charge density of $\sigma = -2.00 \mu \text{C/m}^2$; it also shows a particle of charge $Q = 6.00 \mu \text{C}$, at distance $d$ from the sheet. Both are fixed in place. If $d = 0.200$ m, at what (a) positive and (b) negative coordinate on the $x$ axis (other than infinity) is the net electric field $E_{\text{net}}$ of the sheet and particle zero? (c) If $d = 0.800$ m, at what coordinate on the $x$ axis is $E_{\text{net}} = 0$?

Figure 23-50 Problem 40.

An electron is shot directly toward the center of a large metal plate that has surface charge density $-2.0 \times 10^{-6}$ C/m$^2$. If the initial kinetic energy of the electron is $1.60 \times 10^{-17}$ J and if the electron is to stop (due to electrostatic repulsion from the plate) just as it reaches the plate, how far from the plate must the launch point be?

Figure 23-51 Problem 41.

Two large metal plates of area $1.0 \text{m}^2$ face each other, 5.0 cm apart, with equal charge magnitudes $|q|$ but opposite signs. The field magnitude $E$ between them (neglect fringing) is 55 N/C. Find $|q|$.

Figure 23-52 Problem 42.

In Fig. 23-53, a solid sphere of radius $a = 2.00$ cm is concentric with a spherical conducting shell of inner radius $b = 2.00a$ and outer radius $c = 2.40a$. The sphere has a net uniform charge $q_s = +5.00 \mu \text{C}$; the shell has a net charge $q_f = -q_s$. What is the magnitude of the electric field at radial distances (a) $r = 0$, (b) $r = a/2.00$, (c) $r = a$, (d) $r = 1.50a$, (e) $r = 2.30a$, and (f) $r = 3.50a$? What is the net charge on the (g) inner and (h) outer surface of the shell?

Figure 23-53 Problem 43.

Figure 23-54 Problem 44.

Figure 23-55 Problem 45.

Figure 23-56 Problem 46.

Figure 23-57 Problem 47.

Figure 23-58 Problem 48.

Figure 23-59 Problem 49.
Figure 23-55 shows two nonconducting spherical shells fixed in place on an x axis. Shell 1 has uniform surface charge density $+4.0 \, \mu C/m^2$ on its outer surface and radius 0.50 cm, and shell 2 has uniform surface charge density $-2.0 \, \mu C/m^2$ on its outer surface and radius 2.0 cm; the centers are separated by $L = 6.0$ cm. Other than at $x = \infty$, where on the x axis is the net electric field equal to zero?

Figure 23-56, a nonconducting spherical shell of inner radius $a = 2.00$ cm and outer radius $b = 2.40$ cm has (within its thickness) a positive volume charge density $\rho = A/r$, where $A$ is a constant and $r$ is the distance from the center of the shell. In addition, a small ball of density (mass) a positive volume charge $q$ is at the location of the coordinate $x = 4.0 \, \text{cm}$ and $y = 6.0 \, \text{cm}$.

Figure 23-57 shows a spherical shell with uniform volume charge density $\rho = 1.84 \, \text{nC/m}^3$, inner radius $a = 10.0$ cm, and outer radius $b = 2.00a$. What is the magnitude of the electric field at radial distances (a) $r = 0$, (b) $r = a/2.00$, (c) $r = a$, (d) $r = 1.50a$, (e) $r = b$, and (f) $r = 3.00b$?

Figure 23-58 shows, in cross section, two solid spheres with uniformly distributed charge throughout their volumes. Each has radius $R$. Point $P$ lies on a line connecting the centers of the spheres, at radial distance $R/2.00$ from the center of sphere 1. If the net electric field at point $P$ is zero, what is the ratio of $q_2/q_1$ of the total charges?

A charge distribution that is spherically symmetric but not uniform radially produces an electric field of magnitude $E = Kr^4$, directed radially outward from the center of the sphere. Here $r$ is the radial distance from that center, and $K$ is a constant. What is the volume density $\rho$ of the charge distribution?

**Additional Problems**

The electric field in a particular space is $\vec{E} = (x + 2)\hat{\jmath}$ N/C, with $x$ in meters. Consider a cylindrical Gaussian surface of radius 20 cm that is coaxial with the $x$ axis. One end of the cylinder is at $x = 0$. (a) What is the magnitude of the electric flux through the other end of the cylinder at $x = 2.0 \, \text{m}$? (b) What net charge is enclosed within the cylinder?
doubled, how much flux would pass through the surface? (b) What is the charge of the particle?

67 SSM The electric field at point $P$ just outside the outer surface of a hollow spherical conductor of inner radius 10 cm and outer radius 20 cm has magnitude 450 N/C and is directed outward. When a particle of unknown charge $Q$ is introduced into the center of the sphere, the electric field at $P$ is still directed outward but is now 180 N/C. (a) What was the net charge enclosed by the outer surface before $Q$ was introduced? (b) What is charge $Q$? After $Q$ is introduced, what is the charge on the (c) inner and (d) outer surface of the conductor?

68 The net electric flux through each face of a die (singular of dice) has a magnitude in units of $10^4$ N·m²/C that is exactly equal to the number of spots $N$ on the face (1 through 6). The flux is inward for $N$ odd and outward for $N$ even. What is the net charge inside the die?

69 Figure 23-59 shows, in cross section, three infinitely large nonconducting sheets on which charge is uniformly spread. The surface charge densities are $\sigma_1 = +2.00 \mu\text{C/m}^2$, $\sigma_2 = +4.00 \mu\text{C/m}^2$, and $\sigma_3 = -5.00 \mu\text{C/m}^2$, and distance $L = 1.50$ cm. In unit-vector notation, what is the net electric field at point $P$?

70 Charge of uniform volume density $\rho = 3.2 \mu\text{C/m}^3$ fills a nonconducting solid sphere of radius 5.0 cm. What is the magnitude of the electric field (a) 3.5 cm and (b) 8.0 cm from the sphere’s center?

71 A Gaussian surface in the form of a hemisphere of radius $R = 5.68$ cm lies in a uniform electric field of magnitude $E = 2.50$ N/C. The surface encloses no net charge. At the (flat) base of the surface, the field is perpendicular to the surface and directed into the surface. What is the flux through (a) the base and (b) the curved portion of the surface?

72 What net charge is enclosed by the Gaussian cube of Problem 2?

73 A nonconducting solid sphere has a uniform volume charge density $\rho$. Let $\vec{r}$ be the vector from the center of the sphere to a general point $P$ within the sphere. (a) Show that the electric field at $P$ is given by $\vec{E} = \rho\vec{r}/3\epsilon_0$. (Note that the result is independent of the radius of the sphere.) (b) A spherical cavity is hollowed out of the sphere, as shown in Fig. 23-60. Using superposition concepts, show that the electric field at all points within the cavity is uniform and equal to $\vec{E} = \rho\vec{a}/3\epsilon_0$, where $\vec{a}$ is the position vector from the center of the sphere to the center of the cavity.

74 A uniform charge density of 500 nC/m³ is distributed throughout a spherical volume of radius 6.00 cm. Consider a cubical Gaussian surface with its center at the center of the sphere. What is the electric flux through this cubical surface if its edge length is (a) 4.00 cm and (b) 14.0 cm?

75 Figure 23-61 shows a Geiger counter, a device used to detect ionizing radiation, which causes ionization of atoms. A thin, positively charged central wire is surrounded by a concentric, circular, conducting cylindrical shell with an equal negative charge, creating a strong radial electric field. The shell contains a low-pressure inert gas. A particle of radiation entering the device through the shell wall ionizes a few of the gas atoms. The resulting free electrons (e) are drawn to the positive wire. However, the electric field is so intense that, between collisions with gas atoms, the free electrons gain energy sufficient to ionize these atoms also. More free electrons are thereby created, and the process is repeated until the electrons reach the wire. The resulting “avalanche” of electrons is collected by the wire, generating a signal that is used to record the passage of the original particle of radiation. Suppose that the radius of the central wire is 25 μm, the inner radius of the shell 1.4 cm, and the length of the shell 16 cm. If the electric field at the shell’s inner wall is 2.9 × 10⁴ N/C, what is the total positive charge on the central wire?

76 Charge is distributed uniformly throughout the volume of an infinitely long solid cylinder of radius $R$. (a) Show that, at a distance $r < R$ from the cylinder axis, $E = \frac{\rho r}{2\epsilon_0}$, where $\rho$ is the volume charge density. (b) Write an expression for $E$ when $r > R$.

77 SSM A spherical conducting shell has a charge of $-14 \mu\text{C}$ on its outer surface and a charged particle in its hollow. If the net charge on the shell is $-10 \mu\text{C}$, what is the charge (a) on the inner surface of the shell and (b) of the particle?

78 A charge of 6.00 pC is spread uniformly throughout the volume of a sphere of radius $r = 4.00$ cm. What is the magnitude of the electric field at a radial distance of (a) 6.00 cm and (b) 3.00 cm?

79 Water in an irrigation ditch of width $w = 3.22$ m and depth $d = 1.04$ m flows with a speed of 0.207 m/s. The mass flux of the flowing water through an imaginary surface is the product of the water’s density (1000 kg/m³) and its volume flux through that surface. Find the mass flux through the following imaginary surfaces: (a) a surface of area $wd$, entirely in the water, perpendicular to the flow; (b) a surface with area $3wd/2$, of which $wd$ is in the water, perpendicular to the flow; (c) a surface of area $wd/2$, entirely in the water, perpendicular to the flow; (d) a surface of area $wd$, half in the water and half out, perpendicular to the flow; (e) a surface of area $wd$, entirely in the water, with its normal 34.0° from the direction of flow.

80 Charge of uniform surface density 8.00 nC/m² is distributed over an entire xy plane; charge of uniform surface density 3.00 nC/m² is distributed over the parallel plane defined by $z = 2.00$ m. Determine the magnitude of the electric field at any point having a $z$ coordinate of (a) 1.00 m and (b) 3.00 m.

81 A spherical ball of charged particles has a uniform charge density. In terms of the ball’s radius $R$, at what radial distances (a) inside and (b) outside the ball is the magnitude of the ball’s electric field equal to $\frac{1}{2}$ of the maximum magnitude of that field?
CHAPTER 24

Electric Potential

24-1 ELECTRIC POTENTIAL

Learning Objectives

After reading this module, you should be able to . . .

24.01 Identify that the electric force is conservative and thus has an associated potential energy.

24.02 Identify that at every point in a charged object’s electric field, the object sets up an electric potential \( V \), which is a scalar quantity that can be positive or negative depending on the sign of the object’s charge.

24.03 For a charged particle placed at a point in an object’s electric field, apply the relationship between the object’s electric potential \( V \) at that point, the particle’s charge \( q \), and the potential energy \( U \) of the particle–object system.

24.04 Convert energies between units of joules and electron-volts.

24.05 If a charged particle moves from an initial point to a final point in an electric field, apply the relationships

\[
\Delta U = q \Delta V = q(V_f - V_i).
\]

24.06 If a charged particle moves between two given points in the electric field of a charged object, identify that the amount of work done by the electric force is path independent.

24.07 If a charged particle moves through a change \( \Delta V \) in electric potential without an applied force acting on it, relate \( \Delta V \) and the change \( \Delta K \) in the particle’s kinetic energy.

24.08 If a charged particle moves through a change \( \Delta V \) in electric potential while an applied force acts on it, relate \( \Delta V \), the change \( \Delta K \) in the particle’s kinetic energy, and the work \( W_{\text{app}} \) done by the applied force.

Key Ideas

- The electric potential \( V \) at a point \( P \) in the electric field of a charged object is

\[
V = -\frac{W_c}{q_0} = \frac{U}{q_0},
\]

where \( W_c \) is the work that would be done by the electric force on a positive test charge \( q_0 \) were it brought from an infinite distance to \( P \), and \( U \) is the electric potential energy that would then be stored in the test charge–object system.

- If a particle with charge \( q \) is placed at a point where the electric potential of a charged object is \( V \), the electric potential energy \( U \) of the particle–object system is

\[
U = qV.
\]

- If the particle moves through a potential difference \( \Delta V \), the change in the electric potential energy is

\[
\Delta U = q \Delta V = q(V_f - V_i).
\]

What Is Physics?

One goal of physics is to identify basic forces in our world, such as the electric force we discussed in Chapter 21. A related goal is to determine whether a force is conservative—that is, whether a potential energy can be associated with it. The motivation for associating a potential energy with a force is that we can then
apply the principle of the conservation of mechanical energy to closed systems involving the force. This extremely powerful principle allows us to calculate the results of experiments for which force calculations alone would be very difficult. Experimentally, physicists and engineers discovered that the electric force is conservative and thus has an associated electric potential energy. In this chapter we first define this type of potential energy and then put it to use.

For a quick taste, let’s return to the situation we considered in Chapter 22: In Figure 24-1, particle 1 with positive charge \(q_1\) is located at point \(P\) near particle 2 with positive charge \(q_2\). In Chapter 22 we explained how particle 2 is able to push on particle 1 without any contact. To account for the force \(\vec{F}\) (which is a vector quantity), we defined an electric field \(\vec{E}\) (also a vector quantity) that is set up at \(P\) by particle 2. That field exists regardless of whether particle 1 is at \(P\). If we choose to place particle 1 there, the push on it is due to charge \(q_1\) and that pre-existing field \(\vec{E}\).

Here is a related problem. If we release particle 1 at \(P\), it begins to move and thus has kinetic energy. Energy cannot appear by magic, so from where does it come? It comes from the electric potential energy \(U\) associated with the force between the two particles in the arrangement of Fig. 24-1. To account for the potential energy \(U\) (which is a scalar quantity), we define an electric potential \(V\) (also a scalar quantity) that is set up at \(P\) by particle 2. The electric potential exists regardless of whether particle 1 is at \(P\). If we choose to place particle 1 there, the potential energy of the two-particle system is then due to charge \(q_1\) and that pre-existing electric potential \(V\).

Our goals in this chapter are to (1) define electric potential, (2) discuss how to calculate it for various arrangements of charged particles and objects, and (3) discuss how electric potential \(V\) is related to electric potential energy \(U\).

### Electric Potential and Electric Potential Energy

We are going to define the electric potential (or potential for short) in terms of electric potential energy, so our first job is to figure out how to measure that potential energy. Back in Chapter 8, we measured gravitational potential energy \(U\) of an object by (1) assigning \(U = 0\) for a reference configuration (such as the object at table level) and (2) then calculating the work \(W\) the gravitational force does if the object is moved up or down from that level. We then defined the potential energy as being

\[
U = -W \quad \text{(potential energy).} \tag{24-1}
\]

Let’s follow the same procedure with our new conservative force, the electric force. In Fig. 24-2a, we want to find the potential energy \(U\) associated with a positive test charge \(q_0\) located at point \(P\) in the electric field of a charged rod. First, we need a reference configuration for which \(U = 0\). A reasonable choice is for the test charge to be infinitely far from the rod, because then there is no interaction with the rod. Next, we bring the test charge in from infinity to point \(P\) to form the configuration of Fig. 24-2a. Along the way, we calculate the work done by the electric force on the test charge. The potential energy of the final configuration is then given by Eq. 24-1, where \(W\) is now the work done by the electric force. Let’s use the notation \(W_{\text{e}}\) to emphasize that the test charge is brought in from infinity. The work and thus the potential energy can be positive or negative depending on the sign of the rod’s charge.

Next, we define the electric potential \(V\) at \(P\) in terms of the work done by the electric force and the resulting potential energy:

\[
V = \frac{-W_{\text{e}}}{q_0} = \frac{U}{q_0} \quad \text{(electric potential).} \tag{24-2}
\]
That is, the electric potential is the amount of electric potential energy per unit charge when a positive test charge is brought in from infinity. The rod sets up this potential $V$ at $P$ regardless of whether the test charge (or anything else) happens to be there (Fig. 24-2b). From Eq. 24-2 we see that $V$ is a scalar quantity (because there is no direction associated with potential energy or charge) and can be positive or negative (because potential energy and charge have signs).

Repeating this procedure we find that an electric potential is set up at every point in the rod’s electric field. In fact, every charged object sets up electric potential $V$ at points throughout its electric field. If we happen to place a particle with, say, charge $q$ at a point where we know the pre-existing $V$, we can immediately find the potential energy of the configuration:

$$e\text{lectric potential energy} = (\text{particle’s charge}) \left( \frac{\text{electric potential energy}}{\text{unit charge}} \right),$$

or

$$U = qV, \quad (24-3)$$

where $q$ can be positive or negative.

**Two Cautions.** (1) The (now very old) decision to call $V$ a potential was unfortunate because the term is easily confused with potential energy. Yes, the two quantities are related (that is the point here) but they are very different and not interchangeable. (2) Electric potential is a scalar, not a vector. (When you come to the homework problems, you will rejoice on this point.)

**Language.** A potential energy is a property of a system (or configuration) of objects, but sometimes we can get away with assigning it to a single object. For example, the gravitational potential energy of a baseball hit to outfield is actually a potential energy of the baseball–Earth system (because it is associated with the force between the baseball and Earth). However, because only the baseball noticeably moves (its motion does not noticeably affect Earth), we might assign the gravitational potential energy to it alone. In a similar way, if a charged particle is placed in an electric field and has no noticeable effect on the field (or the charged object that sets up the field), we usually assign the electric potential energy to the particle alone.

**Units.** The SI unit for potential that follows from Eq. 24-2 is the joule per coulomb. This combination occurs so often that a special unit, the volt (abbreviated $V$), is used to represent it. Thus,

$$1 \text{ volt} = 1 \text{ joule per coulomb}.$$  

With two unit conversions, we can now switch the unit for electric field from newtons per coulomb to a more conventional unit:

$$1 \text{ N/C} = \left( \frac{1 \text{ N}}{1 \text{ C}} \right) \left( \frac{1 \text{ V}}{1 \text{ J/C}} \right) = \frac{1 \text{ J}}{1 \text{ N} \cdot \text{m}} = 1 \text{ V/m}.$$  

The conversion factor in the second set of parentheses comes from our definition of volt given above; that in the third set of parentheses is derived from the definition of the joule. From now on, we shall express values of the electric field in volts per meter rather than in newtons per coulomb.

**Motion Through an Electric Field**

**Change in Electric Potential.** If we move from an initial point $i$ to a second point $f$ in the electric field of a charged object, the electric potential changes by

$$\Delta V = V_f - V_i.$$
If we move a particle with charge $q$ from $i$ to $f$, then, from Eq. 24-3, the potential energy of the system changes by

$$\Delta U = q \Delta V = q(V_f - V_i). \quad (24-4)$$

The change can be positive or negative, depending on the signs of $q$ and $\Delta V$. It can also be zero, if there is no change in potential from $i$ to $f$ (the points have the same value of potential). Because the electric force is conservative, the change in potential energy $\Delta U$ between $i$ and $f$ is the same for all paths between those points (it is path independent).

**Work by the Field.** We can relate the potential energy change $\Delta U$ to the work $W$ done by the electric force as the particle moves from $i$ to $f$ by applying the general relation for a conservative force (Eq. 8-1):

$$W = -\Delta U \quad \text{(work, conservative force)}. \quad (24-5)$$

Next, we can relate that work to the change in the potential by substituting from Eq. 24-4:

$$W = -\Delta U = -q \Delta V = -q(V_f - V_i). \quad (24-6)$$

Up until now, we have always attributed work to a force but here can also say that $W$ is the work done on the particle by the electric field (because it, of course, produces the force). The work can be positive, negative, or zero. Because $\Delta U$ between any two points is path independent, so is the work $W$ done by the field. (If you need to calculate work for a difficult path, switch to an easier path—you get the same result.)

**Conservation of Energy.** If a charged particle moves through an electric field with no force acting on it other than the electric force due to the field, then the mechanical energy is conserved. Let’s assume that we can assign the electric potential energy to the particle alone. Then we can write the conservation of mechanical energy of the particle that moves from point $i$ to point $f$ as

$$U_i + K_i = U_f + K_f, \quad (24-7)$$

or

$$\Delta K = -\Delta U. \quad (24-8)$$

Substituting Eq. 24-4, we find a very useful equation for the change in the particle’s kinetic energy as a result of the particle moving through a potential difference:

$$\Delta K = -q \Delta V = -q(V_f - V_i). \quad (24-9)$$

**Work by an Applied Force.** If some force in addition to the electric force acts on the particle, we say that the additional force is an applied force or external force, which is often attributed to an external agent. Such an applied force can do work on the particle, but the force may not be conservative and thus, in general, we cannot associate a potential energy with it. We account for that work $W_{\text{app}}$ by modifying Eq. 24-7:

$$(\text{initial energy}) + (\text{work by applied force}) = (\text{final energy})$$

or

$$U_i + K_i + W_{\text{app}} = U_f + K_f. \quad (24-10)$$

Rearranging and substituting from Eq. 24-4, we can also write this as

$$\Delta K = -\Delta U + W_{\text{app}} = -q \Delta V + W_{\text{app}}. \quad (24-11)$$

The work by the applied force can be positive, negative, or zero, and thus the energy of the system can increase, decrease, or remain the same.

In the special case where the particle is stationary before and after the move, the kinetic energy terms in Eqs. 24-10 and 24-11 are zero and we have

$$W_{\text{app}} = q \Delta V \quad \text{(for } K_i = K_f). \quad (24-12)$$

In this special case, the work $W_{\text{app}}$ involves the motion of the particle through the potential difference $\Delta V$ and not a change in the particle’s kinetic energy.
By comparing Eqs. 24-6 and 24-12, we see that in this special case, the work by the applied force is the negative of the work by the field:

\[ W_{\text{app}} = -W \]  \hspace{1cm} (for \( K_i = K_f \)). \hspace{1cm} (24-13)

**Electron-volts.** In atomic and subatomic physics, energy measures in the SI unit of joules often require awkward powers of ten. A more convenient (but non-SI unit) is the electron-volt (eV), which is defined to be equal to the work required to move a single elementary charge \( e \) (such as that of an electron or proton) through a potential difference \( \Delta V \) of exactly one volt. From Eq. 24-6, we see that the magnitude of this work is \( q \Delta V \). Thus,

\[
1 \text{ eV} = e(1 \text{ V}) = (1.602 \times 10^{-19} \text{ C})(1 \text{ J/C}) = 1.602 \times 10^{-19} \text{ J}. \hspace{1cm} (24-14)
\]

**Sample Problem 24.01  Work and potential energy in an electric field**

Electrons are continually being knocked out of air molecules in the atmosphere by cosmic-ray particles coming in from space. Once released, each electron experiences an electric force \( \vec{F} \) due to the electric field \( \vec{E} \) that is produced in the atmosphere by charged particles already on Earth. Near Earth’s surface the electric field has the magnitude \( E = 150 \text{ N/C} \) and is directed downward. What is the change \( \Delta U \) in the electric potential energy of a released electron when the electric force causes it to move vertically upward through a distance \( d = 520 \text{ m} \) (Fig. 24-3)? Through what potential change does the electron move?

**KEY IDEAS**

1. The change \( \Delta U \) in the electric potential energy of the electron is related to the work \( W \) done on the electron by the electric field. Equation 24-5 \( (W = -\Delta U) \) gives the relation.
2. The work done by a constant force \( \vec{F} \) on a particle undergoing a displacement \( \vec{d} \) is

\[ W = \vec{F} \cdot \vec{d}. \]

3. The electric force and the electric field are related by the force equation \( \vec{F} = q\vec{E} \), where here \( q \) is the charge of an electron \( (=-1.6 \times 10^{-19} \text{ C}) \).

**Calculations:** Substituting the force equation into the work equation and taking the dot product yield

\[ W = q\vec{E} \cdot \vec{d} = qEd \cos \theta, \]

where \( \theta \) is the angle between the directions of \( \vec{E} \) and \( \vec{d} \). The field \( \vec{E} \) is directed downward and the displacement \( \vec{d} \) is directed upward; so \( \theta = 180^\circ \). We can now evaluate the work as

\[
W = (-1.6 \times 10^{-19} \text{ C})(150 \text{ N/C})(520 \text{ m}) \cos 180^\circ = 1.2 \times 10^{-14} \text{ J}. \hspace{1cm} (24-4)
\]

Equation 24-5 then yields

\[
\Delta U = -W = -1.2 \times 10^{-14} \text{ J}. \hspace{1cm} (Answer)
\]

This result tells us that during the 520 m ascent, the electric potential energy of the electron decreases by \( 1.2 \times 10^{-14} \text{ J} \). To find the change in electric potential, we apply Eq. 24-4:

\[
\Delta V = \frac{\Delta U}{-q} = \frac{-1.2 \times 10^{-14} \text{ J}}{-1.6 \times 10^{-19} \text{ C}} = 4.5 \times 10^4 \text{ V} = 45 \text{ kV}. \hspace{1cm} (Answer)
\]

This tells us that the electric force does work to move the electron to a higher potential.

---

**Checkpoint 1**

In the figure, we move a proton from point \( i \) to point \( f \) in a uniform electric field. Is positive or negative work done by (a) the electric field and (b) our force? (c) Does the electric potential energy increase or decrease? (d) Does the proton move to a point of higher or lower electric potential?

---

**Figure 24-3** An electron in the atmosphere is moved upward through displacement \( \vec{d} \) by an electric force \( \vec{F} \) due to an electric field \( \vec{E} \).
24-2 EQUIPOTENTIAL SURFACES AND THE ELECTRIC FIELD

Learning Objectives

After reading this module, you should be able to . . .

24.09 Identify an equipotential surface and describe how it is related to the direction of the associated electric field.

24.10 Given an electric field as a function of position, calculate the change in potential $\Delta V$ from an initial point to a final point by choosing a path between the points and integrating the dot product of the field $\vec{E}$ and a length element $d\vec{s}$ along the path.

24.11 For a uniform electric field, relate the field magnitude $E$ and the separation $\Delta x$ and potential difference $\Delta V$ between adjacent equipotential lines.

24.12 Given a graph of electric field $E$ versus position along an axis, calculate the change in potential $\Delta V$ from an initial point to a final point by graphical integration.

24.13 Explain the use of a zero-potential location.

Key Ideas

- The points on an equipotential surface all have the same electric potential. The work done on a test charge in moving it from one such surface to another is independent of the locations of the initial and final points on these surfaces and of the path that joins the points. The electric field $\vec{E}$ is always directed perpendicularly to corresponding equipotential surfaces.

- The electric potential difference between two points $i$ and $f$ is

$$V_f - V_i = -\int_i^f \vec{E} \cdot d\vec{s},$$

where the integral is taken over any path connecting the points. If the integration is difficult along any particular path, we can choose a different path along which the integration might be easier.

- If we choose $V_i = 0$, we have, for the potential at a particular point,

$$V = -\int_i^f \vec{E} \cdot d\vec{s}.$$

- In a uniform field of magnitude $E$, the change in potential from a higher equipotential surface to a lower one, separated by distance $\Delta x$, is

$$\Delta V = -E \Delta x.$$

Equipotential Surfaces

Adjacent points that have the same electric potential form an equipotential surface, which can be either an imaginary surface or a real, physical surface. No net work $W$ is done on a charged particle by an electric field when the particle moves between two points $i$ and $f$ on the same equipotential surface. This follows from Eq. 24-6, which tells us that $W$ must be zero if $V_f = V_i$. Because of the path independence of work (and thus of potential energy and potential), $W = 0$ for any path connecting points $i$ and $f$ on a given equipotential surface regardless of whether that path lies entirely on that surface.

Figure 24-4 shows a family of equipotential surfaces associated with the electric field due to some distribution of charges. The work done by the electric field on a charged particle as the particle moves from one end to the other of paths...
I and II is zero because each of these paths begins and ends on the same equipotential surface and thus there is no net change in potential. The work done as the charged particle moves from one end to the other of paths III and IV is not zero but has the same value for both these paths because the initial and final potentials are identical for the two paths; that is, paths III and IV connect the same pair of equipotential surfaces.

From symmetry, the equipotential surfaces produced by a charged particle or a spherically symmetrical charge distribution are a family of concentric spheres. For a uniform electric field, the surfaces are a family of planes perpendicular to the field lines. In fact, equipotential surfaces are always perpendicular to electric field lines and thus to \( \mathbf{E} \), which is always tangent to these lines. If \( \mathbf{E} \) were not perpendicular to an equipotential surface, it would have a component lying along that surface. This component would then do work on a charged particle as it moved along the surface. However, by Eq. 24-6 work cannot be done if the surface is truly an equipotential surface; the only possible conclusion is that \( \mathbf{E} \) must be everywhere perpendicular to the surface. Figure 24-5 shows electric field lines and cross sections of the equipotential surfaces for a uniform electric field and for the field associated with a charged particle and with an electric dipole.

**Calculating the Potential from the Field**

We can calculate the potential difference between any two points \( i \) and \( f \) in an electric field if we know the electric field vector \( \mathbf{E} \) all along any path connecting those points. To make the calculation, we find the work done on a positive test charge by the field as the charge moves from \( i \) to \( f \), and then use Eq. 24-6.

Consider an arbitrary electric field, represented by the field lines in Fig. 24-6, and a positive test charge \( q_0 \) that moves along the path shown from point \( i \) to point \( f \). At any point on the path, an electric force \( q_0 \mathbf{E} \) acts on the charge as it moves through a differential displacement \( d\mathbf{s} \). From Chapter 7, we know that the differential work \( dW \) done on a particle by a force \( \mathbf{F} \) during a displacement \( d\mathbf{s} \) is given by the dot product of the force and the displacement:

\[
dW = \mathbf{F} \cdot d\mathbf{s}.
\]

For the situation of Fig. 24-6, \( \mathbf{F} = q_0 \mathbf{E} \) and Eq. 24-15 becomes

\[
dW = q_0 \mathbf{E} \cdot d\mathbf{s}.
\]

To find the total work \( W \) done on the particle by the field as the particle moves from point \( i \) to point \( f \), we sum—via integration—the differential works done on the charge as it moves through all the displacements \( d\mathbf{s} \) along the path:

\[
W = q_0 \int_i^f \mathbf{E} \cdot d\mathbf{s}.
\]

If we substitute the total work \( W \) from Eq. 24-17 into Eq. 24-6, we find

\[
V_f - V_i = -\int_i^f \mathbf{E} \cdot d\mathbf{s}.
\]

**Figure 24-6** A test charge \( q_0 \) moves from point \( i \) to point \( f \) along the path shown in a nonuniform electric field. During a displacement \( d\mathbf{s} \), an electric force \( q_0 \mathbf{E} \) acts on the test charge. This force points in the direction of the field line at the location of the test charge.

**Figure 24-5** Electric field lines (purple) and cross sections of equipotential surfaces (gold) for (a) a uniform electric field, (b) the field due to a charged particle, and (c) the field due to an electric dipole.
CHAPTER 24  ELECTRIC POTENTIAL

Checkpoint 2

The figure here shows a family of parallel equipotential surfaces (in cross section) and five paths along which we shall move an electron from one surface to another. (a) What is the direction of the electric field associated with the surfaces? (b) For each path, is the work we do positive, negative, or zero? (c) Rank the paths according to the work we do, greatest first.
Sample Problem 24.02  Finding the potential change from the electric field

(a) Figure 24-8a shows two points $i$ and $f$ in a uniform electric field $\vec{E}$. The points lie on the same electric field line (not shown) and are separated by a distance $d$. Find the potential difference $V_f - V_i$ by moving a positive test charge $q_0$ from $i$ to $f$ along the path shown, which is parallel to the field direction.

**KEY IDEA**

We can find the potential difference between any two points in an electric field by integrating $\vec{E} \cdot \vec{ds}$ along a path connecting those two points according to Eq. 24-18.

**Calculations:** We have actually already done the calculation for such a path in the direction of an electric field line in a uniform field when we derived Eq. 24-21. With slight changes in notation, Eq. 24-21 gives us

$$V_f - V_i = -Ed.$$  (Answer)

(b) Now find the potential difference $V_f - V_i$ by moving the positive test charge $q_0$ from $i$ to $f$ along the path $icf$ shown in Fig. 24-8b.

**Calculations:** The Key Idea of (a) applies here too, except now we move the test charge along a path that consists of two lines: $ic$ and $cf$. At all points along line $ic$, the displacement $d\vec{s}$ of the test charge is perpendicular to $\vec{E}$. Thus, the angle $\theta$ between $\vec{E}$ and $d\vec{s}$ is 90°, and the dot product $\vec{E} \cdot d\vec{s}$ is 0. Equation 24-18 then tells us that points $i$ and $c$ are at the same potential: $V_c - V_i = 0$. Ah, we should have seen this coming. The points are on the same equipotential surface, which is perpendicular to the electric field lines.

For line $cf$ we have $\theta = 45^\circ$ and, from Eq. 24-18,

$$V_f - V_i = -\int_c^f \vec{E} \cdot d\vec{s} = -\int_c^f E(\cos 45^\circ) \, ds$$

$$= -E(\cos 45^\circ) \int_c^f ds.$$

The integral in this equation is just the length of line $cf$; from Fig. 24-8b, that length is $d/\cos 45^\circ$. Thus,

$$V_f - V_i = -E(\cos 45^\circ) \frac{d}{\cos 45^\circ} = -Ed.$$  (Answer)

This is the same result we obtained in (a), as it must be; the potential difference between two points does not depend on the path connecting them. Moral: When you want to find the potential difference between two points by moving a test charge between them, you can save time and work by choosing a path that simplifies the use of Eq. 24-18.

**Figure 24-8** (a) A test charge $q_0$ moves in a straight line from point $i$ to point $f$, along the direction of a uniform external electric field. (b) Charge $q_0$ moves along path $icf$ in the same electric field.

Additional examples, video, and practice available at WileyPLUS
24-3 POTENTIAL DUE TO A CHARGED PARTICLE

Learning Objectives

After reading this module, you should be able to . . .

24.14 For a given point in the electric field of a charged particle, apply the relationship between the electric potential V, the charge of the particle q, and the distance r from the particle.

24.15 Identify the correlation between the algebraic signs of the potential set up by a particle and the charge of the particle.

24.16 For points outside or on the surface of a spherically symmetric charge distribution, calculate the electric potential as if all the charge is concentrated as a particle at the center of the sphere.

24.17 Calculate the net potential at any given point due to several charged particles, identifying that algebraic addition is used, not vector addition.

24.18 Draw equipotential lines for a charged particle.

Key Ideas

- The electric potential due to a single charged particle at a distance r from that charged particle is

\[ V = \frac{1}{4\pi\varepsilon_0} \frac{q}{r} \]

where V has the same sign as q.

- The potential due to a collection of charged particles is

\[ V = \sum_{i=1}^{n} V_i = \frac{1}{4\pi\varepsilon_0} \sum_{i=1}^{n} \frac{q_i}{r_i} \]

Thus, the potential is the algebraic sum of the individual potentials, with no consideration of directions.

Potential Due to a Charged Particle

We now use Eq. 24-18 to derive, for the space around a charged particle, an expression for the electric potential V relative to the zero potential at infinity. Consider a point P at distance R from a fixed particle of positive charge q (Fig. 24-9). To use Eq. 24-18, we imagine that we move a positive test charge q₀ from point P to infinity. Because the path we take does not matter, let us choose the simplest one—a line that extends radially from the fixed particle through P to infinity.

To use Eq. 24-18, we must evaluate the dot product

\[ \vec{E} \cdot d\vec{s} = E \cos \theta ds \]  (24-22)

The electric field \( \vec{E} \) in Fig. 24-9 is directed radially outward from the fixed particle. Thus, the differential displacement \( d\vec{s} \) of the test particle along its path has the same direction as \( \vec{E} \). That means that in Eq. 24-22, angle \( \theta = 0 \) and \( \cos \theta = 1 \). Because the path is radial, let us write \( ds \) as \( dr \). Then, substituting the limits \( R \) and \( \infty \), we can write Eq. 24-18 as

\[ V_f - V_i = -\int_{R}^{\infty} E \, dr. \]  (24-23)

Next, we set \( V_f = 0 \) (at \( \infty \)) and \( V_i = V \) (at \( R \)). Then, for the magnitude of the electric field at the site of the test charge, we substitute from Eq. 22-3:

\[ E = \frac{1}{4\pi\varepsilon_0} \frac{q}{r^2}. \]  (24-24)

With these changes, Eq. 24-23 then gives us

\[ 0 - V = -\frac{q}{4\pi\varepsilon_0} \int_{R}^{\infty} \frac{1}{r^2} dr = \frac{q}{4\pi\varepsilon_0} \left[ \frac{1}{r} \right]_{R}^{\infty} \]

\[ = -\frac{1}{4\pi\varepsilon_0} \frac{q}{R}. \]  (24-25)
Solving for $V$ and switching $R$ to $r$, we then have

$$V = \frac{1}{4\pi\varepsilon_0} \frac{q}{r} \quad (24-26)$$

as the electric potential $V$ due to a particle of charge $q$ at any radial distance $r$ from the particle.

Although we have derived Eq. 24-26 for a positively charged particle, the derivation holds also for a negatively charged particle, in which case, $q$ is a negative quantity. Note that the sign of $V$ is the same as the sign of $q$:

A positively charged particle produces a positive electric potential. A negatively charged particle produces a negative electric potential.

Figure 24-10 shows a computer-generated plot of Eq. 24-26 for a positively charged particle; the magnitude of $V$ is plotted vertically. Note that the magnitude increases as $r \to 0$. In fact, according to Eq. 24-26, $V$ is infinite at $r = 0$, although Fig. 24-10 shows a finite, smoothed-off value there.

Equation 24-26 also gives the electric potential either outside or on the external surface of a spherically symmetric charge distribution. We can prove this by using one of the shell theorems of Modules 21-1 and 23-6 to replace the actual spherical charge distribution with an equal charge concentrated at its center. Then the derivation leading to Eq. 24-26 follows, provided we do not consider a point within the actual distribution.

**Potential Due to a Group of Charged Particles**

We can find the net electric potential at a point due to a group of charged particles with the help of the superposition principle. Using Eq. 24-26 with the plus or minus sign of the charge included, we calculate separately the potential resulting from each charge at the given point. Then we sum the potentials. Thus, for $n$ charges, the net potential is

$$V = \sum_{i=1}^{n} V_i = \frac{1}{4\pi\varepsilon_0} \sum_{i=1}^{n} \frac{q_i}{r_i} \quad (n \text{ charged particles}) \quad (24-27)$$

Here $q_i$ is the value of the $i$th charge and $r_i$ is the radial distance of the given point from the $i$th charge. The sum in Eq. 24-27 is an *algebraic sum*, not a vector sum like the sum that would be used to calculate the electric field resulting from a group of charged particles. Herein lies an important computational advantage of potential over electric field: It is a lot easier to sum several scalar quantities than to sum several vector quantities whose directions and components must be considered.

**Checkpoint 3**

The figure here shows three arrangements of two protons. Rank the arrangements according to the net electric potential produced at point $P$ by the protons, greatest first.
Sample Problem 24.03  Net potential of several charged particles

What is the electric potential at point $P$, located at the center of the square of charged particles shown in Fig. 24-11a? The distance $d$ is 1.3 m, and the charges are

$$q_1 = +12 \text{ nC}, \quad q_3 = +31 \text{ nC},$$

$$q_2 = -24 \text{ nC}, \quad q_4 = +17 \text{ nC}.$$

KEY IDEA

The electric potential $V$ at point $P$ is the algebraic sum of the electric potentials contributed by the four particles.

![Figure 24-11](a) Four charged particles. (b) The closed curve is a (roughly drawn) cross section of the equipotential surface that contains point $P$.

Sample Problem 24.04  Potential is not a vector, orientation is irrelevant

(a) In Fig. 24-12a, 12 electrons (of charge $-e$) are equally spaced and fixed around a circle of radius $R$. Relative to $V = 0$ at infinity, what are the electric potential and electric field at the center $C$ of the circle due to these electrons?

KEY IDEAS

(1) The electric potential $V$ at $C$ is the algebraic sum of the electric potentials contributed by all the electrons. Because electric potential is a scalar, the orientations of the electrons do not matter. (2) The electric field at $C$ is a vector quantity and thus the orientation of the electrons is important.

![Figure 24-12](a) Twelve electrons uniformly spaced around a circle. (b) The electrons nonuniformly spaced along an arc of the original circle.

Calculations: Because the electrons all have the same negative charge $-e$ and are all the same distance $R$ from $C$, Eq. 24-27 gives us

$$V = -12 \frac{1}{4\pi\varepsilon_0} \frac{e}{R}.$$  \hspace{1cm} \text{(Answer) \hspace{1cm} (24-28)}$$

Because of the symmetry of the arrangement in Fig. 24-12a, the electric field vector at $C$ due to any given electron is canceled by the field vector due to the electron that is diametrically opposite it. Thus, at $C$,

$$\vec{E} = 0.$$  \hspace{1cm} \text{(Answer)}

(b) The electrons are moved along the circle until they are nonuniformly spaced over a 120° arc (Fig. 24-12b). At $C$, find the electric potential and describe the electric field.

Reasoning: The potential is still given by Eq. 24-28, because the distance between $C$ and each electron is unchanged and orientation is irrelevant. The electric field is no longer zero, however, because the arrangement is no longer symmetric. A net field is now directed toward the charge distribution.
24-4 POTENTIAL DUE TO AN ELECTRIC DIPOLE

Learning Objectives
After reading this module, you should be able to . . .

24.19 Calculate the potential \( V \) at any given point due to an electric dipole, in terms of the magnitude \( p \) of the dipole moment or the product of the charge separation \( d \) and the magnitude \( q \) of either charge.

24.20 For an electric dipole, identify the locations of positive potential, negative potential, and zero potential.

24.21 Compare the decrease in potential with increasing distance for a single charged particle and an electric dipole.

Key Idea

- At a distance \( r \) from an electric dipole with dipole moment magnitude \( p = qd \), the electric potential of the dipole is

\[
V = \frac{1}{4 \pi \varepsilon_0} \frac{p \cos \theta}{r^2}
\]

for \( r \gg d \); the angle \( \theta \) lies between the dipole moment vector and a line extending from the dipole midpoint to the point of measurement.

Potential Due to an Electric Dipole

Now let us apply Eq. 24-27 to an electric dipole to find the potential at an arbitrary point \( P \) in Fig. 24-13a. At \( P \), the positively charged particle (at distance \( r_{(+)\text{}} \)) sets up potential \( V_{(+)\text{}} \) and the negatively charged particle (at distance \( r_{(-)} \)) sets up potential \( V_{(-)} \). Then the net potential at \( P \) is given by Eq. 24-27 as

\[
V = \sum_{i=1}^{2} V_i = V_{(+)\text{}} + V_{(-)} = \frac{1}{4 \pi \varepsilon_0} \left( \frac{q}{r_{(+)\text{}}} + \frac{-q}{r_{(-)}\text{}} \right)
\]

\[
= \frac{q}{4 \pi \varepsilon_0} \frac{r_{(-)} - r_{(+)\text{}}}{r_{(-)}r_{(+)\text{}}}. 
\] (24-29)

Naturally occurring dipoles—such as those possessed by many molecules—are quite small; so we are usually interested only in points that are relatively far from the dipole, such that \( r \gg d \), where \( d \) is the distance between the charges and \( r \) is the distance from the dipole’s midpoint to \( P \). In that case, we can approximate the two lines to \( P \) as being parallel and their length difference as being the leg of a right triangle with hypotenuse \( d \) (Fig. 24-13b). Also, that difference is so small that the product of the lengths is approximately \( r^2 \). Thus,

\[
r_{(-)} - r_{(+)\text{}} \approx d \cos \theta \quad \text{and} \quad r_{(-)}r_{(+)\text{}} \approx r^2.
\]

If we substitute these quantities into Eq. 24-29, we can approximate \( V \) to be

\[
V = \frac{q}{4 \pi \varepsilon_0} \frac{d \cos \theta}{r^2},
\]

where \( \theta \) is measured from the dipole axis as shown in Fig. 24-13a. We can now write \( V \) as

\[
V = \frac{1}{4 \pi \varepsilon_0} \frac{p \cos \theta}{r^2} \quad \text{(electric dipole)},
\] (24-30)

in which \( p (= qd) \) is the magnitude of the electric dipole moment \( \vec{p} \) defined in Module 22-3. The vector \( \vec{p} \) is directed along the dipole axis, from the negative to the positive charge. (Thus, \( \theta \) is measured from the direction of \( \vec{p} \).) We use this vector to report the orientation of an electric dipole.

\[\text{Figure 24-13} \quad (a) \text{Point} \ P \text{is a distance} \ r \text{from the midpoint} \ O \text{of a dipole. The line} \ OP \text{makes an angle} \ \theta \text{with the dipole axis.} \]
\[\text{(b) If} \ P \text{is far from the dipole, the lines of lengths} \ r_{(+)\text{}} \text{and} \ r_{(-)} \text{are approximately parallel to the line of length} \ r, \text{and the dashed black line is approximately perpendicular to the line of length} \ r_{(-)}.\]
CHAPTER 24  ELECTRIC POTENTIAL

Potential Due to a Continuous Charge Distribution

When a charge distribution $q$ is continuous (as on a uniformly charged thin rod or disk), we cannot use the summation of Eq. 24-27 to find the potential $V$ at a point $P$. Instead, we must choose a differential element of charge $dq$, determine the potential $dV$ at $P$ due to $dq$, and then integrate over the entire charge distribution.

Let us again take the zero of potential to be at infinity. If we treat the element of charge $dq$ as a particle, then we can use Eq. 24-26 to express the potential $dV$ at point $P$ due to $dq$:

$$dV = \frac{1}{4\pi\varepsilon_0} \frac{dq}{r}$$

(positive or negative $dq$).

Here $r$ is the distance between $P$ and $dq$. To find the total potential $V$ at $P$, we
integrate to sum the potentials due to all the charge elements:

\[ V = \int dV = \frac{1}{4\pi e_0} \int \frac{dq}{r}. \]  (24-32)

The integral must be taken over the entire charge distribution. Note that because the electric potential is a scalar, there are no vector components to consider in Eq. 24-32.

We now examine two continuous charge distributions, a line and a disk.

**Line of Charge**

In Fig. 24-15a, a thin nonconducting rod of length \( L \) has a positive charge of uniform linear density \( \lambda \). Let us determine the electric potential \( V \) due to the rod at point \( P \), a perpendicular distance \( d \) from the left end of the rod.

We consider a differential element \( dx \) of the rod as shown in Fig. 24-15b. This (or any other) element of the rod has a differential charge of

\[ dq = \lambda \, dx. \]  (24-33)

This element produces an electric potential \( dV \) at point \( P \), which is a distance \( r = (x^2 + d^2)^{1/2} \) from the element (Fig. 24-15c). Treating the element as a point charge, we can use Eq. 24-31 to write the potential \( dV \) as

\[ dV = \frac{1}{4\pi e_0} \frac{dq}{r} = \frac{1}{4\pi e_0} \frac{\lambda \, dx}{(x^2 + d^2)^{1/2}}. \]  (24-34)

---

**Figure 24-15** (a) A thin, uniformly charged rod produces an electric potential \( V \) at point \( P \). (b) An element can be treated as a particle. (c) The potential at \( P \) due to the element depends on the distance \( r \). We need to sum the potentials due to all the elements, from the left side (d) to the right side (e).
Since the charge on the rod is positive and we have taken \( V = 0 \) at infinity, we know from Module 24-3 that \( dV \) in Eq. 24-34 must be positive.

We now find the total potential \( V \) produced by the rod at point \( P \) by integrating Eq. 24-34 along the length of the rod, from \( x = 0 \) to \( x = L \) (Figs. 24-15d and e), using integral 17 in Appendix E. We find

\[
V = \int dV = \int_0^L \frac{1}{4\pi\varepsilon_0} \frac{\lambda}{(x^2 + d^2)^{1/2}} \, dx \\
= \frac{\lambda}{4\pi\varepsilon_0} \int_0^L \frac{dx}{(x^2 + d^2)^{1/2}} \\
= \frac{\lambda}{4\pi\varepsilon_0} \left[ \ln \left( x + (x^2 + d^2)^{1/2} \right) \right]_0^L \\
= \frac{\lambda}{4\pi\varepsilon_0} \left[ \ln \left( L + (L^2 + d^2)^{1/2} \right) - \ln d \right].
\]

We can simplify this result by using the general relation \( \ln A - \ln B = \ln(A/B) \). We then find

\[
V = \frac{\lambda}{4\pi\varepsilon_0} \ln \left[ \frac{L + (L^2 + d^2)^{1/2}}{d} \right]. \tag{24-35}
\]

Because \( V \) is the sum of positive values of \( dV \), it too is positive, consistent with the logarithm being positive for an argument greater than 1.

**Charged Disk**

In Module 22-5, we calculated the magnitude of the electric field at points on the central axis of a plastic disk of radius \( R \) that has a uniform charge density \( \sigma \) on one surface. Here we derive an expression for \( V(z) \), the electric potential at any point on the central axis. Because we have a circular distribution of charge on the disk, we could start with a differential element that occupies angle \( d\theta \) and radial distance \( dr \). We would then need to set up a two-dimensional integration. However, let’s do something easier.

In Fig. 24-16, consider a differential element consisting of a flat ring of radius \( R' \) and radial width \( dR' \). Its charge has magnitude

\[
dq = \sigma(2\pi R')(dR'),
\]

in which \((2\pi R')(dR')\) is the upper surface area of the ring. All parts of this charged element are the same distance \( r \) from point \( P \) on the disk’s axis. With the aid of Fig. 24-16, we can use Eq. 24-31 to write the contribution of this ring to the electric potential at \( P \) as

\[
dV = \frac{1}{4\pi\varepsilon_0} \frac{dq}{r} = \frac{1}{4\pi\varepsilon_0} \frac{\sigma(2\pi R')(dR')}{\sqrt{z^2 + R'^2}}. \tag{24-36}
\]

We find the net potential at \( P \) by adding (via integration) the contributions of all the rings from \( R' = 0 \) to \( R' = R \):

\[
V = \int dV = \frac{\sigma}{2\varepsilon_0} \int_0^R \frac{R' \, dR'}{\sqrt{z^2 + R'^2}} = \frac{\sigma}{2\varepsilon_0} (\sqrt{z^2 + R^2} - z). \tag{24-37}
\]

Note that the variable in the second integral of Eq. 24-37 is \( R' \) and not \( z \), which remains constant while the integration over the surface of the disk is carried out. (Note also that, in evaluating the integral, we have assumed that \( z \geq 0 \).)
24-6 CALCULATING THE FIELD FROM THE POTENTIAL

Learning Objectives

After reading this module, you should be able to . . .

24.23 Given an electric potential as a function of position along an axis, find the electric field along that axis.
24.24 Given a graph of electric potential versus position along an axis, determine the electric field along the axis.
24.25 For a uniform electric field, relate the field magnitude \( E \) and the separation \( \Delta x \) and potential difference \( \Delta V \) between adjacent equipotential lines.
24.26 Relate the direction of the electric field and the directions in which the potential decreases and increases.

Key Ideas

- The component of the electric field \( \vec{E} \) in any direction is the negative of the rate at which the potential changes with distance in that direction:

\[
E_x = -\frac{\partial V}{\partial s},
\]

- The \( x \), \( y \), and \( z \) components of \( \vec{E} \) may be found from:

\[
\begin{align*}
E_x &= -\frac{\partial V}{\partial x}, \\
E_y &= -\frac{\partial V}{\partial y}, \\
E_z &= -\frac{\partial V}{\partial z}.
\end{align*}
\]

When \( \vec{E} \) is uniform, all this reduces to

\[
E = -\frac{\Delta V}{\Delta s},
\]

where \( s \) is perpendicular to the equipotential surfaces.

- The electric field is zero parallel to an equipotential surface.

Calculating the Field from the Potential

In Module 24-2, you saw how to find the potential at a point \( f \) if you know the electric field along a path from a reference point to point \( f \). In this module, we propose to go the other way—that is, to find the electric field when we know the potential. As Fig. 24-5 shows, solving this problem graphically is easy: If we know the potential \( V \) at all points near an assembly of charges, we can draw in a family of equipotential surfaces. The electric field lines, sketched perpendicular to those surfaces, reveal the variation of the potential \( V \). What we are seeking here is the mathematical equivalent of this graphical procedure.

Figure 24-17 shows cross sections of a family of closely spaced equipotential surfaces, the potential difference between each pair of adjacent surfaces being \( dV \). As the figure suggests, the field \( \vec{E} \) at any point \( P \) is perpendicular to the equipotential surface through \( P \).

Suppose that a positive test charge \( q_0 \) moves through a displacement \( d\vec{s} \) from one equipotential surface to the adjacent surface. From Eq. 24-6, we see that the work the electric field does on the test charge during the move is \(-q_0 \cdot dV\). From Eq. 24-16 and Fig. 24-17, we see that the work done by the electric field may also be written as the scalar product \((q_0 \vec{E}) \cdot d\vec{s}\), or \(q_0 E \cos \theta \cdot ds\). Equating these two expressions for the work yields

\[
-q_0 \cdot dV = q_0 E \cos \theta \cdot ds,
\]

or

\[
E \cos \theta = -\frac{dV}{ds}.
\]

Since \( E \cos \theta \) is the component of \( \vec{E} \) in the direction of \( d\vec{s} \), Eq. 24-39 becomes

\[
E_x = -\frac{\partial V}{\partial s}.
\]

We have added a subscript to \( E \) and switched to the partial derivative symbols to emphasize that Eq. 24-40 involves only the variation of \( V \) along a specified axis (here called the \( s \) axis) and only the component of \( \vec{E} \) along that axis. In words, Eq. 24-40 (which is essentially the reverse operation of Eq. 24-18) states:
The component of \( \vec{E} \) in any direction is the negative of the rate at which the electric potential changes with distance in that direction.

If we take the \( s \) axis to be, in turn, the \( x \), \( y \), and \( z \) axes, we find that the \( x \), \( y \), and \( z \) components of \( \vec{E} \) at any point are

\[
E_x = -\frac{\partial V}{\partial x}; \quad E_y = -\frac{\partial V}{\partial y}; \quad E_z = -\frac{\partial V}{\partial z}. \tag{24-41}
\]

Thus, if we know \( V \) for all points in the region around a charge distribution — that is, if we know the function \( V(x, y, z) \) — we can find the components of \( \vec{E} \), and thus \( \vec{E} \) itself, at any point by taking partial derivatives.

For the simple situation in which the electric field \( \vec{E} \) is uniform, Eq. 24-40 becomes

\[
E = -\frac{\Delta V}{\Delta s}, \tag{24-42}
\]

where \( s \) is perpendicular to the equipotential surfaces. The component of the electric field is zero in any direction parallel to the equipotential surfaces because there is no change in potential along the surfaces.

**Checkpoint 5**

The figure shows three pairs of parallel plates with the same separation, and the electric potential of each plate. The electric field between the plates is uniform and perpendicular to the plates. (a) Rank the pairs according to the magnitude of the electric field between the plates, greatest first. (b) For which pair is the electric field pointing rightward? (c) If an electron is released midway between the third pair of plates, does it remain there, move rightward at constant speed, move leftward at constant speed, accelerate rightward, or accelerate leftward?

**Sample Problem 24.05  Finding the field from the potential**

The electric potential at any point on the central axis of a uniformly charged disk is given by Eq. 24-37,

\[
V = \frac{\sigma}{2\varepsilon_0} (\sqrt{z^2 + R^2} - z).
\]

Starting with this expression, derive an expression for the electric field at any point on the axis of the disk.

**KEY IDEAS**

We want the electric field \( \vec{E} \) as a function of distance \( z \) along the axis of the disk. For any value of \( z \), the direction of \( \vec{E} \) must be along that axis because the disk has circular symmetry about that axis. Thus, we want the component \( E_z \) of \( \vec{E} \) in the direction of \( z \). This component is the negative of the rate at which the electric potential changes with distance \( z \).

**Calculation:** Thus, from the last of Eqs. 24-41, we can write

\[
E_z = -\frac{\partial V}{\partial z} = -\frac{\sigma}{2\varepsilon_0} \frac{d}{dz} (\sqrt{z^2 + R^2} - z)
= -\frac{\sigma}{2\varepsilon_0} \left( 1 - \frac{z}{\sqrt{z^2 + R^2}} \right). \tag{Answer}
\]

This is the same expression that we derived in Module 22-5 by integration, using Coulomb’s law.
Learning Objectives

After reading this module, you should be able to . . .

24.27 Identify that the total potential energy of a system of charged particles is equal to the work an applied force must do to assemble the system, starting with the particles infinitely far apart.

24.28 Calculate the potential energy of a pair of charged particles.

24.29 Identify that if a system has more than two charged particles, then the system’s total potential energy is equal to the sum of the potential energies of every pair of the particles.

24.30 Apply the principle of the conservation of mechanical energy to a system of charged particles.

24.31 Calculate the escape speed of a charged particle from a system of charged particles (the minimum initial speed required to move infinitely far from the system).

Electric Potential Energy of a System of Charged Particles

In this module we are going to calculate the potential energy of a system of two charged particles and then briefly discuss how to expand the result to a system of more than two particles. Our starting point is to examine the work we must do (as an external agent) to bring together two charged particles that are initially infinitely far apart and that end up near each other and stationary. If the two particles have the same sign of charge, we must fight against their mutual repulsion. Our work is then positive and results in a positive potential energy for the final two-particle system. If, instead, the two particles have opposite signs of charge, our job is easy because of the mutual attraction of the particles. Our work is then negative and results in a negative potential energy for the system.

Let’s follow this procedure to build the two-particle system in Fig. 24-18, where particle 1 (with positive charge \( q_1 \)) and particle 2 (with positive charge \( q_2 \)) have separation \( r \). Although both particles are positively charged, our result will apply also to situations where they are both negatively charged or have different signs.

We start with particle 2 fixed in place and particle 1 infinitely far away, with an initial potential energy \( U_i \) for the two-particle system. Next we bring particle 1 to its final position, and then the system’s potential energy is \( U_f \). Our work changes the system’s potential energy by \( \Delta U = U_f - U_i \).

With Eq. 24-4 (\( \Delta U = q(V_f - V_i) \)), we can relate \( \Delta U \) to the change in potential through which we move particle 1:

\[
U_f - U_i = q_1(V_f - V_i).
\]  

(24-43)

Let’s evaluate these terms. The initial potential energy is \( U_i = 0 \) because the particles are in the reference configuration (as discussed in Module 24-1). The two potentials in Eq. 24-43 are due to particle 2 and are given by Eq. 24-26:

\[
V = \frac{1}{4\pi\varepsilon_0} \frac{q_2}{r}.
\]  

(24-44)

This tells us that when particle 1 is initially at distance \( r = \infty \), the potential at its location is \( V_i = 0 \). When we move it to the final position at distance \( r \), the potential at its location is

\[
V_f = \frac{1}{4\pi\varepsilon_0} \frac{q_2}{r}.
\]  

(24-45)
Substituting these results into Eq. 24-43 and dropping the subscript \( f \), we find that the final configuration has a potential energy of

\[
U = \frac{1}{4\pi \varepsilon_0} \frac{q_1 q_2}{r} \quad \text{(two-particle system).} \tag{24-46}
\]

Equation 24-46 includes the signs of the two charges. If the two charges have the same sign, \( U \) is positive. If they have opposite signs, \( U \) is negative.

If we next bring in a third particle, with charge \( q_3 \), we repeat our calculation, starting with particle 3 at an infinite distance and then bringing it to a final position at distance \( r_{31} \) from particle 1 and distance \( r_{32} \) from particle 2. At the final position, the potential \( V_f \) at the location of particle 3 is the algebraic sum of the potential \( V_1 \) due to particle 1 and the potential \( V_2 \) of particle 2. When we work out the algebra, we find that

\[
\text{The total potential energy of a system of particles is the sum of the potential energies for every pair of particles in the system.}
\]

This result applies to a system for any given number of particles.

Now that we have an expression for the potential energy of a system of particles, we can apply the principle of the conservation of energy to the system as expressed in Eq. 24-10. For example, if the system consists of many particles, we might consider the kinetic energy (and the associated escape speed) required of one of the particles to escape from the rest of the particles.

**Sample Problem 24.06**  
**Potential energy of a system of three charged particles**

Figure 24-19 shows three charged particles held in fixed positions by forces that are not shown. What is the electric potential energy \( U \) of this system of charges? Assume that \( d = 12 \text{ cm} \) and that

\[
q_1 = +q, \quad q_2 = -4q, \quad \text{and} \quad q_3 = +2q,
\]

in which \( q = 150 \text{ nC} \).

**KEY IDEA**

The potential energy \( U \) of the system is equal to the work we must do to assemble the system, bringing in each charge from an infinite distance.

**Calculations:** Let’s mentally build the system of Fig. 24-19, starting with one of the charges, say \( q_1 \), in place and the others at infinity. Then we bring another one, say \( q_2 \), from infinity and put it in place. From Eq. 24-46 with \( d \) substituted for \( r \), the potential energy \( U_{12} \) associated with the pair of charges \( q_1 \) and \( q_2 \) is

\[
U_{12} = \frac{1}{4\pi \varepsilon_0} \frac{q_1 q_2}{d}.
\]

We then bring the last charge \( q_3 \) in from infinity and put it in place. The work that we must do in this last step is equal to the sum of the work we must do to bring \( q_3 \) near \( q_1 \) and the work we must do to bring it near \( q_2 \). From Eq. 24-46, with \( d \) substituted for \( r \), that sum is

\[
W_{13} + W_{23} = U_{13} + U_{23} = \frac{1}{4\pi \varepsilon_0} \frac{q_1 q_3}{d} + \frac{1}{4\pi \varepsilon_0} \frac{q_2 q_3}{d}.
\]

The total potential energy \( U \) of the three-charge system is the sum of the potential energies associated with the three pairs of charges. This sum (which is actually independent of the order in which the charges are brought together) is

\[
\text{Energy is associated with each pair of particles.}
\]

**Figure 24-19**  
Three charges are fixed at the vertices of an equilateral triangle. What is the electric potential energy of the system?
The system's initial electric potential energy

\[ U = U_{12} + U_{13} + U_{23} \]

\[ = \frac{1}{4\pi\varepsilon_0} \left( \frac{(+q)(-4q)}{d} + \frac{(+q)(+2q)}{d} + \frac{(-4q)(+2q)}{d} \right) \]

\[ = -\frac{10q^2}{4\pi\varepsilon_0 d} \]

\[ = -\frac{(8.99 \times 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2)(10)(150 \times 10^{-9} \text{ C})^2}{0.12 \text{ m}} \]

\[ = -1.7 \times 10^{-2} \text{ J} = -17 \text{ mJ}. \] (Answer)

The negative potential energy means that negative work would have to be done to assemble this structure, starting with the three charges infinitely separated and at rest. Put another way, an external agent would have to do 17 mJ of positive work to disassemble the structure completely, ending with the three charges infinitely far apart.

The lesson here is this: If you are given an assembly of charged particles, you can find the potential energy of the assembly by finding the potential of every possible pair of the particles and then summing the results.

**Sample Problem 24.07 Conservation of mechanical energy with electric potential energy**

An alpha particle (two protons, two neutrons) moves into a stationary gold atom (79 protons, 118 neutrons), passing through the electron region that surrounds the gold nucleus like a shell and headed directly toward the nucleus (Fig. 24-20). The alpha particle slows until it momentarily stops when its center is at radial distance \( r = 9.23 \text{ fm} \) from the nuclear center. Then it moves back along its incoming path. (Because the gold nucleus is much more massive than the alpha particle, we can assume the gold nucleus does not move.) What was the kinetic energy \( K_i \) of the alpha particle when it was initially far away (hence external to the gold atom)? Assume that the only force acting between the alpha particle and the gold nucleus is the (electrostatic) Coulomb force and treat each as a single charged particle.

**KEY IDEA**

During the entire process, the mechanical energy of the alpha particle + gold atom system is conserved.

**Reasoning:** When the alpha particle is outside the atom, the system's initial electric potential energy \( U_i \) is zero because the atom has an equal number of electrons and protons, which produce a net electric field of zero. However, once the alpha particle passes through the electron region surrounding the nucleus on its way to the nucleus, the electric field due to the electrons goes to zero. The reason is that the electrons act like a closed spherical shell of uniform negative charge and, as discussed in Module 23-6, such a shell produces zero electric field in the space it encloses. The alpha particle still experiences the electric field of the protons in the nucleus, which produces a repulsive force on the protons within the alpha particle.

\[ K_i + U_i = K_f + U_f. \] (24-47)

We know two values: \( U_i = 0 \) and \( K_f = 0 \). We also know that the potential energy \( U_f \) at the stopping point is given by the right side of Eq. 24-46, with \( q_1 = 2e, q_2 = 79e \) (in which \( e \) is the elementary charge, \( 1.60 \times 10^{-19} \text{ C} \)), and \( r = 9.23 \text{ fm} \). Thus, we can rewrite Eq. 24-47 as

\[ K_f = \frac{1}{4\pi\varepsilon_0} \frac{(2e)(79e)}{9.23 \text{ fm}} \]

\[ = \frac{(8.99 \times 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2)(158)(1.60 \times 10^{-19} \text{ C})^2}{9.23 \times 10^{-15} \text{ m}} \]

\[ = 3.94 \times 10^{-12} \text{ J} = 24.6 \text{ MeV}. \] (Answer)
CHAPTER 24  ELECTRIC POTENTIAL

24-8 POTENTIAL OF A CHARGED ISOLATED CONDUCTOR

Learning Objectives

After reading this module, you should be able to . . .

24.32 Identify that an excess charge placed on an isolated conductor (or connected isolated conductors) will distribute itself on the surface of the conductor so that all points of the conductor come to the same potential.

24.33 For an isolated spherical conducting shell, sketch graphs of the potential and the electric field magnitude versus distance from the center, both inside and outside the shell.

24.34 For an isolated spherical conducting shell, identify that internally the electric field is zero and the electric potential has the same value as the surface and that externally the electric field and the electric potential have values as though all of the shell’s charge is concentrated as a particle at its center.

24.35 For an isolated cylindrical conducting shell, identify that internally the electric field is zero and the electric potential has the same value as the surface and that externally the electric field and the electric potential have values as though all of the cylinder’s charge is concentrated as a line of charge on the central axis.

Key Ideas

● An excess charge placed on a conductor will, in the equilibrium state, be located entirely on the outer surface of the conductor.

● The entire conductor, including interior points, is at a uniform potential.

● If an isolated charged conductor is placed in an external electric field, then at every internal point, the electric field due to the charge cancels the external electric field that otherwise would have been there.

● Also, the net electric field at every point on the surface is perpendicular to the surface.

Potential of a Charged Isolated Conductor

In Module 23-3, we concluded that \( \vec{E} = 0 \) for all points inside an isolated conductor. We then used Gauss’ law to prove that an excess charge placed on an isolated conductor lies entirely on its surface. (This is true even if the conductor has an empty internal cavity.) Here we use the first of these facts to prove an extension of the second:

An excess charge placed on an isolated conductor will distribute itself on the surface of that conductor so that all points of the conductor—whether on the surface or inside—come to the same potential. This is true even if the conductor has an internal cavity and even if that cavity contains a net charge.

Our proof follows directly from Eq. 24-18, which is

\[
V_f - V_i = -\int_{i}^{f} \vec{E} \cdot d\vec{s}
\]

Since \( \vec{E} = 0 \) for all points within a conductor, it follows directly that \( V_f = V_i \) for all possible pairs of points \( i \) and \( f \) in the conductor.

Figure 24-21a is a plot of potential against radial distance \( r \) from the center for an isolated spherical conducting shell of 1.0 m radius, having a charge of 1.0 \( \mu \)C. For points outside the shell, we can calculate \( V(r) \) from Eq. 24-26 because the charge \( q \) behaves for such external points as if it were concentrated at the center of the shell. That equation holds right up to the surface of the shell. Now let us push a small test charge through the shell—assuming a small hole exists—to its center. No extra work is needed to do this because no net electric force acts on the test charge once it is inside the shell. Thus, the potential at all points inside the shell has the same value as that on the surface, as Fig. 24-21a shows.

Figure 24-21  (a) A plot of \( V(r) \) both inside and outside a charged spherical shell of radius 1.0 m. (b) A plot of \( E(r) \) for the same shell.
Figure 24-21b shows the variation of electric field with radial distance for the same shell. Note that $E = 0$ everywhere inside the shell. The curves of Fig. 24-21b can be derived from the curve of Fig. 24-21a by differentiating with respect to $r$, using Eq. 24-40 (recall that the derivative of any constant is zero). The curve of Fig. 24-21a can be derived from the curves of Fig. 24-21b by integrating with respect to $r$, using Eq. 24-19.

**Spark Discharge from a Charged Conductor**

On nonspherical conductors, a surface charge does not distribute itself uniformly over the surface of the conductor. At sharp points or sharp edges, the surface charge density—and thus the external electric field, which is proportional to it—may reach very high values. The air around such sharp points or edges may become ionized, producing the corona discharge that golfers and mountaineers see on the tips of bushes, golf clubs, and rock hammers when thunderstorms threaten. Such corona discharges, like hair that stands on end, are often the precursors of lightning strikes. In such circumstances, it is wise to enclose yourself in a cavity inside a conducting shell, where the electric field is guaranteed to be zero. A car (unless it is a convertible or made with a plastic body) is almost ideal (Fig. 24-22).

**Isolated Conductor in an External Electric Field**

If an isolated conductor is placed in an external electric field, as in Fig. 24-23, all points of the conductor still come to a single potential regardless of whether the conductor has an excess charge. The free conduction electrons distribute themselves on the surface in such a way that the electric field they produce at interior points cancels the external electric field that would otherwise be there. Furthermore, the electron distribution causes the net electric field at all points on the surface to be perpendicular to the surface. If the conductor in Fig. 24-23 could be somehow removed, leaving the surface charges frozen in place, the internal and external electric field would remain absolutely unchanged.

**Review & Summary**

**Electric Potential** The electric potential $V$ at a point $P$ in the electric field of a charged object is

$$V = \frac{-W}{q_0} = \frac{U}{q_0},$$

(24-2)

where $W$ is the work that would be done by the electric force on a positive test charge were it brought from an infinite distance to $P$, and $U$ is the potential energy that would then be stored in the test charge–object system.

**Electric Potential Energy** If a particle with charge $q$ is placed at a point where the electric potential of a charged object is $V$, the electric potential energy $U$ of the particle–object system is

$$U = qV.$$  

(24-3)

If the particle moves through a potential difference $\Delta V$, the change in the electric potential energy is

$$\Delta U = q \Delta V = q(V_f - V_i).$$  

(24-4)

**Mechanical Energy** If a particle moves through a change $\Delta V$ in electric potential without an applied force acting on it, applying the conservation of mechanical energy gives the change in kinetic energy as

$$\Delta K = -q \Delta V.$$  

(24-9)

If, instead, an applied force acts on the particle, doing work $W_{\text{app}}$, the change in kinetic energy is

$$\Delta K = -q \Delta V + W_{\text{app}}.$$  

(24-11)

In the special case when $\Delta K = 0$, the work of an applied force
involves only the motion of the particle through a potential difference:

\[ W_{\text{app}} = q \Delta V \quad \text{(for } K_i = K_f) \]  

(24-12)

**Equipotential Surfaces** The points on an equipotential surface all have the same electric potential. The work done on a test charge in moving it from one such surface to another is independent of the locations of the initial and final points on these surfaces and of the path that joins the points. The electric field \( \vec{E} \) is always directed perpendicularly to corresponding equipotential surfaces.

**Finding \( V \) from \( \vec{E} \)** The electric potential difference between two points \( i \) and \( f \) is

\[ V_f - V_i = -\int_{s}^{f} \vec{E} \cdot d\vec{s}, \]  

(24-18)

where the integral is taken over any path connecting the points. If the integration is difficult along any particular path, we can choose a different path along which the integration might be easier. If we choose \( V_i = 0 \), we have, for the potential at a particular point,

\[ V = -\int_{s}^{f} \vec{E} \cdot d\vec{s}. \]  

(24-19)

In the special case of a uniform field of magnitude \( E \), the potential change between two adjacent (parallel) equipotential lines separated by distance \( \Delta x \) is

\[ \Delta V = -E \Delta x. \]  

(24-21)

**Potential Due to a Charged Particle** The electric potential due to a single charged particle at a distance \( r \) from that particle is

\[ V = \frac{1}{4\pi\varepsilon_0} \frac{q}{r}, \]  

(24-26)

where \( V \) has the same sign as \( q \). The potential due to a collection of charged particles is

\[ V = \sum_{i=1}^{n} V_i = \frac{1}{4\pi\varepsilon_0} \sum_{i=1}^{n} \frac{q_i}{r_i}. \]  

(24-27)

**Potential Due to an Electric Dipole** At a distance \( r \) from an electric dipole with dipole moment magnitude \( p = qd \), the electric potential of the dipole is

\[ V = \frac{1}{4\pi\varepsilon_0} \frac{p \cos \theta}{r^2} \]  

(24-30)

for \( r \gg d \); the angle \( \theta \) is defined in Fig. 24-13.

**Potential Due to a Continuous Charge Distribution** For a continuous distribution of charge, Eq. 24-27 becomes

\[ V = \frac{1}{4\pi\varepsilon_0} \int \frac{dq}{r}, \]  

(24-32)

in which the integral is taken over the entire distribution.

**Calculating \( \vec{E} \) from \( V \)** The component of \( \vec{E} \) in any direction is the negative of the rate at which the potential changes with distance in that direction:

\[ E_i = -\frac{\partial V}{\partial s}. \]  

(24-40)

The \( x \), \( y \), and \( z \) components of \( \vec{E} \) may be found from

\[ E_x = -\frac{\partial V}{\partial x}; \quad E_y = -\frac{\partial V}{\partial y}; \quad E_z = -\frac{\partial V}{\partial z}. \]  

(24-41)

When \( \vec{E} \) is uniform, Eq. 24-40 reduces to

\[ E = -\frac{\Delta V}{\Delta s}, \]  

(24-42)

where \( s \) is perpendicular to the equipotential surfaces.

**Electric Potential Energy of a System of Charged Particles** The electric potential energy of a system of charged particles is equal to the work needed to assemble the system with the particles initially at rest and infinitely distant from each other. For two particles at separation \( r \),

\[ U = W = \frac{1}{4\pi\varepsilon_0} \frac{q_1 q_2}{r}. \]  

(24-46)

**Potential of a Charged Conductor** An excess charge placed on a conductor will, in the equilibrium state, be located entirely on the outer surface of the conductor. The charge will distribute itself so that the following occur: (1) The entire conductor, including interior points, is at a uniform potential. (2) At every internal point, the electric field due to the charge cancels the external electric field that otherwise would have been there. (3) The net electric field at every point on the surface is perpendicular to the surface.

**Questions**

1. Figure 24-24 shows eight particles that form a square, with distance \( d \) between adjacent particles. What is the net electric potential at point \( P \) at the center of the square if we take the electric potential to be zero at infinity?

2. Figure 24-25 shows three sets of cross sections of equipotential surfaces in uniform electric fields; all three cover the same size region of space. The electric potential is indicated for each equipotential surface. (a) Rank the arrangements according to the magnitude of the electric field present in the region, greatest first. (b) In which is the electric field directed down the page?

---

**Figure 24-24** Question 1.

**Figure 24-25** Question 2.
3 Figure 24-26 shows four pairs of charged particles. For each pair, let \( V = 0 \) at infinity and consider \( V_{\text{net}} \) at points on the \( x \) axis. For which pairs is there a point at which \( V_{\text{net}} = 0 \) (a) between the particles and (b) to the right of the particles? (c) At such a point is \( E_{\text{net}} \) due to the particles equal to zero? (d) For each pair, are there off-axis points (other than at infinity) where \( V_{\text{net}} = 0 \)?

![Figure 24-26 Questions 3 and 9.](image)

4 Figure 24-27 gives the electric potential \( V \) as a function of \( x \). (a) Rank the five regions according to the magnitude of the \( x \) component of the electric field within them, greatest first. What is the direction of the field along the \( x \) axis in (b) region 2 and (c) region 4?

![Figure 24-27 Question 4.](image)

5 Figure 24-28 shows three paths along which we can move the positively charged sphere \( A \) closer to a positively charged sphere \( B \), which is held fixed in place. (a) Would sphere \( A \) be moved to a higher or lower electric potential? Is the work done (b) by our force and (c) by the electric field due to \( B \) positive, negative, or zero? (d) Rank the paths according to the work our force does, greatest first.

![Figure 24-28 Question 5.](image)

6 Figure 24-29 shows four arrangements of charged particles, all the same distance from the origin. Rank the situations according to the net electric potential at the origin, most positive first. Take the potential to be zero at infinity.

![Figure 24-29 Question 6.](image)

7 Figure 24-30 shows a system of three charged particles. If you move the particle of charge \( +q \) from point \( A \) to point \( D \), you will be moving the following quantities positive, negative, or zero: (a) the change in the electric potential energy of the three-particle system, (b) the work done by the net electric force on the particle you moved (that is, the net force due to the other two particles), and (c) the work done by your force? (d) What are the answers to (a) through (c) if, instead, the particle is moved from \( B \) to \( C \)?

![Figure 24-30 Questions 7 and 8.](image)

8 In the situation of Question 7, is the work done by your force positive, negative, or zero if the particle is moved (a) from \( A \) to \( B \), (b) from \( A \) to \( C \), and (c) from \( B \) to \( D \)? (d) Rank those moves according to the magnitude of the work done by your force, greatest first.

9 Figure 24-26 shows four pairs of charged particles with identical separations. (a) Rank the pairs according to their electric potential energy (that is, the energy of the two-particle system), greatest (most positive) first. (b) For each pair, if the separation between the particles is increased, does the potential energy of the pair increase or decrease?

![Figure 24-31 Question 10.](image)

10 (a) In Fig. 24-31a, what is the potential at point \( P \) due to charge \( Q \) at distance \( R \) from \( P \)? Set \( V = 0 \) at infinity. (b) In Fig. 24-31b, the same charge \( Q \) has been spread uniformly over a circular arc of radius \( R \) and central angle \( 40^\circ \). What is the potential at point \( P \), the center of curvature of the arc? (c) In Fig. 24-31c, the same charge \( Q \) has been spread uniformly over a circle of radius \( R \). What is the potential at point \( P \), the center of the circle? (d) Rank the three situations according to the magnitude of the electric field that is set up at \( P \), greatest first.

![Figure 24-32 Question 11.](image)

11 Figure 24-32 shows a thin, uniformly charged rod and three points at the same distance \( d \) from the rod. Rank the magnitude of the electric potential the rod produces at those three points, greatest first.

![Figure 24-33 Question 12.](image)

12 In Fig. 24-33, a particle is to be released at rest at point \( A \) and then is to be accelerated directly through point \( B \) by an electric field. The potential difference between points \( A \) and \( B \) is 100 V. Which point should be at higher electric potential if the particle is (a) an electron, (b) a proton, and (c) an alpha particle (a nucleus of two protons and two neutrons)? (d) Rank the kinetic energies of the particles at point \( B \), greatest first.
**Problems**

**CHAPTER 24 ELECTRIC POTENTIAL**

**Module 24-1 Electric Potential**

1. **SSM** A particular 12 V car battery can send a total charge of 84 A·h (ampere-hours) through a circuit, from one terminal to the other. (a) How many coulombs of charge does this represent? (Hint: See Eq. 21-3.) (b) If this entire charge undergoes a change in electric potential of 12 V, how much energy is involved?

2. The electric potential difference between the ground and a cloud in a particular thunderstorm is 1.2 × 10^6 V. In the unit electron-volts, what is the magnitude of the change in the electric potential energy of an electron that moves between the ground and the cloud?

3. Suppose that in a lightning flash the potential difference between a cloud and the ground is 1.0 × 10^6 V and the quantity of charge transferred is 30 C. (a) What is the change in energy of that transferred charge? (b) If all the energy released could be used to accelerate a 1000 kg car from rest, what would be its final speed?

**Module 24-2 Equipotential Surfaces and the Electric Field**

4. Two large, parallel, conducting plates are 12 cm apart and have charges of equal magnitude and opposite sign on their facing surfaces. An electric field of 3.9 × 10^{-15} N acts on an electron placed anywhere between the two plates. (Neglect fringing.) (a) Find the electric field at the position of the electron. (b) What is the potential difference between the plates?

5. **SSM** An infinite nonconducting sheet has a surface charge density σ = 0.10 μC/m^2 on one side. How far apart are equipotential surfaces whose potentials differ by 50 V?

6. When an electron moves from A to B along an electric field line in Fig. 24-34, the electric field does 3.94 × 10^{-19} J of work on it. What are the electric potential differences (a) V_B - V_A, (b) V_C - V_A, and (c) V_C - V_B?

7. The electric field in a region of space has the components E_x = E_y = 0 and E_z = (4.00 N/C)x. Point A is on the y axis at y = 3.00 m, and point B is on the x axis at x = 4.00 m. What is the potential difference V_B - V_A?

8. A graph of the x component of the electric field as a function of x in a region of space is shown in Fig. 24-35. The scale of the vertical axis is set by E_0 = 20.0 N/C. The y and z components of the electric field are zero in this region. If the electric potential at the origin is 10 V, (a) what is the electric potential at x = 2.0 m, (b) what is the greatest positive value of the electric potential for points on the x axis for which 0 ≤ x ≤ 6.0 m, and (c) for what value of x is the electric potential zero?

9. An infinite nonconducting sheet has a surface charge density σ = +5.80 pC/m^2. (a) How much work is done by the electric field due to the sheet if a particle of charge q = +1.60 × 10^{-19} C is moved from the sheet to a point P at distance d = 3.56 cm from the sheet? (b) If the electric potential V is defined to be zero on the sheet, what is V at P?

**Module 24-3 Potential Due to a Charged Particle**

10. Two uniformly charged, infinite, nonconducting planes are parallel to a yz plane and positioned at x = -50 cm and x = +50 cm. The charge densities on the planes are -50 nC/m^2 and +25 nC/m^2, respectively. What is the magnitude of the potential difference between the origin and the point on the x axis at x = +80 cm? (Hint: Use Gauss’ law.)

11. A nonconducting sphere has radius R = 2.31 cm and uniformly distributed charge q = +3.50 nC. Take the electric potential at the sphere’s center to be V_0 = 0. What is V at radial distance (a) r = 1.45 cm and (b) r = R. (Hint: See Module 23-6.)

12. As a space shuttle moves through the dilute ionized gas of Earth’s ionosphere, the shuttle’s potential is typically changed by -1.0 V during one revolution. Assuming the shuttle is a sphere of radius 10 m, estimate the amount of charge it collects.

13. What are (a) the charge and (b) the charge density on the surface of a conducting sphere of radius 0.15 m whose potential is 200 V (with V = 0 at infinity)?

14. Consider a particle with charge q = 1.0 μC, point A at distance d_1 = 2.0 m from q, and point B at distance d_2 = 1.0 m. (a) If A and B are diametrically opposite each other, as in Fig. 24-36a, what is the electric potential difference V_A - V_B? (b) What is that electric potential difference if A and B are located as in Fig. 24-36b?

15. **SSM** ILW A spherical drop of water carrying a charge of 30 pC has a potential of 500 V at its surface (with V = 0 at infinity). (a) What is the radius of the drop? (b) If two such drops of the same charge and radius combine to form a single spherical drop, what is the potential at the surface of the new drop?

16. Figure 24-37 shows a rectangular array of charged particles fixed in place, with distance a = 39.0 cm and the charges shown as integer multiples of q_1 = 3.40 pC and q_2 = 6.00 pC. With V = 0 at infinity, what is the electric potential difference between points a and b?
is the net electric potential at the rectangle’s center? (Hint: Thoughtful examination of the arrangement can reduce the calculation.)

**17** In Fig. 24-38, what is the net electric potential at point P due to the four particles if \( V = 0 \) at infinity, \( q = 5.00 \text{ fC} \), and \( d = 4.00 \text{ cm} \)?

**18** Two charged particles are shown in Fig. 24-39a. Particle 1, with charge \( q_1 \), is fixed in place at distance \( d \). Particle 2, with charge \( q_2 \), can be moved along the \( x \) axis. Figure 24-39b gives the net electric potential \( V \) at the origin due to the two particles as a function of the \( x \) coordinate of particle 2. The scale of the \( x \) axis is set by \( x_o = 16.0 \text{ cm} \). The plot has an asymptote of \( V = 5.76 \times 10^{-7} \text{ V} \) as \( x \rightarrow \infty \). What is \( q_2 \) in terms of \( e \)?

**19** In Fig. 24-40, particles with the charges \( q_1 = +5e \) and \( q_2 = -15e \) are fixed in place with a separation of \( d = 24.0 \text{ cm} \). With electric potential defined to be \( V = 0 \) at infinity, what are the finite (a) positive and (b) negative values of \( x \) at which the net electric potential on the \( x \) axis is zero?

**20** Two particles, of charges \( q_1 \) and \( q_2 \), are separated by distance \( d \) in Fig. 24-40. The net electric field due to the particles is zero at \( x = d/4 \). With \( V = 0 \) at infinity, locate (in terms of \( d \) ) any point on the \( x \) axis (other than at infinity) at which the electric potential due to the two particles is zero.

**Module 24-4 Potential Due to an Electric Dipole**

**21** The ammonia molecule \( \text{NH}_3 \) has a permanent electric dipole moment equal to 1.47 D, where 1 D = 1 debye unit = \( 3.34 \times 10^{-30} \text{ C} \cdot \text{m} \). Calculate the electric potential due to an ammonia molecule at a point 52.0 nm away along the axis of the dipole. (Set \( V = 0 \) at infinity.)

**22** In Fig. 24-41a, a particle of elementary charge \( +e \) is initially at coordinate \( z = 20 \text{ nm} \) on the dipole axis (here a \( z \) axis) through an electric dipole, on the positive side of the dipole. (The origin of \( z \) is at the center of the dipole.) The particle is then moved along a circular path around the dipole center until it is at coordinate \( z = -20 \text{ nm} \), on the negative side of the dipole axis. Figure 24-41b gives the work \( W_o \) done by the force moving the particle versus the angle \( \theta \) that locates the particle relative to the positive direction of the \( z \) axis. The scale of the vertical axis is set by \( W_{oo} = 4.0 \times 10^{-30} \text{ J} \). What is the magnitude of the dipole moment?

**Module 24-5 Potential Due to a Continuous Charge Distribution**

**23** (a) Figure 24-42a shows a nonconducting rod of length \( L = 6.00 \text{ cm} \) and uniform linear charge density \( \lambda = +3.68 \text{ pC/cm} \). Assume that the electric potential is defined to be \( V = 0 \) at infinity. What is \( V \) at point \( P \) at distance \( d = 8.00 \text{ cm} \) along the rod’s perpendicular bisector? (b) Figure 24-42b shows an identical rod except that one half is now negatively charged. Both halves have a linear charge density of magnitude 3.68 pC/cm. With \( V = 0 \) at infinity, what is \( V \) at \( P \)?

**24** In Fig. 24-43, a plastic rod having a uniformly distributed charge \( Q = -25.6 \text{ pC} \) has been bent into a circular arc of radius \( R = 3.71 \text{ cm} \) and central angle \( \phi = 120^\circ \). With \( V = 0 \) at infinity, what is the electric potential at \( P \), the center of curvature of the rod?

**25** A plastic rod has been bent into a circle of radius \( R = 8.20 \text{ cm} \). It has a charge \( Q_1 = +4.20 \text{ pC} \) uniformly distributed along one-quarter of its circumference and a charge \( Q_2 = -6Q_1 \) uniformly distributed along the rest of the circumference (Fig. 24-44). With \( V = 0 \) at infinity, what is the electric potential at (a) the center \( C \) of the circle and (b) point \( P \), on the central axis of the circle at distance \( D = 6.71 \text{ cm} \) from the center?

**26** Figure 24-45 shows a thin rod with a uniform charge density of 2.00 \( \mu \text{C/cm} \). Evaluate the electric potential at point \( P \) if \( d = D = L/4.00 \). Assume that the potential is zero at infinity.
27 In Fig. 24-46, three thin plastic rods form quarter-circles with a common center of curvature at the origin. The uniform charges on the three rods are $Q_1 = +30$ nC, $Q_2 = +3.0Q_1$, and $Q_3 = -8.0Q_1$. What is the net electric potential at the origin due to the rods?

28 Figure 24-47 shows a thin plastic rod of length $L = 12.0$ cm and uniform positive charge $Q = 56.1$ fC lying on an $x$ axis. With $V = 0$ at infinity, find the electric potential at point $P_1$ on the axis, at distance $d = 2.50$ cm from the rod.

29 In Fig. 24-48, what is the net electric potential at the origin due to the circular arc of charge $Q_1 = +7.21$ pC and the two particles of charges $Q_2 = 4.00Q_1$ and $Q_3 = -2.00Q_1$? The arc’s center of curvature is at the origin and its radius is $R = 2.00$ m; the angle indicated is $\theta = 20.0^\circ$.

30 The smiling face of Fig. 24-49 consists of three items:

1. a thin rod of charge $-3.0$ $\mu$C that forms a full circle of radius 6.0 cm;
2. a second thin rod of charge 2.0 $\mu$C that forms a circular arc of radius 4.0 cm, subtending an angle of 90° about the center of the full circle;
3. an electric dipole with a dipole moment that is perpendicular to a radial line and has a magnitude of $1.28 \times 10^{-21}$ C·m.

What is the net electric potential at the center?

31 A plastic disk of radius $R = 64.0$ cm is charged on one side with a uniform surface charge density $\sigma = 7.73$ fC/m$^2$, and then three quadrants of the disk are removed. The remaining quadrant is shown in Fig. 24-50. With $V = 0$ at infinity, what is the potential due to the remaining quadrant at point $P$, which is on the central axis of the original disk at distance $D = 25.9$ cm from the original center?

32 A nonuniform linear charge distribution given by $\lambda = bx$, where $b$ is a constant, is located along an $x$ axis from $x = 0$ to $x = 0.20$ m. If $b = 20$ nC/m$^2$ and $V = 0$ at infinity, what is the electric potential at (a) the origin and (b) the point $y = 0.15$ m on the $y$ axis?

33 The thin plastic rod shown in Fig. 24-47 has length $L = 12.0$ cm and a nonuniform linear charge density $\lambda = cx$, where $c = 28.9$ pC/m$^2$. With $V = 0$ at infinity, find the electric potential at point $P_1$ on the axis, at distance $d = 3.00$ cm from one end.

Module 24-6 Calculating the Field from the Potential

34 Two large parallel metal plates are 1.5 cm apart and have charges of equal magnitudes but opposite signs on their facing surfaces. Take the potential of the negative plate to be zero. If the potential halfway between the plates is then $+5.0$ V, what is the electric field in the region between the plates?

35 The electric potential at points in an $xy$ plane is given by $V = (2.0$ V/m$^2)x^2 - (3.0$ V/m$^2)y^2$. In unit-vector notation, what is the electric field at the point (3.0 m, 2.0 m)?

36 The electric potential $V$ in the space between two flat parallel plates 1 and 2 is given (in volts) by $V = 1500x^2$, where $x$ (in meters) is the perpendicular distance from plate 1. At $x = 1.3$ cm, (a) what is the magnitude of the electric field and (b) is the field directed toward or away from plate 1?

37 What is the magnitude of the electric field at the point $(3.00i - 2.00j + 4.00k)$ m if the electric potential in the region is given by $V = 2.00xyz^2$, where $V$ is in volts and coordinates $x$, $y$, and $z$ are in meters?

38 Figure 24-47 shows a thin plastic rod of length $L = 13.5$ cm and uniform charge 43.6 fC. (a) In terms of distance $d$, find an expression for the electric potential at point $P_1$. (b) Next, substitute variable $x$ for $d$ and find an expression for the magnitude of the component $E_x$ of the electric field at $P_1$. (c) What is the direction of $E_x$ relative to the positive direction of the $x$ axis? (d) What is the value of $E_x$ at $P_1$ for $x = 6.20$ cm? (e) From the symmetry in Fig. 24-47, determine $E_y$ at $P_1$.

39 An electron is placed in an $xy$ plane where the electric potential depends on $x$ and $y$ as shown, for the coordinate axes, in Fig. 24-51 (the potential does not depend on $z$). The scale of the vertical axis is set by $V_y = 500$ V. In unit-vector notation, what is the electric force on the electron?

40 The thin plastic rod of length $L = 10.0$ cm in Fig. 24-47 has a nonuniform linear charge density $\lambda = cx$, where $c = 49.9$ pC/m$^2$. (a) With $V = 0$ at infinity, find the electric potential at point $P_2$ on the $y$ axis at $y = D = 3.56$ cm. (b) Find the electric field component $E_x$ at $P_2$. (c) Why cannot the field component $E_y$ at $P_2$ be found using the result of (a)?
Module 24-7 Electric Potential Energy of a System of Charged Particles

41 A particle of charge +7.5 μC is released from rest at the point x = 60 cm on an x axis. The particle begins to move due to the presence of a charge Q that remains fixed at the origin. What is the kinetic energy of the particle at the instant it has moved 40 cm if (a) Q = +20 μC and (b) Q = −20 μC?

42 (a) What is the electric potential energy of two electrons separated by 2.00 nm? (b) If the separation increases, does the potential energy increase or decrease?

43 SSM ILW WWW How much work is required to set up the arrangement of Fig. 24-52 if q = 2.30 pC, a = 64.0 cm, and the particles are initially infinitely far apart and at rest?

44 In Fig. 24-53, seven charged particles are fixed in place to form a square with an edge length of 4.0 cm. How much work must we do to bring a particle of charge +6e initially at rest from an infinite distance to the center of the square?

45 ILW A particle of charge q is fixed at point P, and a second particle of mass m and the same charge q is initially held a distance r₁ from P. The second particle is then released. Determine its speed when it is a distance r₂ from P. Let q = 3.1 μC, m = 20 mg, r₁ = 0.90 mm, and r₂ = 2.5 mm.

46 A charge of −9.0 nC is uniformly distributed around a thin plastic ring lying in a yz plane with the ring center at the origin. A −6.0 pC particle is located on the x axis at x = 3.0 m. For a ring radius of 1.5 m, how much work must an external force do on the particle to move it to the origin?

47 What is the escape speed for an electron initially at rest on the surface of a sphere with a radius of 1.0 cm and a uniformly distributed charge of 1.6 × 10⁻¹⁵ C? That is, what initial speed must the electron have in order to reach an infinite distance from the sphere and have zero kinetic energy when it gets there?

48 A thin, spherical, conducting shell of radius R is mounted on an isolating support and charged to a potential of −125 V. An electron is then fired directly toward the center of the shell, from point P at distance r from the center of the shell (r ≫ R). What initial speed v₀ is needed for the electron to just reach the shell before reversing direction?

49 Two electrons are fixed 2.0 cm apart. Another electron is shot from infinity and stops midway between the two. What is its initial speed?

50 In Fig. 24-54, how much work must we do to bring a particle, of charge Q = +16e and initially at rest, along the dashed line from infinity to the indicated point near two fixed particles of charges q₁ = +4e and q₂ = −q₁/2? Distance d = 1.40 cm, θ₁ = 43°, and θ₂ = 60°.

51 In the rectangle of Fig. 24-55, the sides have lengths 5.0 cm and 15 cm, q₁ = −5.0 μC, and q₂ = +2.0 μC. With V = 0 at infinity, what is the electric potential at (a) corner A and (b) corner B? (c) How much work is required to move a charge q₁ = +3.0 μC from B to A along a diagonal of the rectangle? (d) Does this work increase or decrease the electric potential energy of the three-charge system? Is more, less, or the same work required if q₁ is moved along a path that is (e) inside the rectangle but not on a diagonal and (f) outside the rectangle?

52 Figure 24-56a shows an electron moving along an electric dipole axis toward the negative side of the dipole. The dipole is fixed in place. The electron was initially very far from the dipole, with kinetic energy 100 eV. Figure 24-56b gives the kinetic energy K of the electron versus its distance r from the dipole center. The scale of the horizontal axis is set by r₁ = 0.10 m. What is the magnitude of the dipole moment?

53 Two tiny metal spheres A and B, mass m₁ = 5.00 g and m₂ = 10.0 g, have equal positive charge q = 5.00 μC. The spheres are connected by a massless nonconducting string of length d = 1.00 m, which is much greater than the radii of the spheres. (a) What is the electric potential energy of the system? (b) Suppose you cut the string. At that instant, what is the acceleration of each sphere? (c) A long time after you cut the string, what is the speed of each sphere?

54 A positron (charge +e, mass equal to the electron mass) is moving at 1.0 × 10⁷ m/s in the positive direction of an x axis when, at x = 0, it encounters an electric field directed along the x axis. The electric potential V associated with the field is given in Fig. 24-57. The scale of the vertical axis is set by V₀ = 500.0 V. (a) Does the positron emerge from the field at x = 0 (which means its motion is reversed) or at x = 0.50 m (which means its motion is not reversed)? (b) What is its speed when it emerges?

55 An electron is projected with an initial speed of 3.2 × 10⁸ m/s directly toward a proton that is fixed in place. If the electron is initially a great distance from the proton, at what distance from the proton is the speed of the electron instantaneously equal to twice the initial value?

56 Particle 1 (with a charge of +5.0 μC) and particle 2 (with a charge of +3.0 μC) are fixed in place with separation d = 4.0 cm.
on the $x$ axis shown in Fig. 24-58a. Particle 3 can be moved along the $x$ axis to the right of particle 2. Figure 24-58b gives the electric potential energy $U$ of the three-particle system as a function of the $x$ coordinate of particle 3. The scale of the vertical axis is set by $U_x = 5.0 \text{ J}$. What is the charge of particle 3?

![Figure 24-58 Problem 56.](image)

**Problem 56.**

Identical 50 $\mu$C charges are fixed on an $x$ axis at $x = \pm 3.0 \text{ m}$. A particle of charge $q = -15 \mu$C is then released from rest at a point on the positive part of the $y$ axis. Due to the symmetry of the situation, the particle moves along the $y$ axis and has kinetic energy 1.2 J as it passes through the point $x = 0$, $y = 4.0 \text{ m}$. (a) What is the kinetic energy of the particle as it passes through the origin? (b) At what negative value of $y$ will the particle momentarily stop?

**Problem 58.**

Proton in a well. Figure 24-59 shows electric potential $V$ along an $x$ axis. The scale of the vertical axis is set by $V_1 = 10.0 \text{ V}$. A proton is to be released at $x = 3.5 \text{ cm}$ with initial kinetic energy 4.00 eV. (a) If it is initially moving in the negative direction of the axis, does it reach a turning point (if so, what is the $x$ coordinate of that point) or does it escape from the plotted region (if so, what is its speed at $x = 0$)? (b) If it is initially moving in the positive direction of the axis, does it reach a turning point (if so, what is the $x$ coordinate of that point) or does it escape from the plotted region (if so, what is its speed at $x = 6.0 \text{ cm}$)? What are the (c) magnitude $F$ and (d) direction (positive or negative direction of the $x$ axis) of the electric force on the proton if the proton moves just to the left of $x = 3.0 \text{ cm}$? What are (e) $F$ and (f) the direction if the proton moves just to the right of $x = 5.0 \text{ cm}$?

![Figure 24-59 Problem 58.](image)

**Problem 59.**

In Fig. 24-60, a charged particle (either an electron or a proton) is moving rightward between two parallel charged plates separated by distance $d = 2.00 \text{ mm}$. The plate potentials are $V_1 = -70.0 \text{ V}$ and $V_2 = -50.0 \text{ V}$. The particle is slowing from an initial speed of 90.0 km/s at the left plate. (a) Is the particle an electron or a proton? (b) What is its speed just as it reaches plate 2?

![Figure 24-60 Problem 59.](image)

**Problem 60.**

In Fig. 24-61a, we move an electron from an infinite distance to a point at distance $R = 8.00 \text{ cm}$ from a tiny charged ball. The move requires work $W = 2.16 \times 10^{-13} \text{ J}$ by us. (a) What is the charge $Q$ on the ball? In Fig. 24-61b, the ball has been sliced up and the slices spread out so that an equal amount of charge is at the hour positions on a circular clock face of radius $R = 8.00 \text{ cm}$. Now the electron is brought from an infinite distance to the center of the circle. (b) With that addition of the electron to the system of 12 charged particles, what is the change in the electric potential energy of the system?

![Figure 24-61 Problem 60.](image)

**Problem 61.**

Suppose $N$ electrons can be placed in either of two configurations. In configuration 1, they are all placed on the circumference of a narrow ring of radius $R$ and are uniformly distributed so that the distance between adjacent electrons is the same everywhere. In configuration 2, $N-1$ electrons are uniformly distributed on the ring and one electron is placed in the center of the ring. (a) What is the smallest value of $N$ for which the second configuration is less energetic than the first? (b) For that value of $N$, consider any one circumference electron—call it $e_h$. How many other circumference electrons are closer to $e_h$ than the central electron is?

**Module 24-8 Potential of a Charged Isolated Conductor**

**Problem 62.**

Sphere 1 with radius $R_1$ has positive charge $q$. Sphere 2 with radius $2.00R_1$ is far from sphere 1 and initially uncharged. After the separated spheres are connected with a wire thin enough to retain only negligible charge, (a) is potential $V_1$ of sphere 1 greater than, less than, or equal to potential $V_2$ of sphere 2? What fraction of $q$ ends up on (b) sphere 1 and (c) sphere 2? (d) What is the ratio $\sigma_1/\sigma_2$ of the surface charge densities of the spheres?

**Problem 63.**

Two metal spheres, each of radius 3.0 cm, have a center-to-center separation of 2.0 m. Sphere 1 has charge $+1.0 \times 10^{-5} \text{ C}$; sphere 2 has charge $-3.0 \times 10^{-5} \text{ C}$. Assume that the separation is large enough for us to say that the charge on each sphere is uniformly distributed (the spheres do not affect each other). With $V = 0$ at infinity, calculate (a) the potential at the point halfway between the centers and the potential on the surface of (b) sphere 1 and (c) sphere 2.

**Problem 64.**

A hollow metal sphere has a potential of $+400 \text{ V}$ with respect to ground (defined to be at $V = 0$) and a charge of $5.0 \times 10^{-6} \text{ C}$. Find the electric potential at the center of the sphere.

**Problem 65.**

What is the excess charge on a conducting sphere of radius $r = 0.15 \text{ m}$ if the potential of the sphere is 1500 V and $V = 0$ at infinity?

**Problem 66.**

Two isolated, concentric, conducting spherical shells have radii $R_1 = 0.500 \text{ m}$ and $R_2 = 1.00 \text{ m}$, uniform charges $q_1 = +2.00 \mu\text{C}$ and $q_2 = +1.0 \mu\text{C}$, and negligible thicknesses. What is the magnitude of the electric field $E$ at radial distance (a) $r = 4.00 \text{ m}$, (b) $r = 0.700 \text{ m}$, and (c) $r = 0.200 \text{ m}$? With $V = 0$ at infinity, what is $V$ at (d) $r = 4.00 \text{ m}$, (e) $r = 1.00 \text{ m}$, (f) $r = 0.700 \text{ m}$, (g) $r = 0.500 \text{ m}$, (h) $r = 0.200 \text{ m}$, and (i) $r = 0$? (j) Sketch $E(r)$ and $V(r)$.

**Problem 67.**

A metal sphere of radius 15 cm has a net charge of $3.0 \times 10^{-8} \text{ C}$. (a) What is the electric field at the sphere’s surface? (b) If $V = 0$ at infinity, what is the electric potential at the sphere’s surface? (c) At what distance from the sphere’s surface has the electric potential decreased by 500 V?
Additional Problems

68 Here are the charges and coordinates of two charged particles located in an xy plane: $q_1 = +3.00 \times 10^{-6}$ C, $x = +3.50$ cm, $y = +0.500$ cm and $q_2 = -4.00 \times 10^{-6}$ C, $x = -2.00$ cm, $y = +1.50$ cm. How much work must be done to locate these charges at their given positions, starting from infinite separation?

69 A long, solid, conducting cylinder has a radius of 2.0 cm. The electric field at the surface of the cylinder is 160 N/C, directed radially outward. Let $A$, $B$, and $C$ be points that are 1.0 cm, 2.0 cm, and 5.0 cm, respectively, from the central axis of the cylinder. What are (a) the magnitude of the electric field at $C$ and the electric potential differences (b) $V_B - V_C$ and (c) $V_A - V_B$?

70 The chocolate crumb mystery. This story begins with Problem 60 in Chapter 23. (a) From the answer to part (a) of that problem, find an expression for the electric potential as a function of the radial distance $r$ from the center of the pipe. (The electric potential is zero on the grounded pipe wall.) (b) For the typical volume charge density $\rho = -1.1 \times 10^{-3}$ C/m$^3$, what is the difference in the electric potential between the pipe’s center and its inside wall? (The story continues with Problem 60 in Chapter 25.)

71 Starting from Eq. 24-30, derive an expression for the electric field due to a dipole at a point on the dipole axis.

72 The magnitude $E$ of an electric field depends on the radial distance $r$ according to $E = A/r^2$, where $A$ is a constant with the unit volt–cubic meter. As a multiple of $A$, what is the magnitude of the electric potential difference between $r = 2.00$ m and $r = 3.00$ m?

73 (a) If an isolated conducting sphere 10 cm in radius has a net charge of 4.0 $\mu$C and if $V = 0$ at infinity, what is the potential on the surface of the sphere? (b) Can this situation actually occur, given that the air around the sphere undergoes electrical breakdown when the field exceeds 3.0 MV/m?

74 Three particles, charge $q_1 = +10 \mu$C, $q_2 = -20 \mu$C, and $q_3 = +30 \mu$C, are positioned at the vertices of an isosceles triangle as shown in Fig. 24-62. If $a = 10$ cm and $b = 6.0$ cm, how much work must an external agent do to exchange the positions of (a) $q_1$ and $q_2$ and, instead, (b) $q_1$ and $q_3$?

75 An electric field of approximately 100 V/m is often observed near the surface of the Earth. If this were the field over the entire surface, what would be the electric potential of a point on the surface? (Set $V = 0$ at infinity.)

76 A Gaussian sphere of radius 4.00 cm is centered on a ball that has a radius of 1.00 cm and a uniform charge distribution. The total (net) electric flux through the surface of the Gaussian sphere is $+5.60 \times 10^4$ N·m$^2$/C. What is the electric potential 12.0 cm from the center of the ball?

77 In a Millikan oil-drop experiment (Module 22-6), a uniform electric field of 1.92 $\times 10^5$ N/C is maintained in the region between two plates separated by 1.50 cm. Find the potential difference between the plates.

78 Figure 24-63 shows three circular, nonconducting arcs of radius $R = 8.50$ cm. The charges on the arcs are $q_1 = 4.52$ pC, $q_2 = -2.00q_1$, $q_3 = +3.00q_1$. With $V = 0$ at infinity, what is the net electric potential of the arcs at the common center of curvature?

79 An electron is released from rest on the axis of an electric dipole that has charge $e$ and charge separation $d = 20$ pm and that is fixed in place. The release point is on the positive side of the dipole, at distance $7.0d$ from the dipole center. What is the electron’s speed when it reaches a point $5.0d$ from the dipole center?

80 Figure 24-64 shows a ring of outer radius $R = 13.0$ cm, inner radius $r = 0.200R$, and uniform surface charge density $\sigma = 6.20$ pC/m$^2$. With $V = 0$ at infinity, find the electric potential at point $P$ on the central axis of the ring, at distance $z = 2.00R$ from the center of the ring.

81 Electron in a well. Figure 24-65 shows electric potential $V$ along an x axis. The scale of the vertical axis is set by $V_e = 8.0$ V. An electron is to be released at $x = 4.5$ cm with initial kinetic energy 3.00 eV. (a) If it is initially moving in the negative direction of the axis, does it reach a turning point (if so, what is the x coordinate of that point) or does it escape from the plotted region (if so, what is its speed at $x = 0$)? (b) If it is initially moving in the positive direction of the axis, does it reach a turning point (if so, what is the x coordinate of that point) or does it escape from the plotted region (if so, what is its speed at $x = 7.0$ cm)? What are the (c) magnitude $F$ and (d) direction (positive or negative direction of the x axis) of the electric force on the electron if the electron moves just to the left of $x = 4.0$ cm? What are (e) $F$ and (f) the direction if it moves just to the right of $x = 5.0$ cm?

82 (a) If Earth had a uniform surface charge density of 1.0 electron/m$^2$ (a very artificial assumption), what would its potential be? (Set $V = 0$ at infinity.) What would be the (b) magnitude and (c) direction (radially inward or outward) of the electric field due to Earth just outside its surface?

83 In Fig. 24-66, point $P$ is at distance $d_1 = 4.00$ m from particle 1 ($q_1 = -2e$) and distance $d_2 = 2.00$ m from particle 2 ($q_2 = +2e$), with both particles fixed in place. (a) With $V = 0$ at infinity, what is $V$ at $P$? If we bring a particle of charge $q_3 = +2e$ from infinity to $P$, (b) how much work do we do and (c) what is the potential energy of the three-particle system?

84 A solid conducting sphere of radius 3.0 cm has a charge of 30 nC distributed uniformly over its surface. Let $A$ be a point 1.0 cm from the center of the sphere, $S$ be a point on the surface of the sphere, and $B$ be a point 5.0 cm from the center of the sphere. What are the electric potential differences (a) $V_S - V_B$ and (b) $V_A - V_B$?

85 In Fig. 24-67, we move a particle of charge $+2e$ in from infinity to the x axis. How much work do we do? Distance $D$ is 4.00 m.
86 Figure 24-68 shows a hemisphere with a charge of 4.00 μC distributed uniformly through its volume. The hemisphere lies on an xy plane the way half a grapefruit might lie face down on a kitchen table. Point P is located on the plane, along a radial line from the hemisphere’s center of curvature, at radial distance 15 cm. What is the electric potential at point P due to the hemisphere?

87 SSM Three +0.12 C charges form an equilateral triangle 1.7 m on a side. Using energy supplied at the rate of 0.83 kW, how many days would be required to move one of the charges to the midpoint of the line joining the other two charges?

88 Two charges \( q = \pm 2.0 \, \mu C \) are fixed a distance \( d = 2.0 \, \text{cm} \) apart (Fig. 24-69). (a) With \( V = 0 \) at infinity, what is the electric potential at point \( C \)? (b) You bring a third charge \( q = \pm 2.0 \, \mu C \) from infinity to \( C \). How much work must you do? (c) What is the potential energy \( U \) of the three-charge configuration when the third charge is in place?

89 Initially two electrons are fixed in place with a separation of 2.00 μm. How much work must we do to bring a third electron in from infinity to complete an equilateral triangle?

90 A particle of positive charge \( Q \) is fixed at point \( P \). A second particle of mass \( m \) and negative charge \(-q\) moves at constant speed in a circle of radius \( r_1 \), centered at \( P \). Derive an expression for the work \( W \) that must be done by an external agent on the second particle to increase the radius of the circle of motion to \( r_2 \).

91 Two charged, parallel, flat conducting surfaces are spaced \( d = 1.00 \, \text{cm} \) apart and produce a potential difference \( \Delta V = 625 \, \text{V} \) between them. An electron is projected from one surface directly toward the other. What is the initial speed of the electron if it stops just at the second surface?

92 In Fig. 24-70, point \( P \) is at the center of the rectangle. With \( V = 0 \) at infinity, \( q_1 = 5.00 \, \text{mC} \), \( q_2 = 2.00 \, \text{mC} \), \( q_3 = 3.00 \, \text{mC} \), and \( d = 2.54 \, \text{cm} \), what is the net electric potential at \( P \) due to the six charged particles?

93 SSM A uniform charge of \(+16.0 \, \mu \text{C}\) is on a thin circular ring lying in an \( xy \) plane and centered on the origin. The ring’s radius is 3.00 cm. If point \( A \) is at the origin and point \( B \) is on the \( z \) axis at \( z = 4.00 \, \text{cm} \), what is \( V_B - V_A \)?

94 Consider a particle with charge \( q = 1.50 \times 10^{-8} \, \text{C} \), and take \( V = 0 \) at infinity. (a) What are the shape and dimensions of an equipotential surface having a potential of 30.0 V due to \( q \) alone? (b) Are surfaces whose potentials differ by a constant amount (1.0 V, say) evenly spaced?

95 SSM A thick spherical shell of charge \( Q \) and uniform volume charge density \( \rho \) is bounded by radii \( r_1 \) and \( r_2 > r_1 \). With \( V = 0 \) at infinity, find the electric potential \( V \) as a function of distance \( r \) from the center of the distribution, considering regions (a) \( r > r_2 \), (b) \( r_2 > r > r_1 \), and (c) \( r < r_1 \). (d) Do these solutions agree with each other at \( r = r_2 \) and \( r = r_1 \)? (Hint: See Module 23-6.)

96 A charge \( q \) is distributed uniformly throughout a spherical volume of radius \( R \). Let \( V = 0 \) at infinity. What are (a) \( V \) at radial distance \( r < R \) and (b) the potential difference between points at \( r = R \) and the point at \( r = 0 \)?

97 SSM A solid copper sphere whose radius is 1.0 cm has a very thin surface coating of nickel. Some of the nickel atoms are radioactive, each atom emitting an electron as it decays. Half of these electrons enter the copper sphere, each depositing 100 keV of energy there. The other half of the electrons escape, each carrying away a charge \(-e\). The nickel coating has an activity of \( 3.70 \times 10^8 \) radioactive decays per second. The sphere is hung from a long, non-conducting string and isolated from its surroundings. (a) How long will it take for the potential of the sphere to increase by 1000 V? (b) How long will it take for the temperature of the sphere to increase by 5.0 K due to the energy deposited by the electrons? The heat capacity of the sphere is 14 J/K.

98 In Fig. 24-71, a metal sphere with charge \( q = 5.00 \, \mu \text{C} \) and radius \( r = 3.00 \, \text{cm} \) is concentric with a larger metal sphere with charge \( Q = 15.0 \, \mu \text{C} \) and radius \( R = 6.00 \, \text{cm} \). (a) What is the potential difference between the spheres? If we connect the spheres with a wire, what then is the charge on (b) the smaller sphere and (c) the larger sphere?

99 (a) Using Eq. 24-32, show that the electric field at a point on the central axis of a thin ring (of charge \( q \) and radius \( R \)) and at distance \( z \) from the ring is

\[
E = \frac{1}{4 \pi \varepsilon_0} \frac{q}{\sqrt{z^2 + R^2}}.
\]

(b) From this result, derive an expression for the electric field magnitude \( E \) at points on the ring’s axis; compare your result with the calculation of \( E \) in Module 22-4.

100 An alpha particle (which has two protons) is sent directly toward a target nucleus containing 92 protons. The alpha particle has an initial kinetic energy of 0.48 pJ. What is the least center-to-center distance the alpha particle will be from the target nucleus, assuming the nucleus does not move?

101 In the quark model of fundamental particles, a proton is composed of three quarks: two “up” quarks, each having charge \(+2e/3\), and one “down” quark, having charge \(-e/3\). Suppose that the three quarks are equidistant from one another. Take that separation distance to be \(1.32 \times 10^{-15} \, \text{m}\) and calculate the electric potential energy of the system of (a) only the two up quarks and (b) all three quarks.

102 A charge of \(1.50 \times 10^{-8} \, \text{C}\) lies on an isolated metal sphere of radius 16.0 cm. With \( V = 0 \) at infinity, what is the electric potential at points on the sphere’s surface?

103 In Fig. 24-72, two particles of charges \( q_1 \) and \( q_2 \) are fixed to an \( x \) axis. If a third particle, of charge \(+6.0 \, \mu \text{C}\), is brought from an infinite distance to point \( P \), the three-particle system has the same electric potential energy as the original two-particle system. What is the charge ratio \( q_1/q_2 \)?
CHAPTER 25

Capacitance

25-1 CAPACITANCE

Learning Objectives

After reading this module, you should be able to . . .

25.01 Sketch a schematic diagram of a circuit with a parallel-plate capacitor, a battery, and an open or closed switch.
25.02 In a circuit with a battery, an open switch, and an uncharged capacitor, explain what happens to the conduction electrons when the switch is closed.

25.03 For a capacitor, apply the relationship between the magnitude of charge $q$ on either plate ("the charge on the capacitor"), the potential difference $V$ between the plates ("the potential across the capacitor"), and the capacitance $C$ of the capacitor.

Key Ideas

- A capacitor consists of two isolated conductors (the plates) with charges $+q$ and $-q$. Its capacitance $C$ is defined from
  \[ q = CV, \]
  where $V$ is the potential difference between the plates.
- When a circuit with a battery, an open switch, and an uncharged capacitor is completed by closing the switch, conduction electrons shift, leaving the capacitor plates with opposite charges.

What Is Physics?

One goal of physics is to provide the basic science for practical devices designed by engineers. The focus of this chapter is on one extremely common example—the capacitor, a device in which electrical energy can be stored. For example, the batteries in a camera store energy in the photoflash unit by charging a capacitor. The batteries can supply energy at only a modest rate, too slowly for the photoflash unit to emit a flash of light. However, once the capacitor is charged, it can supply energy at a much greater rate when the photoflash unit is triggered—enough energy to allow the unit to emit a burst of bright light.

The physics of capacitors can be generalized to other devices and to any situation involving electric fields. For example, Earth’s atmospheric electric field is modeled by meteorologists as being produced by a huge spherical capacitor that partially discharges via lightning. The charge that skis collect as they slide along snow can be modeled as being stored in a capacitor that frequently discharges as sparks (which can be seen by nighttime skiers on dry snow).

The first step in our discussion of capacitors is to determine how much charge can be stored. This “how much” is called capacitance.

Capacitance

Figure 25-1 shows some of the many sizes and shapes of capacitors. Figure 25-2 shows the basic elements of any capacitor—two isolated conductors of any

![Figure 25-1](image1.png)

![Figure 25-2](image2.png)
shape. No matter what their geometry, flat or not, we call these conductors plates.

Figure 25-3a shows a less general but more conventional arrangement, called a parallel-plate capacitor, consisting of two parallel conducting plates of area \( A \) separated by a distance \( d \). The symbol we use to represent a capacitor (\( \parallel \)) is based on the structure of a parallel-plate capacitor but is used for capacitors of all geometries. We assume for the time being that no material medium (such as glass or plastic) is present in the region between the plates. In Module 25-5, we shall remove this restriction.

When a capacitor is charged, its plates have charges of equal magnitudes but opposite signs: \( +q \) and \( -q \). However, we refer to the charge of a capacitor as being \( q \), the absolute value of these charges on the plates. (Note that \( q \) is not the net charge on the capacitor, which is zero.)

Because the plates are conductors, they are equipotential surfaces; all points on a plate are at the same electric potential. Moreover, there is a potential difference between the two plates. For historical reasons, we represent the absolute value of this potential difference with \( V \) rather than with the \( \Delta V \) we used in previous notation.

The charge \( q \) and the potential difference \( V \) for a capacitor are proportional to each other; that is,

\[
q = CV. \tag{25-1}
\]

The proportionality constant \( C \) is called the capacitance of the capacitor. Its value depends only on the geometry of the plates and not on their charge or potential difference. The capacitance is a measure of how much charge must be put on the plates to produce a certain potential difference between them: The greater the capacitance, the more charge is required.

The SI unit of capacitance that follows from Eq. 25-1 is the coulomb per volt. This unit occurs so often that it is given a special name, the farad (F):

\[
1 \text{ farad} = 1 \text{ F} = 1 \text{ coulomb per volt} = 1 \text{ C/V}. \tag{25-2}
\]

As you will see, the farad is a very large unit. Submultiples of the farad, such as the microfarad (1 \( \mu \text{F} = 10^{-6} \text{ F} \)) and the picofarad (1 \( \text{pF} = 10^{-12} \text{ F} \)), are more convenient units in practice.

### Charging a Capacitor

One way to charge a capacitor is to place it in an electric circuit with a battery. An electric circuit is a path through which charge can flow. A battery is a device that maintains a certain potential difference between its terminals (points at which charge can enter or leave the battery) by means of internal electrochemical reactions in which electric forces can move internal charge.

In Fig. 25-4a, a battery \( B \), a switch \( S \), an uncharged capacitor \( C \), and interconnecting wires form a circuit. The same circuit is shown in the schematic diagram of Fig. 25-4b, in which the symbols for a battery, a switch, and a capacitor represent those devices. The battery maintains potential difference \( V \) between its terminals. The terminal of higher potential is labeled + and is often called the positive terminal; the terminal of lower potential is labeled – and is often called the negative terminal.
The circuit shown in Figs. 25-4a and b is said to be incomplete because switch S is open; that is, the switch does not electrically connect the wires attached to it. When the switch is closed, electrically connecting those wires, the circuit is complete and charge can then flow through the switch and the wires. As we discussed in Chapter 21, the charge that can flow through a conductor, such as a wire, is that of electrons. When the circuit of Fig. 25-4 is completed, electrons are driven through the wires by an electric field that the battery sets up in the wires. The field drives electrons from capacitor plate h to the positive terminal of the battery; thus, plate h, losing electrons, becomes positively charged. The field drives just as many electrons from the negative terminal of the battery to capacitor plate l; thus, plate l, gaining electrons, becomes negatively charged just as much as plate h, losing electrons, becomes positively charged.

Initially, when the plates are uncharged, the potential difference between them is zero. As the plates become oppositely charged, that potential difference increases until it equals the potential difference V between the terminals of the battery. Then plate h and the positive terminal of the battery are at the same potential, and there is no longer an electric field in the wire between them. Similarly, plate l and the negative terminal reach the same potential, and there is then no electric field in the wire between them. Thus, with the field zero, there is no further drive of electrons. The capacitor is then said to be fully charged, with a potential difference V and charge q that are related by Eq. 25-1.

In this book we assume that during the charging of a capacitor and afterward, charge cannot pass from one plate to the other across the gap separating them. Also, we assume that a capacitor can retain (or store) charge indefinitely, until it is put into a circuit where it can be discharged.

Checkpoint 1

Does the capacitance C of a capacitor increase, decrease, or remain the same (a) when the charge q on it is doubled and (b) when the potential difference V across it is tripled?

25-2 CALCULATING THE CAPACITANCE

Learning Objectives

After reading this module, you should be able to . . .

25.04 Explain how Gauss' law is used to find the capacitance of a parallel-plate capacitor.

25.05 For a parallel-plate capacitor, a cylindrical capacitor, a spherical capacitor, and an isolated sphere, calculate the capacitance.

Key Ideas

- We generally determine the capacitance of a particular capacitor configuration by (1) assuming a charge q to have been placed on the plates, (2) finding the electric field $\vec{E}$ due to this charge, (3) evaluating the potential difference V between the plates, and (4) calculating $C$ from $q = CV$. Some results are the following:
- A parallel-plate capacitor with flat parallel plates of area $A$ and spacing $d$ has capacitance
  $$C = \frac{\varepsilon_0 A}{d}.$$  
- A cylindrical capacitor (two long coaxial cylinders) of length $L$ and radii $a$ and $b$ has capacitance
  $$C = 2\pi \varepsilon_0 \frac{L}{\ln(b/a)}.$$  
- A spherical capacitor with concentric spherical plates of radii $a$ and $b$ has capacitance
  $$C = 4\pi \varepsilon_0 \frac{ab}{b - a}.$$  
- An isolated sphere of radius $R$ has capacitance
  $$C = 4\pi \varepsilon_0 R.$$
Calculating the Capacitance

Our goal here is to calculate the capacitance of a capacitor once we know its geometry. Because we shall consider a number of different geometries, it seems wise to develop a general plan to simplify the work. In brief our plan is as follows: (1) Assume a charge \( q \) on the plates; (2) calculate the electric field \( \vec{E} \) between the plates in terms of this charge, using Gauss’ law; (3) knowing \( \vec{E} \), calculate the potential difference \( V \) between the plates from Eq. 24-18; (4) calculate \( C \) from Eq. 25-1.

Before we start, we can simplify the calculation of both the electric field and the potential difference by making certain assumptions. We discuss each in turn.

Calculating the Electric Field

To relate the electric field \( \vec{E} \) between the plates of a capacitor to the charge \( q \) on either plate, we shall use Gauss’ law:

\[
\varepsilon_0 \oint \vec{E} \cdot d\vec{A} = q. \tag{25-3}
\]

Here \( q \) is the charge enclosed by a Gaussian surface and \( \oint \vec{E} \cdot d\vec{A} \) is the net electric flux through that surface. In all cases that we shall consider, the Gaussian surface will be such that whenever there is an electric flux through it, \( \vec{E} \) will have a uniform magnitude \( E \) and the vectors \( \vec{E} \) and \( d\vec{A} \) will be parallel. Equation 25-3 then reduces to

\[
q = \varepsilon_0 EA \quad \text{(special case of Eq. 25-3),} \tag{25-4}
\]

in which \( A \) is the area of that part of the Gaussian surface through which there is a flux. For convenience, we shall always draw the Gaussian surface in such a way that it completely encloses the charge on the positive plate; see Fig. 25-5 for an example.

Calculating the Potential Difference

In the notation of Chapter 24 (Eq. 24-18), the potential difference between the plates of a capacitor is related to the field \( \vec{E} \) by

\[
V_f - V_i = -\int_{-}^{+} \vec{E} \cdot d\vec{s}, \tag{25-5}
\]

in which the integral is to be evaluated along any path that starts on one plate and ends on the other. We shall always choose a path that follows an electric field line, from the negative plate to the positive plate. For this path, the vectors \( \vec{E} \) and \( d\vec{s} \) will have opposite directions; so the dot product \( \vec{E} \cdot d\vec{s} \) will be equal to \(-E \, ds\). Thus, the right side of Eq. 25-5 will then be positive. Letting \( V \) represent the difference \( V_f - V_i \), we can then recast Eq. 25-5 as

\[
V = \int_{-}^{+} E \, ds \quad \text{(special case of Eq. 25-5),} \tag{25-6}
\]

in which the \(-\) and \(+\) remind us that our path of integration starts on the negative plate and ends on the positive plate.

We are now ready to apply Eqs. 25-4 and 25-6 to some particular cases.

A Parallel-Plate Capacitor

We assume, as Fig. 25-5 suggests, that the plates of our parallel-plate capacitor are so large and so close together that we can neglect the fringing of the electric field.
at the edges of the plates, taking \( \bar{E} \) to be constant throughout the region between the plates.

We draw a Gaussian surface that encloses just the charge \( q \) on the positive plate, as in Fig. 25-5. From Eq. 25-4 we can then write
\[
q = e_0 EA, \tag{25-7}
\]
where \( A \) is the area of the plate.

Equation 25-6 yields
\[
V = \int_0^d E \, ds = E \int_0^d ds = Ed. \tag{25-8}
\]
In Eq. 25-8, \( E \) can be placed outside the integral because it is a constant; the second integral then is simply the plate separation \( d \).

If we now substitute \( q \) from Eq. 25-7 and \( V \) from Eq. 25-8 into the relation \( q = CV \) (Eq. 25-1), we find
\[
C = \frac{e_0 A}{d} \quad \text{(parallel-plate capacitor).} \tag{25-9}
\]
Thus, the capacitance does indeed depend only on geometrical factors—namely, the plate area \( A \) and the plate separation \( d \). Note that \( C \) increases as we increase area \( A \) or decrease separation \( d \).

As an aside, we point out that Eq. 25-9 suggests one of our reasons for writing the electrostatic constant in Coulomb’s law in the form \( 1/4\pi \varepsilon_0 \). If we had not done so, Eq. 25-9—which is used more often in engineering practice than Coulomb’s law—would have been less simple in form. We note further that Eq. 25-9 permits us to express the permittivity constant \( \varepsilon_0 \) in a unit more appropriate for use in problems involving capacitors; namely,
\[
\varepsilon_0 = 8.85 \times 10^{-12} \text{ F/m} = 8.85 \text{ pF/m}. \tag{25-10}
\]
We have previously expressed this constant as
\[
\varepsilon_0 = 8.85 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2. \tag{25-11}
\]

**A Cylindrical Capacitor**

Figure 25-6 shows, in cross section, a cylindrical capacitor of length \( L \) formed by two coaxial cylinders of radii \( a \) and \( b \). We assume that \( L \gg b \) so that we can neglect the fringing of the electric field that occurs at the ends of the cylinders. Each plate contains a charge of magnitude \( q \).

As a Gaussian surface, we choose a cylinder of length \( L \) and radius \( r \), closed by end caps and placed as is shown in Fig. 25-6. It is coaxial with the cylinders and encloses the central cylinder and thus also the charge \( q \) on that cylinder. Equation 25-4 then relates that charge and the field magnitude \( E \) as
\[
q = e_0 EA = e_0 E(2\pi r L),
\]
in which \( 2\pi r L \) is the area of the curved part of the Gaussian surface. There is no flux through the end caps. Solving for \( E \) yields
\[
E = \frac{q}{2\pi \varepsilon_0 r L}. \tag{25-12}
\]
Substitution of this result into Eq. 25-6 yields
\[
V = \int_0^r E \, ds = -\frac{q}{2\pi \varepsilon_0 L} \int_b^a \frac{dr}{r} = \frac{q}{2\pi \varepsilon_0 L} \ln \left( \frac{b}{a} \right), \tag{25-13}
\]
where we have used the fact that here \( ds = -dr \) (we integrated radially inward).
CHAPTER 25  CAPACITANCE

Checkpoint 2

For capacitors charged by the same battery, does the charge stored by the capacitor increase, decrease, or remain the same in each of the following situations? (a) The plate separation of a parallel-plate capacitor is increased. (b) The radius of the inner cylinder of a cylindrical capacitor is increased. (c) The radius of the outer spherical shell of a spherical capacitor is increased.

From the relation $C = q/V$, we then have

$$C = \frac{2\pi\varepsilon_0 L}{\ln(b/a)} \quad \text{(cylindrical capacitor).} \quad (25-14)$$

We see that the capacitance of a cylindrical capacitor, like that of a parallel-plate capacitor, depends only on geometrical factors, in this case the length $L$ and the two radii $b$ and $a$.

A Spherical Capacitor

Figure 25-6 can also serve as a central cross section of a capacitor that consists of two concentric spherical shells, of radii $a$ and $b$. As a Gaussian surface we draw a sphere of radius $r$ concentric with the two shells; then Eq. 25-4 yields

$$q = \varepsilon_0 EA = \varepsilon_0 E(4\pi r^2),$$

in which $4\pi r^2$ is the area of the spherical Gaussian surface. We solve this equation for $E$, obtaining

$$E = \frac{1}{4\pi\varepsilon_0} \frac{q}{r^2}, \quad (25-15)$$

which we recognize as the expression for the electric field due to a uniform spherical charge distribution (Eq. 23-15).

If we substitute this expression into Eq. 25-6, we find

$$V = \int E \, ds = -\frac{q}{4\pi\varepsilon_0} \left[ \frac{a}{b} \right] = \frac{q}{4\pi\varepsilon_0} \left( \frac{1}{a} - \frac{1}{b} \right) = \frac{q}{4\pi\varepsilon_0} \left( \frac{b-a}{ab} \right), \quad (25-16)$$

where again we have substituted $-dr$ for $ds$. If we now substitute Eq. 25-16 into Eq. 25-1 and solve for $C$, we find

$$C = 4\pi\varepsilon_0 \frac{ab}{b-a} \quad \text{(spherical capacitor).} \quad (25-17)$$

An Isolated Sphere

We can assign a capacitance to a single isolated spherical conductor of radius $R$ by assuming that the “missing plate” is a conducting sphere of infinite radius. After all, the field lines that leave the surface of a positively charged isolated conductor must end somewhere; the walls of the room in which the conductor is housed can serve effectively as our sphere of infinite radius.

To find the capacitance of the conductor, we first rewrite Eq. 25-17 as

$$C = 4\pi\varepsilon_0 \frac{a}{1 - a/b}.$$

If we then let $b \to \infty$ and substitute $R$ for $a$, we find

$$C = 4\pi\varepsilon_0 R \quad \text{(isolated sphere).} \quad (25-18)$$

Note that this formula and the others we have derived for capacitance (Eqs. 25-9, 25-14, and 25-17) involve the constant $\varepsilon_0$ multiplied by a quantity that has the dimensions of a length.

✅ Checkpoint 2

For capacitors charged by the same battery, does the charge stored by the capacitor increase, decrease, or remain the same in each of the following situations? (a) The plate separation of a parallel-plate capacitor is increased. (b) The radius of the inner cylinder of a cylindrical capacitor is increased. (c) The radius of the outer spherical shell of a spherical capacitor is increased.
Sample Problem 25.01  Charging the plates in a parallel-plate capacitor

In Fig. 25-7a, switch S is closed to connect the uncharged capacitor of capacitance \( C = 0.25 \, \mu F \) to the battery of potential difference \( V = 12 \, V \). The lower capacitor plate has thickness \( L = 0.50 \, \text{cm} \) and face area \( A = 2.0 \times 10^{-4} \, \text{m}^2 \), and it consists of copper, in which the density of conduction electrons is \( n = 8.49 \times 10^{28} \, \text{electrons/m}^2 \). From what depth \( d \) within the plate (Fig. 25-7b) must electrons move to the plate face as the capacitor becomes charged?

**KEY IDEA**

The charge collected on the plate is related to the capacitance and the potential difference across the capacitor by Eq. 25-1 \( q = CV \).

**Calculations:** Because the lower plate is connected to the negative terminal of the battery, conduction electrons move up to the face of the plate. From Eq. 25-1, the total charge magnitude that collects there is

\[
q = CV = (0.25 \times 10^{-6} \, \text{F})(12 \, \text{V}) = 3.0 \times 10^{-6} \, \text{C}.
\]

Dividing this result by \( e \) gives us the number \( N \) of conduction electrons that come up to the face:

\[
N = \frac{q}{e} = \frac{3.0 \times 10^{-6} \, \text{C}}{1.602 \times 10^{-19} \, \text{C}} = 1.873 \times 10^{13} \, \text{electrons}.
\]

These electrons come from a volume that is the product of the face area \( A \) and the depth \( d \) we seek. Thus, from the density of conduction electrons (number per volume), we can write

\[
n = \frac{N}{Ad},
\]

or

\[
d = \frac{N}{An} = \frac{1.873 \times 10^{13} \, \text{electrons}}{(2.0 \times 10^{-4} \, \text{m}^2)(8.49 \times 10^{28} \, \text{electrons/m}^2)} = 1.1 \times 10^{-12} \, \text{m} = 1.1 \, \text{pm}.
\]

(Answer)

We commonly say that electrons move from the battery to the negative face but, actually, the battery sets up an electric field in the wires and plate such that electrons very close to the plate face move up to the negative face.

---

**25-3  CAPACITORS IN PARALLEL AND IN SERIES**

**Learning Objectives**

After reading this module, you should be able to . . .

- Sketch schematic diagrams for a battery and (a) three capacitors in parallel and (b) three capacitors in series.
- Identify that capacitors in parallel have the same potential difference, which is the same value that their equivalent capacitor has.
- Calculate the equivalent of parallel capacitors.
- Identify that the total charge stored on parallel capacitors is the sum of the charges stored on the individual capacitors.
- Identify that capacitors in series have the same charge, which is the same value that their equivalent capacitor has.
- Calculate the equivalent of series capacitors.
- Identify that the potential applied to capacitors in series is equal to the sum of the potentials across the individual capacitors.

**Key Idea**

The equivalent capacitances \( C_{eq} \) of combinations of individual capacitors connected in parallel and in series can be found from

\[
C_{eq} = \sum_{j=1}^{n} C_j \quad (n \text{ capacitors in parallel})
\]

\[
\frac{1}{C_{eq}} = \sum_{j=1}^{n} \frac{1}{C_j} \quad (n \text{ capacitors in series})
\]

Equivalent capacitances can be used to calculate the capacitances of more complicated series–parallel combinations.
When we analyze a circuit of capacitors in parallel, we can simplify it with this mental replacement:

Capacitors in Parallel and in Series

When there is a combination of capacitors in a circuit, we can sometimes replace that combination with an equivalent capacitor—that is, a single capacitor that has the same capacitance as the actual combination of capacitors. With such a replacement, we can simplify the circuit, affording easier solutions for unknown quantities of the circuit. Here we discuss two basic combinations of capacitors that allow such a replacement.

Capacitors in Parallel

Figure 25-8 (a) Three capacitors connected in parallel to battery B. The battery maintains potential difference \( V \) across its terminals and thus across each capacitor. (b) The equivalent capacitor, with capacitance \( C_{eq} \), replaces the parallel combination.

When a potential difference \( V \) is applied across several capacitors connected in parallel, that potential difference \( V \) is applied across each capacitor. The total charge \( q \) stored on the capacitors is the sum of the charges stored on all the capacitors.

When we analyze a circuit of capacitors in parallel, we can simplify it with this mental replacement:

Capacitors connected in parallel can be replaced with an equivalent capacitor that has the same total charge \( q \) and the same potential difference \( V \) as the actual capacitors.

(You might remember this result with the nonsense word “par-V,” which is close to “party,” to mean “capacitors in parallel have the same \( V \).”) Figure 25-8b shows the equivalent capacitor (with equivalent capacitance \( C_{eq} \)) that has replaced the three capacitors (with actual capacitances \( C_1, C_2, \text{ and } C_3 \)) of Fig. 25-8a.

To derive an expression for \( C_{eq} \) in Fig. 25-8b, we first use Eq. 25-1 to find the charge on each actual capacitor:

\[
q_1 = C_1 V, \quad q_2 = C_2 V, \quad \text{and} \quad q_3 = C_3 V.
\]

The total charge on the parallel combination of Fig. 25-8a is then

\[
q = q_1 + q_2 + q_3 = (C_1 + C_2 + C_3)V.
\]

The equivalent capacitance, with the same total charge \( q \) and applied potential difference \( V \) as the combination, is then

\[
C_{eq} = \frac{q}{V} = C_1 + C_2 + C_3,
\]

a result that we can easily extend to any number \( n \) of capacitors, as

\[
C_{eq} = \sum_{j=1}^{n} C_j \quad (n \text{ capacitors in parallel}). \quad (25-19)
\]

Thus, to find the equivalent capacitance of a parallel combination, we simply add the individual capacitances.

Capacitors in Series

Figure 25-9a shows three capacitors connected in series to battery B. This description has little to do with how the capacitors are drawn. Rather, “in series” means that the capacitors are wired serially, one after the other, and that a potential difference \( V \) is
applied across the two ends of the series. (In Fig. 25-9a, this potential difference \( V \) is maintained by battery B.) The potential differences that then exist across the capacitors in the series produce identical charges \( q \) on them.

When a potential difference \( V \) is applied across several capacitors connected in series, the capacitors have identical charge \( q \). The sum of the potential differences across all the capacitors is equal to the applied potential difference \( V \).

We can explain how the capacitors end up with identical charge by following a chain reaction of events, in which the charging of each capacitor causes the charging of the next capacitor. We start with capacitor 3 and work upward to capacitor 1. When the battery is first connected to the series of capacitors, it produces charge \(-q\) on the bottom plate of capacitor 3. That charge then repels negative charge from the top plate of capacitor 3 (leaving it with charge \(+q\)). The repelled negative charge moves to the bottom plate of capacitor 2 (giving it charge \(-q\)). That charge on the bottom plate of capacitor 2 then repels negative charge from the top plate of capacitor 2 (leaving it with charge \(+q\)) to the bottom plate of capacitor 1 (giving it charge \(-q\)). Finally, the charge on the bottom plate of capacitor 1 helps move negative charge from the top plate of capacitor 1 to the battery, leaving that top plate with charge \(+q\).

Here are two important points about capacitors in series:

1. When charge is shifted from one capacitor to another in a series of capacitors, it can move along only one route, such as from capacitor 3 to capacitor 2 in Fig. 25-9a. If there are additional routes, the capacitors are not in series.

2. The battery directly produces charges on only the two plates to which it is connected (the bottom plate of capacitor 3 and the top plate of capacitor 1 in Fig. 25-9a). Charges that are produced on the other plates are due merely to the shifting of charge already there. For example, in Fig. 25-9a, the part of the circuit enclosed by dashed lines is electrically isolated from the rest of the circuit. Thus, its charge can only be redistributed.

When we analyze a circuit of capacitors in series, we can simplify it with this mental replacement:

Capacitors that are connected in series can be replaced with an equivalent capacitor that has the same charge \( q \) and the same total potential difference \( V \) as the actual series capacitors.

(You might remember this with the nonsense word “seri-q” to mean “capacitors in series have the same \( q \).”) Figure 25-9b shows the equivalent capacitor (with equivalent capacitance \( C_{eq} \)) that has replaced the three actual capacitors (with actual capacitances \( C_1 \), \( C_2 \), and \( C_3 \)) of Fig. 25-9a.

To derive an expression for \( C_{eq} \) in Fig. 25-9b, we first use Eq. 25-1 to find the potential difference of each actual capacitor:

\[
V_1 = \frac{q}{C_1}, \quad V_2 = \frac{q}{C_2}, \quad \text{and} \quad V_3 = \frac{q}{C_3}.
\]

The total potential difference \( V \) due to the battery is the sum

\[
V = V_1 + V_2 + V_3 = q \left( \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} \right).
\]

The equivalent capacitance is then

\[
C_{eq} = \frac{q}{V} = \frac{1}{\frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}},
\]

or

\[
\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}.
\]
We can easily extend this to any number $n$ of capacitors as

$$\frac{1}{C_{eq}} = \sum_{j=1}^{n} \frac{1}{C_j} \quad (n \text{ capacitors in series}). \quad (25-20)$$

Using Eq. 25-20 you can show that the equivalent capacitance of a series of capacitances is always less than the least capacitance in the series.

**Checkpoint 3**

A battery of potential $V$ stores charge $q$ on a combination of two identical capacitors. What are the potential difference across and the charge on either capacitor if the capacitors are (a) in parallel and (b) in series?

---

**Sample Problem 25.02  Capacitors in parallel and in series**

(a) Find the equivalent capacitance for the combination of capacitances shown in Fig. 25-10a, across which potential difference $V$ is applied. Assume

$$C_1 = 12.0 \ \mu F, \quad C_2 = 5.30 \ \mu F, \quad \text{and} \quad C_3 = 4.50 \ \mu F.$$  

**KEY IDEA**

Any capacitors connected in series can be replaced with their equivalent capacitor, and any capacitors connected in parallel can be replaced with their equivalent capacitor. Therefore, we should first check whether any of the capacitors in Fig. 25-10a are in parallel or series.

**Finding equivalent capacitance:** Capacitors 1 and 3 are connected one after the other, but are they in series? No. The potential $V$ that is applied to the capacitors produces charge on the bottom plate of capacitor 3. That charge causes charge to shift from the top plate of capacitor 3. However, note that the shifting charge can move to the bot-

---

**Figure 25-10** (a)–(d) Three capacitors are reduced to one equivalent capacitor. (e)–(i) Working backwards to get the charges.
tom plates of both capacitor 1 and capacitor 2. Because there is more than one route for the shifting charge, capacitor 3 is not in series with capacitor 1 (or capacitor 2). Any time you think you might have two capacitors in series, apply this check about the shifting charge.

Are capacitor 1 and capacitor 2 in parallel? Yes. Their top plates are directly wired together and their bottom plates are directly wired together, and electric potential is applied between the top-plate pair and the bottom-plate pair. Thus, capacitor 1 and capacitor 2 are in parallel, and Eq. 25-19 tells us that their equivalent capacitance $C_{12}$ is

$$C_{12} = C_1 + C_2 = 12.0 \mu F + 5.30 \mu F = 17.3 \mu F.$$ 

In Fig. 25-10b, we have replaced capacitors 1 and 2 with their equivalent capacitor, called capacitor 12 (say “one two” and not “twelve”). (The connections at points A and B are exactly the same in Figs. 25-10a and b.)

Is capacitor 12 in series with capacitor 3? Again applying the test for series capacitances, we see that the charge that shifts from the top plate of capacitor 3 must entirely go to the bottom plate of capacitor 12. Thus, capacitor 12 and capacitor 3 are in series, and we can replace them with their equivalent $C_{123}$ (“one two three”), as shown in Fig. 25-10c. From Eq. 25-20, we have

$$\frac{1}{C_{123}} = \frac{1}{C_{12}} + \frac{1}{C_3} = \frac{1}{17.3 \mu F} + \frac{1}{4.50 \mu F} = 0.280 \mu F^{-1},$$

from which

$$C_{123} = \frac{1}{0.280 \mu F^{-1}} = 3.57 \mu F.$$ (Answer)

**Sample Problem 25.03** One capacitor charging up another capacitor

Capacitor 1, with $C_1 = 3.55 \mu F$, is charged to a potential difference $V_0 = 6.30 \text{ V}$, using a 6.30 V battery. The battery is then removed, and the capacitor is connected as in Fig. 25-11 to an uncharged capacitor 2, with $C_2 = 8.95 \mu F$. When switch S is closed, charge flows between the capacitors. Find the charge on each capacitor when equilibrium is reached.

**KEY IDEAS**

The situation here differs from the previous example because here an applied electric potential is *not* maintained across a combination of capacitors by a battery or some other source. Here, just after switch S is closed, the only applied electric potential is that of capacitor 1 on capacitor 2, and that potential is decreasing. Thus, the capacitors in Fig. 25-11 are not connected *in series*; and although they are drawn parallel, in this situation they are not *in parallel*.

(b) The potential difference applied to the input terminals in Fig. 25-10a is $V = 12.5 \text{ V}$. What is the charge on $C_1$?

**KEY IDEAS**

We now need to work backwards from the equivalent capacitance to get the charge on a particular capacitor. We have two techniques for such “backwards work”: (1) Seri-q: Series capacitors have the same charge as their equivalent capacitor. (2) Par-V: Parallel capacitors have the same potential difference as their equivalent capacitor.

**Working backwards:** To get the charge $q_1$ on capacitor 1, we work backwards to that capacitor, starting with the equivalent capacitor 123. Because the given potential difference $V (= 12.5 \text{ V})$ is applied across the actual combination of three capacitors in Fig. 25-10a, it is also applied across $C_{123}$ in Figs. 25-10a and e. Thus, Eq. 25-1 ($q = CV$) gives us

$$q_{123} = C_{123}V = (3.57 \mu F)(12.5 \text{ V}) = 44.6 \mu C.$$ 

The series capacitors 12 and 3 in Fig. 25-10b each have the same charge as their equivalent capacitor 123 (Fig. 25-10f). Thus, capacitor 12 has charge $q_{12} = q_{123} = 44.6 \mu C$. From Eq. 25-1 and Fig. 25-10g, the potential difference across capacitor 12 must be

$$V_{12} = \frac{q_{12}}{C_{12}} = \frac{44.6 \mu C}{17.3 \mu F} = 2.58 \text{ V}.$$ 

The parallel capacitors 1 and 2 each have the same potential difference as their equivalent capacitor 12 (Fig. 25-10h). Thus, capacitor 1 has potential difference $V_1 = V_{12} = 2.58 \text{ V}$, and, from Eq. 25-1 and Fig. 25-10i, the charge on capacitor 1 must be

$$q_1 = C_1V_1 = (12.0 \mu F)(2.58 \text{ V}) = 31.0 \mu C.$$ (Answer)
Energy Stored in an Electric Field

Work must be done by an external agent to charge a capacitor. We can imagine doing the work ourselves by transferring electrons from one plate to the other, one by one. As the charges build, so does the electric field between the plates, which opposes the continued transfer. So, greater amounts of work are required. Actually, a battery does all this for us, at the expense of its stored chemical energy. We visualize the work as being stored as electric potential energy in the electric field between the plates.
Suppose that, at a given instant, a charge $q'$ has been transferred from one plate of a capacitor to the other. The potential difference $V'$ between the plates at that instant will be $q'/C$. If an extra increment of charge $dq'$ is then transferred, the increment of work required will be, from Eq. 24-6,

$$dW = V'\ dq' = \frac{q'}{C}\ dq'.$$

The work required to bring the total capacitor charge up to a final value $q$ is

$$W = \int dW = \frac{1}{C} \int_0^q q'\ dq' = \frac{q^2}{2C}.$$

This work is stored as potential energy $U$ in the capacitor, so that

$$U = \frac{q^2}{2C} \quad \text{(potential energy).} \quad \text{(25-21)}$$

From Eq. 25-1, we can also write this as

$$U = \frac{1}{2} CV^2 \quad \text{(potential energy).} \quad \text{(25-22)}$$

Equations 25-21 and 25-22 hold no matter what the geometry of the capacitor is.

To gain some physical insight into energy storage, consider two parallel-plate capacitors that are identical except that capacitor 1 has twice the plate separation of capacitor 2. Then capacitor 1 has twice the volume between its plates and also, from Eq. 25-9, half the capacitance of capacitor 2. Equation 25-4 tells us that if both capacitors have the same charge $q$, the electric fields between their plates are identical. And Eq. 25-21 tells us that capacitor 1 has twice the stored potential energy of capacitor 2. Thus, of two otherwise identical capacitors with the same charge and same electric field, the one with twice the volume between its plates has twice the stored potential energy. Arguments like this tend to verify our earlier assumption:

The potential energy of a charged capacitor may be viewed as being stored in the electric field between its plates.

**Explosions in Airborne Dust**

As we discussed in Module 24-8, making contact with certain materials, such as clothing, carpets, and even playground slides, can leave you with a significant electrical potential. You might become painfully aware of that potential if a spark leaps between you and a grounded object, such as a faucet. In many industries involving the production and transport of powder, such as in the cosmetic and food industries, such a spark can be disastrous. Although the powder in bulk may not burn at all, when individual powder grains are airborne and thus surrounded by oxygen, they can burn so fiercely that a cloud of the grains burns as an explosion. Safety engineers cannot eliminate all possible sources of sparks in the powder industries. Instead, they attempt to keep the amount of energy available in the sparks below the threshold value $U_t$ ($\approx 150$ mJ) typically required to ignite airborne grains.

Suppose a person becomes charged by contact with various surfaces as he walks through an airborne powder. We can roughly model the person as a spherical capacitor of radius $R = 1.8$ m. From Eq. 25-18 ($C = 4\pi\varepsilon_0 R$) and Eq. 25-22 ($U = \frac{1}{2} CV^2$), we see that the energy of the capacitor is

$$U = \frac{1}{2} (4\pi\varepsilon_0 R) V^2.$$
From this we see that the threshold energy corresponds to a potential of

\[ V = \sqrt{\frac{2U}{4\pi\varepsilon_0 R}} = \sqrt{\frac{2(150 \times 10^{-7} \text{J})}{4\pi(8.85 \times 10^{-12} \text{C}^2/\text{N} \cdot \text{m}^2)(1.8 \text{m})}} = 3.9 \times 10^4 \text{V}. \]

Safety engineers attempt to keep the potential of the personnel below this level by “bleeding” off the charge through, say, a conducting floor.

### Energy Density

In a parallel-plate capacitor, neglecting fringing, the electric field has the same value at all points between the plates. Thus, the energy density \( u \)— that is, the potential energy per unit volume between the plates—should also be uniform. We can find \( u \) by dividing the total potential energy by the volume \( Ad \) of the space between the plates. Using Eq. 25-22, we obtain

\[ (25-23) \]

\[ u = \frac{U}{Ad} = \frac{CV^2}{2Ad}. \]

With Eq. 25-9 \( (C = \varepsilon_0 A/d) \), this result becomes

\[ (25-24) \]

\[ u = \frac{1}{2} \varepsilon_0 \left( \frac{V}{d} \right)^2. \]

However, from Eq. 24-42 \( (E = -\Delta V/\Delta s) \), \( V/d \) equals the electric field magnitude \( E \); so

\[ (25-25) \]

\[ u = \frac{1}{2} \varepsilon_0 E^2 \quad \text{(energy density)}. \]

Although we derived this result for the special case of an electric field of a parallel-plate capacitor, it holds for any electric field. If an electric field \( E \) exists at any point in space, that site has an electric potential energy with a density (amount per unit volume) given by Eq. 25-25.

### Sample Problem 25.04  Potential energy and energy density of an electric field

An isolated conducting sphere whose radius \( R \) is 6.85 cm has a charge \( q = 1.25 \text{ nC} \).

(a) How much potential energy is stored in the electric field of this charged conductor?

**KEY IDEAS**

1. An isolated sphere has capacitance given by Eq. 25-18 \( C = 4\pi\varepsilon_0 R \).
2. The energy \( U \) stored in a capacitor depends on the capacitor’s charge \( q \) and capacitance \( C \) according to Eq. 25-21 \( (U = q^2/2C) \).

**Calculation:** Substituting \( C = 4\pi\varepsilon_0 R \) into Eq. 25-21 gives us

\[ U = \frac{q^2}{2C} = \frac{q^2}{8\pi\varepsilon_0 R} = \frac{(1.25 \times 10^{-9} \text{C})^2}{(8\pi)(8.85 \times 10^{-12} \text{F/m})(0.0685 \text{m})} = 1.03 \times 10^{-7} \text{J} = 103 \text{nJ}. \]

(Answer)

(b) What is the energy density at the surface of the sphere?

**KEY IDEA**

The density \( u \) of the energy stored in an electric field depends on the magnitude \( E \) of the field, according to Eq. 25-25 \( (u = \frac{1}{2} \varepsilon_0 E^2) \).

**Calculations:** Here we must first find \( E \) at the surface of the sphere, as given by Eq. 23-15:

\[ E = \frac{1}{4\pi\varepsilon_0} \frac{q}{R^2}. \]

The energy density is then

\[ u = \frac{1}{2} \varepsilon_0 E^2 = \frac{q^2}{32\pi^2\varepsilon_0 R^4} = \frac{(1.25 \times 10^{-9} \text{C})^2}{(32\pi^2)(8.85 \times 10^{-12} \text{C}^2/\text{N} \cdot \text{m}^2)(0.0685 \text{m})^4} = 2.54 \times 10^{-5} \text{J/m}^3 = 25.4 \mu\text{J/m}^3. \]

(Answer)
25-5 CAPACITOR WITH A DIELECTRIC

Learning Objectives
After reading this module, you should be able to . . .

25.21 Identify that capacitance is increased if the space between the plates is filled with a dielectric material.
25.22 For a capacitor, calculate the capacitance with and without a dielectric.
25.23 For a region filled with a dielectric material with a given dielectric constant $k$, identify that all electrostatic equations containing the permittivity constant $\varepsilon_0$ are modified by multiplying that constant by the dielectric constant to get $k\varepsilon_0$.
25.24 Name some of the common dielectrics.
25.25 In adding a dielectric to a charged capacitor, distinguish the results for a capacitor (a) connected to a battery and (b) not connected to a battery.
25.26 Distinguish polar dielectrics from nonpolar dielectrics.
25.27 In adding a dielectric to a charged capacitor, explain what happens to the electric field between the plates in terms of what happens to the atoms in the dielectric.

Key Ideas
- If the space between the plates of a capacitor is completely filled with a dielectric material, the capacitance $C$ in vacuum (or, effectively, in air) is multiplied by the material's dielectric constant $k$, which is a number greater than 1.
- In a region that is completely filled by a dielectric, all electrostatic equations containing the permittivity constant $\varepsilon_0$ must be modified by replacing $\varepsilon_0$ with $k\varepsilon_0$.
- When a dielectric material is placed in an external electric field, it develops an internal electric field that is oriented opposite the external field, thus reducing the magnitude of the electric field inside the material.
- When a dielectric material is placed in a capacitor with a fixed amount of charge on the surface, the net electric field between the plates is decreased.

Capacitor with a Dielectric

If you fill the space between the plates of a capacitor with a dielectric, which is an insulating material such as mineral oil or plastic, what happens to the capacitance? Michael Faraday—to whom the whole concept of capacitance is largely due and for whom the SI unit of capacitance is named—first looked into this matter in 1837. Using simple equipment much like that shown in Fig. 25-12, he found that the capacitance increased by a numerical factor $k$, which he called

![Image of the simple electrostatic apparatus used by Faraday.](image)
the dielectric constant of the insulating material. Table 25-1 shows some dielectric materials and their dielectric constants. The dielectric constant of a vacuum is unity by definition. Because air is mostly empty space, its measured dielectric constant is only slightly greater than unity. Even common paper can significantly increase the capacitance of a capacitor, and some materials, such as strontium titanate, can increase the capacitance by more than two orders of magnitude.

Another effect of the introduction of a dielectric is to limit the potential difference that can be applied between the plates to a certain value \( V_{\text{max}} \), called the breakdown potential. If this value is substantially exceeded, the dielectric material will break down and form a conducting path between the plates. Every dielectric material has a characteristic dielectric strength, which is the maximum value of the electric field that it can tolerate without breakdown. A few such values are listed in Table 25-1.

As we discussed just after Eq. 25-18, the capacitance of any capacitor can be written in the form

\[
C = \varepsilon_0 L,
\]

in which \( L \) has the dimension of length. For example, \( L = A/d \) for a parallel-plate capacitor. Faraday’s discovery was that, with a dielectric completely filling the space between the plates, Eq. 25-26 becomes

\[
C = \kappa \varepsilon_0 L = \kappa C_{\text{air}},
\]

where \( C_{\text{air}} \) is the value of the capacitance with only air between the plates. For example, if we fill a capacitor with strontium titanate, with a dielectric constant of 310, we multiply the capacitance by 310.

Figure 25-13 provides some insight into Faraday’s experiments. In Fig. 25-13a the battery ensures that the potential difference \( V \) between the plates will remain constant. When a dielectric slab is inserted between the plates, the charge \( q \) on the plates increases by a factor of \( \kappa \); the additional charge is delivered to the capacitor plates by the battery. In Fig. 25-13b there is no battery, and therefore the charge \( q \) must remain constant when the dielectric slab is inserted; then the potential difference \( V \) between the plates decreases by a factor of \( \kappa \). Both these observations are consistent (through the relation \( q = CV \)) with the increase in capacitance caused by the dielectric.

Comparison of Eqs. 25-26 and 25-27 suggests that the effect of a dielectric can be summed up in more general terms:

\[
\text{In a region completely filled by a dielectric material of dielectric constant } \kappa, \text{ all electrostatic equations containing the permittivity constant } \varepsilon_0 \text{ are to be modified by replacing } \varepsilon_0 \text{ with } \kappa \varepsilon_0.
\]

*Measured at room temperature, except for the water.

For a vacuum, \( \kappa = \text{unity.} \)
Thus, the magnitude of the electric field produced by a point charge inside a dielectric is given by this modified form of Eq. 23-15:

\[ E = \frac{1}{4\pi\kappa\varepsilon_0} \frac{q}{r^2}. \]  

(25-28)

Also, the expression for the electric field just outside an isolated conductor immersed in a dielectric (see Eq. 23-11) becomes

\[ E = \frac{\sigma}{\kappa\varepsilon_0}. \]  

(25-29)

Because \( \kappa \) is always greater than unity, both these equations show that for a fixed distribution of charges, the effect of a dielectric is to weaken the electric field that would otherwise be present.

Sample Problem 25.05 Work and energy when a dielectric is inserted into a capacitor

A parallel-plate capacitor whose capacitance \( C \) is 13.5 pF is charged by a battery to a potential difference \( V = 12.5 \text{ V} \) between its plates. The charging battery is now disconnected, and a porcelain slab \( (\kappa = 6.50) \) is slipped between the plates.

(a) What is the potential energy of the capacitor before the slab is inserted?

**KEY IDEA**

We can relate the potential energy \( U_i \) of the capacitor to the capacitance \( C \) and either the potential \( V \) (with Eq. 25-22) or the charge \( q \) (with Eq. 25-21):

\[ U_i = \frac{1}{2}CV^2 = \frac{q^2}{2C}. \]

**Calculation:** Because we are given the initial potential \( V (= 12.5 \text{ V}) \), we use Eq. 25-22 to find the initial stored energy:

\[ U_i = \frac{1}{2}CV^2 = \frac{1}{2}(13.5 \times 10^{-12} \text{ F})(12.5 \text{ V})^2 \]
\[ = 1.055 \times 10^{-9} \text{ J} = 1055 \text{ pJ} \approx 1100 \text{ pJ}. \]  

(Answer)

(b) What is the potential energy of the capacitor–slab device after the slab is inserted?

**Calculation:**

\[ U_f = \frac{q_i^2}{2\kappa C} = \frac{U_i}{\kappa} = \frac{1055 \text{ pJ}}{6.50} \]
\[ = 162 \text{ pJ} \approx 160 \text{ pJ}. \]  

(Answer)

When the slab is introduced, the potential energy decreases by a factor of \( \kappa \).

The “missing” energy, in principle, would be apparent to the person who introduced the slab. The capacitor would exert a tiny tug on the slab and would do work on it, in amount

\[ W = U_i - U_f = (1055 - 162) \text{ pJ} = 893 \text{ pJ}. \]

If the slab were allowed to slide between the plates with no restraint and if there were no friction, the slab would oscillate back and forth between the plates with a (constant) mechanical energy of 893 pJ, and this system energy would transfer back and forth between kinetic energy of the moving slab and potential energy stored in the electric field.

Dielectrics: An Atomic View

What happens, in atomic and molecular terms, when we put a dielectric in an electric field? There are two possibilities, depending on the type of molecule:

1. Polar dielectrics. The molecules of some dielectrics, like water, have permanent electric dipole moments. In such materials (called polar dielectrics), the
electric dipoles tend to line up with an external electric field as in Fig. 25-14. Because the molecules are continuously jostling each other as a result of their random thermal motion, this alignment is not complete, but it becomes more complete as the magnitude of the applied field is increased (or as the temperature, and thus the jostling, are decreased). The alignment of the electric dipoles produces an electric field that is directed opposite the applied field and is smaller in magnitude.

2. Nonpolar dielectrics. Regardless of whether they have permanent electric dipole moments, molecules acquire dipole moments by induction when placed in an external electric field. In Module 24-4 (see Fig. 24-14), we saw that this occurs because the external field tends to “stretch” the molecules, slightly separating the centers of negative and positive charge.

Figure 25-15a shows a nonpolar dielectric slab with no external electric field applied. In Fig. 25-15b, an electric field \( \vec{E}_0 \) is applied via a capacitor, whose plates are charged as shown. The result is a slight separation of the centers of the positive and negative charge distributions within the slab, producing positive charge on one face of the slab (due to the positive ends of dipoles there) and negative charge on the opposite face (due to the negative ends of dipoles there). The slab as a whole remains electrically neutral and—within the slab—there is no excess charge in any volume element.

Figure 25-15c shows that the induced surface charges on the faces produce an electric field \( \vec{E}' \) in the direction opposite that of the applied electric field \( \vec{E}_0 \). The resultant field \( \vec{E} \) inside the dielectric (the vector sum of fields \( \vec{E}_0 \) and \( \vec{E}' \)) has the direction of \( \vec{E}_0 \) but is smaller in magnitude.

Both the field \( \vec{E}' \) produced by the surface charges in Fig. 25-15c and the electric field produced by the permanent electric dipoles in Fig. 25-14 act in the same way—they oppose the applied field \( \vec{E} \). Thus, the effect of both polar and nonpolar dielectrics is to weaken any applied field within them, as between the plates of a capacitor.
In our discussion of Gauss’ law in Chapter 23, we assumed that the charges existed in a vacuum. Here we shall see how to modify and generalize that law if dielectric materials, such as those listed in Table 25-1, are present. Figure 25-16 shows a parallel-plate capacitor of plate area \( A \), both with and without a dielectric. We assume that the charge \( q \) on the plates is the same in both situations. Note that the field between the plates induces charges on the faces of the dielectric by one of the methods described in Module 25-5.

For the situation of Fig. 25-16a, without a dielectric, we can find the electric field \( E_0 \) between the plates as we did in Fig. 25-5: We enclose the charge \( +q \) on the top plate with a Gaussian surface and then apply Gauss’ law. Letting \( E_0 \) represent the magnitude of the field, we find

\[
e_0 \oint E \cdot d\mathbf{A} = e_0 EA = q, \tag{25-30}
\]

or

\[
E_0 = \frac{q}{e_0 A}. \tag{25-31}
\]

In Fig. 25-16b, with the dielectric in place, we can find the electric field between the plates (and within the dielectric) by using the same Gaussian surface. However, now the surface encloses two types of charge: It still encloses charge \( +q \) on the top plate, but it now also encloses the induced charge \( -q' \) on the top face of the dielectric. The charge on the conducting plate is said to be free charge because it can move if we change the electric potential of the plate; the induced charge on the surface of the dielectric is not free charge because it cannot move from that surface.

\[
e_0 \oint \kappa E \cdot d\mathbf{A} = q, \tag{25-30}
\]

where \( q \) is the free charge. Any induced surface charge is accounted for by including the dielectric constant \( \kappa \) inside the integral.

---

**Learning Objectives**

*After reading this module, you should be able to…*

**25.28** In a capacitor with a dielectric, distinguish free charge from induced charge.

**25.29** When a dielectric partially or fully fills the space in a capacitor, find the free charge, the induced charge, the electric field between the plates (if there is a gap, there is more than one field value), and the potential between the plates.

---

**Key Ideas**

- Inserting a dielectric into a capacitor causes induced charge to appear on the faces of the dielectric and weakens the electric field between the plates.
- The induced charge is less than the free charge on the plates.
- When a dielectric is present, Gauss’ law may be generalized to

\[
e_0 \oint \kappa E \cdot d\mathbf{A} = q, \tag{25-30}
\]

where \( q \) is the free charge. Any induced surface charge is accounted for by including the dielectric constant \( \kappa \) inside the integral.
The net charge enclosed by the Gaussian surface in Fig. 25-16b is \( q - q' \), so Gauss’ law now gives

\[
\varepsilon_0 \oint \vec{E} \cdot d\vec{A} = \varepsilon_0 EA = q - q',
\]

(25-32)

or

\[
E = \frac{q - q'}{\varepsilon_0 A}.
\]

(25-33)

The effect of the dielectric is to weaken the original field \( E_0 \) by a factor of \( \kappa \); so we may write

\[
E = \frac{E_0}{\kappa} = \frac{q}{\kappa \varepsilon_0 A}.
\]

(25-34)

Comparison of Eqs. 25-33 and 25-34 shows that

\[
q - q' = \frac{q}{\kappa}.
\]

(25-35)

Equation 25-35 shows correctly that the magnitude \( q' \) of the induced surface charge is less than that of the free charge \( q \) and is zero if no dielectric is present (because then \( \kappa = 1 \) in Eq. 25-35).

By substituting for \( q - q' \) from Eq. 25-35 in Eq. 25-32, we can write Gauss’ law in the form

\[
\varepsilon_0 \oint \kappa \vec{E} \cdot d\vec{A} = q \quad \text{(Gauss’ law with dielectric).}
\]

(25-36)

This equation, although derived for a parallel-plate capacitor, is true generally and is the most general form in which Gauss’ law can be written. Note:

1. The flux integral now involves \( \kappa \vec{E} \), not just \( \vec{E} \). (The vector \( \varepsilon_0 \kappa \vec{E} \) is sometimes called the electric displacement \( \vec{D} \), so that Eq. 25-36 can be written in the form \( \oint \vec{D} \cdot d\vec{A} = q \).)

2. The charge \( q \) enclosed by the Gaussian surface is now taken to be the free charge only. The induced surface charge is deliberately ignored on the right side of Eq. 25-36, having been taken fully into account by introducing the dielectric constant \( \kappa \) on the left side.

3. Equation 25-36 differs from Eq. 23-7, our original statement of Gauss’ law, only in that \( \varepsilon_0 \) in the latter equation has been replaced by \( \kappa \varepsilon_0 \). We keep \( \kappa \) inside the integral of Eq. 25-36 to allow for cases in which \( \kappa \) is not constant over the entire Gaussian surface.

---

**Sample Problem 25.06  Dielectric partially filling the gap in a capacitor**

Figure 25-17 shows a parallel-plate capacitor of plate area \( A \) and plate separation \( d \). A potential difference \( V_0 \) is applied between the plates by connecting a battery between them. The battery is then disconnected, and a dielectric slab of thickness \( b \) and dielectric constant \( \kappa \) is placed between the plates as shown. Assume \( A = 115 \text{ cm}^2 \), \( d = 1.24 \text{ cm} \), \( V_0 = 85.5 \text{ V} \), \( b = 0.780 \text{ cm} \), and \( \kappa = 2.61 \).

(a) What is the capacitance \( C_0 \) before the dielectric slab is inserted?
**Calculation:** From Eq. 25-9 we have

\[
C_0 = \frac{\varepsilon_0 A}{d} = \frac{(8.85 \times 10^{-12} \text{ F/m})(115 \times 10^{-4} \text{ m}^2)}{1.24 \times 10^{-2} \text{ m}} = 8.21 \times 10^{-12} \text{ F} = 8.21 \text{ pF}. \quad \text{(Answer)}
\]

(b) What free charge appears on the plates?

**Calculation:** From Eq. 25-1,

\[
q = C_0 V_0 = (8.21 \times 10^{-12} \text{ F})(85.5 \text{ V}) = 7.02 \times 10^{-10} \text{ C} = 702 \text{ pC}. \quad \text{(Answer)}
\]

Because the battery was disconnected before the slab was inserted, the free charge is unchanged.

(c) What is the electric field \( E_0 \) in the gaps between the plates and the dielectric slab?

**KEY IDEA**

We need to apply Gauss’ law, in the form of Eq. 25-36, to Gaussian surface I in Fig. 25-17.

**Calculations:** That surface passes through the gap, and so it encloses only the free charge on the upper capacitor plate. Electric field pierces only the bottom of the Gaussian surface. Because there the area vector \( d\vec{A} \) and the field vector \( \vec{E}_0 \) are both directed downward, the dot product in Eq. 25-36 becomes

\[
\vec{E}_0 \cdot d\vec{A} = E_0 \, dA \cos 0^\circ = E_0 \, dA.
\]

Equation 25-36 then becomes

\[
\varepsilon_0 \kappa E_0 \int dA = q.
\]

The integration now simply gives the surface area \( A \) of the plate. Thus, we obtain

\[
\varepsilon_0 \kappa E_0 A = q,
\]

or

\[
E_0 = \frac{q}{\varepsilon_0 \kappa A}.
\]

We must put \( \kappa = 1 \) here because Gaussian surface I does not pass through the dielectric. Thus, we have

\[
E_0 = \frac{q}{\varepsilon_0 \kappa A} = \frac{7.02 \times 10^{-10} \text{ C}}{(8.85 \times 10^{-12} \text{ F/m})(1)(115 \times 10^{-4} \text{ m}^2)} = 6900 \text{ V/m} = 6.90 \text{ kV/m}. \quad \text{(Answer)}
\]

Note that the value of \( E_0 \) does not change when the slab is introduced because the amount of charge enclosed by Gaussian surface I in Fig. 25-17 does not change.

(d) What is the electric field \( E_1 \) in the dielectric slab?

**KEY IDEA**

Now we apply Gauss’ law in the form of Eq. 25-36 to Gaussian surface II in Fig. 25-17.

**Calculations:** Only the free charge \(-q\) is in Eq. 25-36, so

\[
\varepsilon_0 \oint \kappa \vec{E}_1 \cdot d\vec{A} = -\varepsilon_0 \kappa E_1 A = -q. \quad \text{(25-37)}
\]

The first minus sign in this equation comes from the dot product \( \vec{E}_1 \cdot d\vec{A} \) along the top of the Gaussian surface because now the field vector \( \vec{E}_1 \) is directed downward and the area vector \( d\vec{A} \) (which, as always, points outward from the interior of a closed Gaussian surface) is directed upward. With 180° between the vectors, the dot product is negative. Now \( \kappa = 2.61 \). Thus, Eq. 25-37 gives us

\[
E_1 = \frac{q}{\varepsilon_0 \kappa A} = \frac{\frac{6.90 \text{ kV/m}}{2.61}} = 2.64 \text{ kV/m}. \quad \text{(Answer)}
\]

(e) What is the potential difference \( V \) between the plates after the slab has been introduced?

**KEY IDEA**

We find \( V \) by integrating along a straight line directly from the bottom plate to the top plate.

**Calculation:** Within the dielectric, the path length is \( b \) and the electric field is \( E_1 \). Within the two gaps above and below the dielectric, the total path length is \( d - b \) and the electric field is \( E_0 \). Equation 25-6 then yields

\[
V = \int_{-b}^{+} E \, ds = E_0(d - b) + E_1 b
\]

\[
= (6900 \text{ V/m})(0.0124 \text{ m} - 0.00780 \text{ m})
\]

\[
+ (2640 \text{ V/m})(0.00780 \text{ m})
\]

\[
= 52.3 \text{ V}. \quad \text{(Answer)}
\]

This is less than the original potential difference of 85.5 V.

(f) What is the capacitance with the slab in place?

**KEY IDEA**

The capacitance \( C \) is related to \( q \) and \( V \) via Eq. 25-1.

**Calculation:** Taking \( q \) from (b) and \( V \) from (e), we have

\[
C = \frac{q}{V} = \frac{7.02 \times 10^{-10} \text{ C}}{52.3 \text{ V}} = 1.34 \times 10^{-11} \text{ F} = 13.4 \text{ pF}. \quad \text{(Answer)}
\]

This is greater than the original capacitance of 8.21 pF.
Review & Summary

Capacitor; Capacitance  A capacitor consists of two isolated conductors (the plates) with charges \( +q \) and \( -q \). Its capacitance \( C \) is defined from

\[
q = CV,
\]
where \( V \) is the potential difference between the plates.

Determining Capacitance  We generally determine the capacitance of a particular capacitor configuration by (1) assuming a charge \( q \) to have been placed on the plates, (2) finding the electric field \( E \) due to this charge, (3) evaluating the potential difference \( V \), and (4) calculating \( C \) from Eq. 25-1. Some specific results are the following:

A parallel-plate capacitor with flat parallel plates of area \( A \) and spacing \( d \) has capacitance

\[
C = \frac{\varepsilon_0 A}{d}.
\]

A cylindrical capacitor (two long coaxial cylinders) of length \( L \) and radii \( a \) and \( b \) has capacitance

\[
C = 2\pi\varepsilon_0 \frac{L}{\ln(b/a)}.
\]

A spherical capacitor with concentric spherical plates of radii \( a \) and \( b \) has capacitance

\[
C = \frac{4\pi\varepsilon_0 ab}{b - a}.
\]

An isolated sphere of radius \( R \) has capacitance

\[
C = 4\pi\varepsilon_0 R.
\]

Capacitors in Parallel and in Series  The equivalent capacitances \( C_{eq} \) of combinations of individual capacitors connected in parallel and in series can be found from

\[
C_{eq} = \sum_{i=1}^{n} C_i \quad \text{(n capacitors in parallel)}
\]

\[
\frac{1}{C_{eq}} = \sum_{i=1}^{n} \frac{1}{C_i} \quad \text{(n capacitors in series)}.
\]

Questions

1  Figure 25-18 shows plots of charge versus potential difference for three parallel-plate capacitors that have the plate areas and separations given in the table. Which plot goes with which capacitor?

2  What is \( C_{eq} \) of three capacitors, each of capacitance \( C \), if they are connected to a battery (a) in series with one another and (b) in parallel? (c) In which arrangement is there more charge on the equivalent capacitance?

3  (a) In Fig. 25-19a, are capacitors 1 and 3 in series? (b) In the same

![Figure 25-18 Question 1](image1)

![Figure 25-19 Question 3](image2)
figure, are capacitors 1 and 2 in parallel? (c) Rank the equivalent capacitances of the four circuits shown in Fig. 25-19, greatest first.

4 Figure 25-20 shows three circuits, each consisting of a switch and two capacitors, initially charged as indicated (top plate positive). After the switches have been closed, in which circuit (if any) will the charge on the left-hand capacitor (a) increase, (b) decrease, and (c) remain the same?

![Figure 25-20](image)

Figure 25-20 Question 4.

5 Initially, a single capacitance \( C_1 \) is wired to a battery. Then capacitance \( C_2 \) is added in parallel. Are (a) the potential difference across \( C_1 \) and (b) the charge \( q_1 \) on \( C_1 \) now more than, less than, or the same as previously? (c) Is the equivalent capacitance \( C_{eq} \) of \( C_1 \) and \( C_2 \) more than, less than, or equal to \( C_1 \)? (d) Is the charge stored on \( C_1 \) and \( C_2 \) together more than, less than, or equal to the charge stored previously on \( C_1 \)?

6 Repeat Question 5 for \( C_1 \) added in series rather than in parallel.

7 For each circuit in Fig. 25-21, are the capacitors connected in series, in parallel, or in neither mode?

![Figure 25-21](image)

Figure 25-21 Question 7.

8 Figure 25-22 shows an open switch, a battery of potential difference \( V \), a current-measuring meter A, and three identical uncharged capacitors of capacitance \( C \). When the switch is closed and the circuit reaches equilibrium, what are (a) the potential difference across each capacitor and (b) the charge on the left plate of each capacitor? (c) During charging, what net charge passes through the meter?

![Figure 25-22](image)

Figure 25-22 Question 8.

9 A parallel-plate capacitor is connected to a battery of electric potential difference \( V \). If the plate separation is decreased, do the following quantities increase, decrease, or remain the same: (a) the capacitor’s capacitance, (b) the potential difference across the capacitor, (c) the charge on the capacitor, (d) the energy stored by the capacitor, (e) the magnitude of the electric field between the plates, and (f) the energy density of that electric field?

10 When a dielectric slab is inserted between the plates of one of the two identical capacitors in Fig. 25-23, do the following properties of that capacitor increase, decrease, or remain the same: (a) capacitance, (b) charge, (c) potential difference, and (d) potential energy? (e) How about the same properties of the other capacitor?

11 You are to connect capacitances \( C_1 \) and \( C_2 \), with \( C_1 > C_2 \), to a battery, first individually, then in series, and then in parallel. Rank those arrangements according to the amount of charge stored, greatest first.
electrons move to the plate face (area \( A \)). In Fig. 25-26, the depth \( d \) from which the electrons come in the plate in a particular capacitor is plotted against a range of values for the potential difference \( V \) of the battery. The density of conduction electrons in the copper plates is \( 8.49 \times 10^{28} \) electrons/m\(^2\). The vertical scale is set by \( d = 1.00 \) pm, and the horizontal scale is set by \( V = 110 \) V.

Problem 7

In Fig. 25-26, the depth \( d \) from which the electrons come in the plate in a particular capacitor is plotted against a range of values for the potential difference \( V \) of the battery.

Problem 8

How many 1.00 \( \mu \)F capacitors must be connected in parallel to store a charge of 1.00 C with a potential of 110 V across the capacitors?

Problem 9

Each of the uncharged capacitors in Fig. 25-27 has a capacitance of 25.0 \( \mu \)F. A potential difference of \( V = 4200 \) V is established when the switch is closed. How many coulombs of charge then pass through meter A?

Problem 10

In Fig. 25-28, find the equivalent capacitance of the combination. Assume that \( C_1 \) is 10.0 \( \mu \)F, \( C_2 \) is 5.00 \( \mu \)F, and \( C_3 \) is 4.00 \( \mu \)F.

Problem 11

In Fig. 25-29, find the equivalent capacitance of the combination. Assume that \( C_1 \) is 10.0 \( \mu \)F, \( C_2 \) is 5.00 \( \mu \)F, and \( C_3 \) is 4.00 \( \mu \)F.

Problem 12

Two parallel-plate capacitors, 6.0 \( \mu \)F each, are connected in parallel to a 10 V battery. One of the capacitors is then squeezed so that its plate separation is 50.0% of its initial value. Because of the squeezing, (a) how much additional charge is transferred to the capacitors by the battery and (b) what is the increase in the total charge stored on the capacitors?

Problem 13

A 100 pF capacitor is charged to a potential difference of 50 V, and the charging battery is disconnected. The capacitor is then connected in parallel with a second (initially uncharged) capacitor. If the potential difference across the first capacitor drops to 35 V, what is the capacitance of this second capacitor?

Problem 14

In Fig. 25-30, the battery has a potential difference of \( V = 10.0 \) V and the five capacitors each have a capacitance of 10.0 \( \mu \)F. What is the charge on (a) capacitor 1 and (b) capacitor 2?

Problem 15

In Fig. 25-31, a 20.0 V battery is connected across capacitors \( C_1 = C_2 = 3.00 \mu \)F and \( C_3 = C_4 = 2.00 \mu \)F. What are (a) the equivalent capacitance \( C_{eq} \) of the capacitors and (b) the charge stored by \( C_{eq} \)? What are (c) \( V_1 \) and (d) \( q_1 \) of capacitor 1, (e) \( V_2 \) and (f) \( q_2 \) of capacitor 2, and (g) \( V_3 \) and (h) \( q_3 \) of capacitor 3?

Problem 16

Plot 1 in Fig. 25-32 gives the charge \( q \) that can be stored on capacitor 1 versus the electric potential \( V \) set up across it. The vertical scale is set by \( q_1 = 16.0 \mu \)C, and the horizontal scale is set by \( V_1 = 2.0 \) V. Plots 2 and 3 are similar plots for capacitors 2 and 3, respectively. Figure 25-32b shows a circuit with those three capacitors and a 6.0 V battery. What is the charge stored on capacitor 2 in that circuit?

Problem 17

In Fig. 25-29, a potential difference of \( V = 100.0 \) V is applied across a capacitor arrangement with capacitances \( C_1 = 10.0 \mu \)F, \( C_2 = 5.00 \mu \)F, and \( C_3 = 4.00 \mu \)F. If capacitor 3 undergoes electrical breakdown so that it becomes equivalent to conducting wire, what is the increase in (a) the charge on capacitor 1 and (b) the potential difference across capacitor 1?

Problem 18

Figure 25-33 shows a circuit section of four air-filled capacitors that is connected to a larger circuit. The graph below the section shows the electric potential \( V(x) \) as a function of position \( x \) along the lower part of the section, through capacitor 4. Similarly, the graph above the section shows the electric potential \( V(x) \) as a function of position \( x \) along the upper part of the section, through capacitors 1, 2, and 3.
Capacitor 3 has a capacitance of 0.80 μF. What are the capacitances of (a) capacitor 1 and (b) capacitor 2?

In Fig. 25-34, the battery has potential difference $V = 9.0$ V, $C_3 = 3.0 \, \mu F$, $C_4 = 4.0 \, \mu F$, and all the capacitors are initially uncharged. When switch S is closed, a total charge of 12 μC passes through point $a$ and a total charge of 8.0 μC passes through point $b$. What are (a) $C_1$ and (b) $C_2$?

Figure 25-35 shows a variable “gap” capacitor for manual tuning. Alternate plates are connected together; one group of plates is fixed in position, and the other group is capable of rotation. Consider a capacitor of $n = 8$ plates of alternating polarity, each plate having area $A = 1.25 \, \text{cm}^2$ and separated from adjacent plates by distance $d = 3.40 \, \text{mm}$. What is the maximum capacitance of the device?

In Fig. 25-36, the capacitances are $C_1 = 1.0 \, \mu F$ and $C_2 = 3.0 \, \mu F$, and both capacitors are charged to a potential difference of $V = 100 \, \text{V}$ but with opposite polarity as shown. Switches $S_1$ and $S_2$ are now closed. (a) What is now the potential difference between points $a$ and $b$? What now is the charge on capacitor (b) 1 and (c) 2?

In Fig. 25-37, $V = 10 \, \text{V}$, $C_1 = 10 \, \mu F$, and $C_2 = C_3 = 20 \, \mu F$. Switch S is first thrown to the left side until capacitor 1 reaches equilibrium. Then the switch is thrown to the right. When equilibrium is again reached, how much charge is on capacitor 1?

The capacitors in Fig. 25-38 are initially uncharged. The capacitances are $C_1 = 4.0 \, \mu F$, $C_2 = 8.0 \, \mu F$, and $C_3 = 12 \, \mu F$, and the battery’s potential difference is $V = 12 \, \text{V}$. When switch S is closed, how many electrons travel through (a) point $a$, (b) point $b$, (c) point $c$, and (d) point $d$? In the figure, do the electrons travel up or down through (e) point $b$ and (f) point $c$?

Figure 25-39 represents two air-filled cylindrical capacitors connected in series across a battery with potential $V = 10 \, \text{V}$. Capacitor 1 has an inner plate radius of 5.0 mm, an outer plate radius of 1.5 cm, and a length of 5.0 cm. Capacitor 2 has an inner plate radius of 2.5 mm, an outer plate radius of 1.0 cm, and a length of 9.0 cm. The outer plate of capacitor 2 is a conducting organic membrane that can be stretched, and the capacitor can be inflated to increase the plate separation. If the outer plate radius is increased to 2.5 cm by inflation, (a) how many electrons move through point $P$ and (b) do they move toward or away from the battery?

In Fig. 25-40, two parallel-plate capacitors (with air between the plates) are connected to a battery. Capacitor 1 has a plate area of 1.5 cm$^2$ and an electric field (between its plates) of magnitude 2000 V/m. Capacitor 2 has a plate area of 0.70 cm$^2$ and an electric field of magnitude 1500 V/m. What is the total charge on the two capacitors?

Capacitor 3 in Fig. 25-41a is a variable capacitor (its capacitance $C_3$ can be varied). Figure 25-41b gives the electric potential $V_1$ across capacitor 1 versus $C_3$. The horizontal scale is set by $C_3 = 12.0 \, \mu F$. Electric potential $V_1$ approaches an asymptote of 10 V as $C_3 \to \infty$. What are (a) the electric potential $V$ across the battery, (b) $C_1$, and (c) $C_2$?

Figure 25-42 shows a 12.0 V battery and four uncharged capacitors of capacitances $C_1 = 1.00 \, \mu F$, $C_2 = 2.00 \, \mu F$, $C_3 = 3.00 \, \mu F$, and $C_4 = 4.00 \, \mu F$. If only switch $S_1$ is closed, what is the charge on (a) capacitor 1, (b) capacitor 2, (c) capacitor 3, and (d) capacitor 4? If both switches are closed, what is the charge on (e) capacitor 1, (f) capacitor 2, (g) capacitor 3, and (h) capacitor 4?

Module 25-6  Dielectrics and Gauss’ Law

**47 SSM ILW** A certain substance has a dielectric constant of 2.8 and a dielectric strength of 18 MV/m. If it is used as the dielectric material in a parallel-plate capacitor, what minimum area should the plates of the capacitor have to obtain a capacitance of $7.0 \times 10^{-2}$ μF and to ensure that the capacitor will be able to withstand a potential difference of 4.0 kV?

**48** Figure 25-47 shows a parallel-plate capacitor with a plate area $A = 5.56$ cm$^2$ and separation $d = 5.56$ mm. The left half of the gap is filled with material of dielectric constant $\kappa_1 = 7.00$; the right half is filled with material of dielectric constant $\kappa_2 = 12.0$. What is the capacitance?

**49** Figure 25-48 shows a parallel-plate capacitor with a plate area $A = 7.89$ cm$^2$ and plate separation $d = 4.62$ mm. The top half of the gap is filled with material of dielectric constant $\kappa_1 = 11.0$; the bottom half is filled with material of dielectric constant $\kappa_2 = 12.0$. What is the capacitance?

**50** Figure 25-49 shows a parallel-plate capacitor of plate area $A = 10.5$ cm$^2$ and plate separation $2d = 7.12$ mm. The left half of the gap is filled with material of dielectric constant $\kappa_1 = 21.0$; the top of the right half is filled with material of dielectric constant $\kappa_2 = 42.0$; the bottom of the right half is filled with material of dielectric constant $\kappa_3 = 58.0$. What is the capacitance?

**51 SSM WWW** A parallel-plate capacitor has a capacitance of 100 pF, a plate area of 100 cm$^2$, and a mica dielectric ($\kappa = 5.4$) completely filling the space between the plates. At 50 V potential difference, calculate (a) the electric field magnitude $E$ in the mica, (b) the magnitude of the free charge on the plates, and (c) the magnitude of the induced surface charge on the mica.

**52** For the arrangement of Fig. 25-17, suppose that the battery remains connected while the dielectric slab is being introduced. Calculate (a) the capacitance, (b) the charge on the capacitor plates, (c) the electric field in the gap, and (d) the electric field in the slab, after the slab is in place.

**53** A parallel-plate capacitor has plates of area 0.12 m$^2$ and a separation of 1.2 cm. A battery charges the plates to a potential difference of 120 V and is then disconnected. A dielectric slab of thickness 4.0 mm and dielectric constant 4.8 is then placed symmetrically between the plates. (a) What is the capacitance before the slab is inserted? (b) What is the capacitance with the slab in place? What is the free charge $q$ (c) before and (d) after the slab is inserted? What is the magnitude of the electric field (e) in the space between the plates and dielectric and (f) in the dielectric itself? (g) With the slab in place, what is the potential difference across the plates? (h) How much external work is involved in inserting the slab?

**54** Two parallel plates of area 100 cm$^2$ are given charges of equal magnitudes $8.9 \times 10^{-7}$ C but opposite signs. The electric field within the dielectric material filling the space between the plates is $1.4 \times 10^6$ V/m. (a) Calculate the dielectric constant of the material. (b) Determine the magnitude of the charge induced on each dielectric surface.

**55** The space between two concentric conducting spherical shells of radii $b = 1.70$ cm and $a = 1.20$ cm is filled with a substance of dielectric constant $\kappa = 23.5$. A potential difference $V = 73.0$ V is applied across the inner and outer shells. Determine (a) the capacitance of the device, (b) the free charge $q$ on the inner shell, and (c) the charge $q'$ induced along the surface of the inner shell.

**Additional Problems**

**56** In Fig. 25-50, the battery potential difference $V$ is 10.0 V and each of the seven capacitors has capacitance $10.0 \mu F$. What is the charge on (a) capacitor 1 and (b) capacitor 2?

**57 SSM** In Fig. 25-51, $V = 9.0$ V, $C_1 = C_2 = 30 \mu F$, and $C_3 = C_4 = 15 \mu F$. What is the charge on capacitor 4?

**58** (a) If $C = 50 \mu F$ in Fig. 25-52, what is the equivalent capacitance between points A and B? (Hint: First imagine that a battery is connected between those two points.) (b) Repeat for points A and D.

**59** In Fig. 25-53, $V = 12$ V, $C_1 = C_4 = 2.0 \mu F$, $C_2 = 4.0 \mu F$, and $C_3 = 1.0 \mu F$. What is the charge on capacitor 4?

**60** *The chocolate crumb mystery.*

This story begins with Problem 60 in Chapter 23. As part of the investigation of the biscuit factory explosion, the electric potentials of the workers were measured as they emptied sacks of chocolate crumb powder into the loading bin, stirring up a cloud of the powder around themselves. Each worker had an electric potential of about 7.0 kV relative to the ground, which was taken as zero potential. (a) Assuming that each worker was effectively a capacitor with a typical capacitance of 200 pF, find the energy stored in that effective capacitor. If a single spark between the worker and any conducting object connected to the ground neutralized the worker, that energy would be transferred to the spark. According to measurements, a spark that could ignite a cloud of chocolate crumb powder, and thus set off an explosion, had to have an energy of at least 150 mJ. (b) Could a spark from a worker have set off an explosion in the cloud of powder in the loading bin? (The story continues with Problem 60 in Chapter 26.)

**61** Figure 25-54 shows capacitor 1 ($C_1 = 8.00 \mu F$), capacitor 2 ($C_2 = 6.00 \mu F$), and capacitor 3 ($C_3 =$
70 A slab of copper of thickness \( b = 2.00 \text{ mm} \) is thrust into a parallel-plate capacitor of plate area \( A = 2.40 \text{ cm}^2 \) and plate separation \( d = 5.00 \text{ mm} \), as shown in Fig. 25-57; the slab is exactly halfway between the plates. (a) What is the capacitance after the slab is introduced? (b) If a charge \( q = 3.40 \mu \text{C} \) is maintained on the plates, what is the ratio of the stored energy before to that after the slab is inserted? (c) How much work is done on the slab as it is inserted? (d) Is the slab sucked in or must it be pushed in?

71 Repeat Problem 70, assuming that a potential difference \( V = 85.0 \text{ V} \), rather than the charge, is held constant.

72 A potential difference of 300 V is applied to a series connection of two capacitors of capacitances \( C_1 = 2.00 \mu \text{F} \) and \( C_2 = 8.00 \mu \text{F} \). What are (a) charge \( q_1 \) and (b) potential difference \( V_1 \) on capacitor 1 and (c) \( q_2 \) and (d) \( V_2 \) on capacitor 2? The charged capacitors are then disconnected from each other and from the battery. Then the capacitors are reconnected with plates of the same signs wired together (the battery is not used). What now are (e) \( q_1 \), (f) \( V_1 \), (g) \( q_2 \), and (h) \( V_2 \)? Suppose, instead, the capacitors charged in part (a) are reconnected with plates of opposite signs wired together. What now are (i) \( q_1 \), (j) \( V_1 \), (k) \( q_2 \), and (l) \( V_2 \)?

73 Figure 25-58 shows a four-capacitor arrangement that is connected to a larger circuit at points \( A \) and \( B \). The capacitances are \( C_1 = 10 \mu \text{F} \) and \( C_2 = C_3 = C_4 = 20 \mu \text{F} \). The charge on capacitor 1 is 30 \( \mu \text{C} \). What is the magnitude of the potential difference \( V_A - V_B \)?

74 You have two plates of copper, a sheet of mica (thickness = 0.10 mm, \( \kappa = 5.4 \)), a sheet of glass (thickness = 2.0 mm, \( \kappa = 7.0 \)), and a slab of paraffin (thickness = 1.0 cm, \( \kappa = 2.0 \)). To make a parallel-plate capacitor with the largest \( C \), which sheet should you place between the copper plates?

75 A capacitor of unknown capacitance \( C \) is charged to 100 V and connected across an initially uncharged 60 \( \mu \text{F} \) capacitor. If the final potential difference across the 60 \( \mu \text{F} \) capacitor is 40 V, what is \( C \)?

76 A 10 V battery is connected to a series of \( n \) capacitors, each of capacitance 2.0 \( \mu \text{F} \). If the total stored energy is 25 \( \mu \text{J} \), what is \( n \)?

77 SSM In Fig. 25-59, two parallel-plate capacitors \( A \) and \( B \) are connected in parallel across a 600 V battery. Each plate has area 80.0 cm\(^2\); the plate separations are 3.00 mm. Capacitor \( A \) is filled with air; capacitor \( B \) is filled with a dielectric of dielectric constant \( \kappa = 2.60 \). Find the magnitude of the electric field within \( A \) the dielectric of capacitor \( B \) and \( B \) the air of capacitor \( A \). What are the free charge densities \( \sigma \) on the higher-potential plate of (c) capacitor \( A \) and (d) capacitor \( B \)? (e) What is the induced charge density \( \sigma' \) on the top surface of the dielectric?

78 You have many 2.0 \( \mu \text{F} \) capacitors, each capable of withstanding 200 V without undergoing electrical breakdown (in which they conduct charge instead of storing it). How would you assemble a combination having an equivalent capacitance of (a) 0.40 \( \mu \text{F} \) and (b) 1.2 \( \mu \text{F} \), each combination capable of withstanding 1000 V?

79 A parallel-plate capacitor has charge \( q \) and plate area \( A \). (a) By finding the work needed to increase the plate separation from \( x \) to \( x + dx \), determine the force between the plates. (Hint: See Eq. 8-22.) (b) Then show that the force per unit area (the electric stress) acting on either plate is equal to the energy density \( \varepsilon_0 E^2/2 \) between the plates.

80 A capacitor is charged until its stored energy is 4.00 J. A second capacitor is then connected to it in parallel. (a) If the charge distributes equally, what is the total energy stored in the electric fields? (b) Where did the missing energy go?
CHAPTER 26
Current and Resistance

26-1 ELECTRIC CURRENT

Learning Objectives

After reading this module, you should be able to . . .

26.01 Apply the definition of current as the rate at which charge moves through a point, including solving for the amount of charge that passes the point in a given time interval.

26.02 Identify that current is normally due to the motion of conduction electrons that are driven by electric fields (such as those set up in a wire by a battery).

26.03 Identify a junction in a circuit and apply the fact that (due to conservation of charge) the total current into a junction must equal the total current out of the junction.

26.04 Explain how current arrows are drawn in a schematic diagram of a circuit, and identify that the arrows are not vectors.

Key Ideas

- An electric current $i$ in a conductor is defined by
  $$i = \frac{dq}{dt},$$
  where $dq$ is the amount of positive charge that passes in time $dt$.

- By convention, the direction of electric current is taken as the direction in which positive charge carriers would move even though (normally) only conduction electrons can move.

What Is Physics?

In the last five chapters we discussed electrostatics—the physics of stationary charges. In this and the next chapter, we discuss the physics of electric currents—that is, charges in motion.

Examples of electric currents abound and involve many professions. Meteorologists are concerned with lightning and with the less dramatic slow flow of charge through the atmosphere. Biologists, physiologists, and engineers working in medical technology are concerned with the nerve currents that control muscles and especially with how those currents can be reestablished after spinal cord injuries. Electrical engineers are concerned with countless electrical systems, such as power systems, lightning protection systems, information storage systems, and music systems. Space engineers monitor and study the flow of charged particles from our Sun because that flow can wipe out telecommunication systems in orbit and even power transmission systems on the ground. In addition to such scholarly work, almost every aspect of daily life now depends on information carried by electric currents, from stock trades to ATM transfers and from video entertainment to social networking.

In this chapter we discuss the basic physics of electric currents and why they can be established in some materials but not in others. We begin with the meaning of electric current.
Electric Current

Although an electric current is a stream of moving charges, not all moving charges constitute an electric current. If there is to be an electric current through a given surface, there must be a net flow of charge through that surface. Two examples clarify our meaning.

1. The free electrons (conduction electrons) in an isolated length of copper wire are in random motion at speeds of the order of $10^6$ m/s. If you pass a hypothetical plane through such a wire, conduction electrons pass through it in both directions at the rate of many billions per second—but there is no net transport of charge and thus no current through the wire. However, if you connect the ends of the wire to a battery, you slightly bias the flow in one direction, with the result that there now is a net transport of charge and thus an electric current through the wire.

2. The flow of water through a garden hose represents the directed flow of positive charge (the protons in the water molecules) at a rate of perhaps several million coulombs per second. There is no net transport of charge, however, because there is a parallel flow of negative charge (the electrons in the water molecules) of exactly the same amount moving in exactly the same direction.

In this chapter we restrict ourselves largely to the study—within the framework of classical physics—of steady currents of conduction electrons moving through metallic conductors such as copper wires.

As Fig. 26-1a reminds us, any isolated conducting loop—regardless of whether it has an excess charge—is at the same potential. No electric field can exist within it or along its surface. Although conduction electrons are available, no net electric force acts on them and thus there is no current.

If, as in Fig. 26-1b, we insert a battery in the loop, the conducting loop is no longer at a single potential. Electric fields act inside the material making up the loop, exerting forces on the conduction electrons, causing them to move and thus establishing a current. After a very short time, the electron flow reaches a constant value and the current is in its steady state (it does not vary with time).

Figure 26-2 shows a section of a conductor, part of a conducting loop in which current has been established. If charge $dq$ passes through a hypothetical plane (such as $aa'$) in time $dt$, then the current $i$ through that plane is defined as

$$i = \frac{dq}{dt}, \quad \text{(definition of current).} \quad (26-1)$$

We can find the charge that passes through the plane in a time interval extending from 0 to $t$ by integration:

$$q = \int_0^t i \, dt, \quad (26-2)$$

in which the current $i$ may vary with time.

Under steady-state conditions, the current is the same for planes $aa'$, $bb'$, and $cc'$ and indeed for all planes that pass completely through the conductor, no matter what their location or orientation. This follows from the fact that charge is conserved. Under the steady-state conditions assumed here, an electron must pass through plane $aa'$ for every electron that passes through plane $cc'$. In the same way, if we have a steady flow of water through a garden hose, a drop of water must leave the nozzle for every drop that enters the hose at the other end. The amount of water in the hose is a conserved quantity.

The SI unit for current is the coulomb per second, or the ampere (A), which is an SI base unit:

$$1 \text{ ampere} = 1 \text{ A} = 1 \text{ coulomb per second} = 1 \text{ C/s}.$$

The formal definition of the ampere is discussed in Chapter 29.
Current, as defined by Eq. 26-1, is a scalar because both charge and time in that equation are scalars. Yet, as in Fig. 26-1b, we often represent a current with an arrow to indicate that charge is moving. Such arrows are not vectors, however, and they do not require vector addition. Figure 26-3a shows a conductor with current $i_0$ splitting at a junction into two branches. Because charge is conserved, the magnitudes of the currents in the branches must add to yield the magnitude of the current in the original conductor, so that

$$i_0 = i_1 + i_2.$$  \hspace{1cm} (26-3)

As Fig. 26-3b suggests, bending or reorienting the wires in space does not change the validity of Eq. 26-3. Current arrows show only a direction (or sense) of flow along a conductor, not a direction in space.

**The Directions of Currents**

In Fig. 26-1b we drew the current arrows in the direction in which positively charged particles would be forced to move through the loop by the electric field. Such positive charge carriers, as they are often called, would move away from the positive battery terminal and toward the negative terminal. Actually, the charge carriers in the copper loop of Fig. 26-1b are electrons and thus are negatively charged. The electric field forces them to move in the direction opposite the current arrows, from the negative terminal to the positive terminal. For historical reasons, however, we use the following convention:

A current arrow is drawn in the direction in which positive charge carriers would move, even if the actual charge carriers are negative and move in the opposite direction.

We can use this convention because in most situations, the assumed motion of positive charge carriers in one direction has the same effect as the actual motion of negative charge carriers in the opposite direction. (When the effect is not the same, we shall drop the convention and describe the actual motion.)

**Checkpoint 1**

The figure here shows a portion of a circuit. What are the magnitude and direction of the current $i$ in the lower right-hand wire?

**Sample Problem 26.01**  **Current is the rate at which charge passes a point**

Water flows through a garden hose at a volume flow rate $dV/dt$ of 450 cm$^3$/s. What is the current of negative charge?

**Calculations:** We can write the current in terms of the number of molecules that pass through such a plane per second as

$$i = \left(\frac{\text{charge}}{\text{electron}}\right) \left(\frac{\text{electrons}}{\text{molecule}}\right) \left(\frac{\text{molecules}}{\text{per second}}\right)$$

or

$$i = (e)(10) \frac{dN}{dt}.$$
We substitute 10 electrons per molecule because a water (H₂O) molecule contains 8 electrons in the single oxygen atom and 1 electron in each of the two hydrogen atoms.

We can express the rate \( \frac{dN}{dt} \) in terms of the given volume flow rate \( \frac{dV}{dt} \) by first writing

\[
\left( \text{molecules per second} \right) = \left( \text{molecules per mole} \right) \times \left( \text{moles per unit mass} \right) \times \left( \text{mass per unit volume} \right).
\]

“Molecules per mole” is Avogadro’s number \( N_A \). “Moles per unit mass” is the inverse of the mass per mole, which is the (mass) density \( \rho_{\text{mass}} \) of water. The volume per second is the volume flow rate \( \frac{dV}{dt} \). Thus, we have

\[
\frac{dN}{dt} = N_A \left( \frac{1}{M} \right) \rho_{\text{mass}} \left( \frac{dV}{dt} \right) = \frac{N_A \rho_{\text{mass}}}{M} \frac{dV}{dt}.
\]

Substituting this into the equation for \( i \), we find

\[
i = 10eN_A M^{-1} \rho_{\text{mass}} \frac{dV}{dt}.
\]

We know that Avogadro’s number \( N_A \) is \( 6.02 \times 10^{23} \) molecules/mol, or \( 6.02 \times 10^{23} \text{ mol}^{-1} \), and from Table 15-1 we know that the density of water \( \rho_{\text{mass}} \) under normal conditions is \( 1000 \text{ kg/m}^3 \). We can get the molar mass of water from the molar masses listed in Appendix F (in grams per mole): We add the molar mass of oxygen (16 g/mol) to twice the molar mass of hydrogen (1 g/mol), obtaining 18 g/mol = 0.018 kg/mol. So, the current of negative charge due to the electrons in the water is

\[
i = (10)(1.6 \times 10^{-19} \text{ C})(6.02 \times 10^{23} \text{ mol}^{-1}) \\
\times (0.018 \text{ kg/mol})^{-1}(1000 \text{ kg/m}^3)(450 \times 10^{-6} \text{ m}^3/\text{s})
\]

\[
= 2.41 \times 10^7 \text{ C/s} = 2.41 \times 10^7 \text{ A}
\]

\[
= 24.1 \text{ MA.} \quad \text{(Answer)}
\]

This current of negative charge is exactly compensated by a current of positive charge associated with the nuclei of the three atoms that make up the water molecule. Thus, there is no net flow of charge through the hose.

## 26-2 CURRENT DENSITY

### Learning Objectives

**After reading this module, you should be able to . . .**

- **26.05** Identify a current density and a current density vector.
- **26.06** For current through an area element on a cross section through a conductor (such as a wire), identify the element’s area vector \( d\vec{A} \).
- **26.07** Find the current through a cross section of a conductor by integrating the dot product of the current density vector \( \vec{J} \) and the element area vector \( d\vec{A} \) over the full cross section.
- **26.08** For the case where current is uniformly spread over a cross section in a conductor, apply the relationship between the current \( i \), the current density magnitude \( J \), and the area \( A \).
- **26.09** Identify streamlines.
- **26.10** Explain the motion of conduction electrons in terms of their drift speed.
- **26.11** Distinguish the drift speeds of conduction electrons from their random-motion speeds, including relative magnitudes.
- **26.12** Identify carrier charge density \( n \).
- **26.13** Apply the relationship between current density \( J \), charge carrier density \( n \), and charge carrier drift speed \( v_d \).

### Key Ideas

- Current \( i \) (a scalar quantity) is related to current density \( \vec{J} \) (a vector quantity) by

\[
i = \int \vec{J} \cdot d\vec{A},
\]

where \( d\vec{A} \) is a vector perpendicular to a surface element of area \( dA \) and the integral is taken over any surface cutting across the conductor. The current density \( \vec{J} \) has the same direction as the velocity of the moving charges if they are positive and the opposite direction if they are negative.

- When an electric field \( \vec{E} \) is established in a conductor, the charge carriers (assumed positive) acquire a drift speed \( v_d \) in the direction of \( \vec{E} \).

- The drift velocity \( v_d \) is related to the current density by

\[
\vec{J} = (ne)v_d,
\]

where \( ne \) is the carrier charge density.
**Current Density**

Sometimes we are interested in the current $i$ in a particular conductor. At other times we take a localized view and study the flow of charge through a cross section of the conductor at a particular point. To describe this flow, we can use the **current density** $\mathbf{J}$, which has the same direction as the velocity of the moving charges if they are positive and the opposite direction if they are negative. For each element of the cross section, the magnitude $J$ is equal to the current per unit area through that element. We can write the amount of current through the element as $\mathbf{J} \cdot d\mathbf{A}$, where $d\mathbf{A}$ is the area vector of the element, perpendicular to the element. The total current through the surface is then

$$i = \int \mathbf{J} \cdot d\mathbf{A}. \tag{26-4}$$

If the current is uniform across the surface and parallel to $d\mathbf{A}$, then $\mathbf{J}$ is also uniform and parallel to $d\mathbf{A}$. Then Eq. 26-4 becomes

$$i = \int J dA = J \int dA = JA,$$

so

$$J = \frac{i}{A}. \tag{26-5}$$

where $A$ is the total area of the surface. From Eq. 26-4 or 26-5 we see that the SI unit for current density is the ampere per square meter ($\text{A/m}^2$).

In Chapter 22 we saw that we can represent an electric field with electric field lines. Figure 26-4 shows how current density can be represented with a similar set of lines, which we can call *streamlines*. The current, which is toward the right in Fig. 26-4, makes a transition from the wider conductor at the left to the narrower conductor at the right. Because charge is conserved during the transition, the amount of charge and thus the amount of current cannot change. However, the current density does change—it is greater in the narrower conductor. The spacing of the streamlines suggests this increase in current density; streamlines that are closer together imply greater current density.

**Drift Speed**

When a conductor does not have a current through it, its conduction electrons move randomly, with no net motion in any direction. When the conductor does have a current through it, these electrons actually still move randomly, but now they tend to *drift* with a **drift speed** $v_d$ in the direction opposite that of the applied electric field that causes the current. The drift speed is tiny compared with the speeds in the random motion. For example, in the copper conductors of household wiring, electron drift speeds are perhaps $10^{-5}$ or $10^{-4}$ m/s, whereas the random-motion speeds are around $10^6$ m/s.

We can use Fig. 26-5 to relate the drift speed $v_d$ of the conduction electrons in a current through a wire to the magnitude $J$ of the current density in the wire. For
convenience, Fig. 26-5 shows the equivalent drift of positive charge carriers in the direction of the applied electric field \( \vec{E} \). Let us assume that these charge carriers all move with the same drift speed \( v_d \) and that the current density \( J \) is uniform across the wire’s cross-sectional area \( A \). The number of charge carriers in a length \( L \) of the wire is \( nAL \), where \( n \) is the number of carriers per unit volume. The total charge of the carriers in the length \( L \), each with charge \( e \), is then

\[
q = (nAL)e.
\]

Because the carriers all move along the wire with speed \( v_d \), this total charge moves through any cross section of the wire in the time interval

\[
t = \frac{L}{v_d}.
\]

Equation 26-1 tells us that the current \( i \) is the time rate of transfer of charge across a cross section, so here we have

\[
i = \frac{q}{t} = \frac{nALe}{L/v_d} = nAev_d.
\]  

(26-6)

Solving for \( v_d \) and recalling Eq. 26-5 \((J = i/A)\), we obtain

\[
v_d = \frac{i}{nAe} = \frac{J}{ne}
\]

or, extended to vector form,

\[
\vec{J} = (ne)\vec{v}_d.
\]  

(26-7)

Here the product \( ne \), whose SI unit is the coulomb per cubic meter \((C/m^3)\), is the carrier charge density. For positive carriers, \( ne \) is positive and Eq. 26-7 predicts that \( \vec{J} \) and \( \vec{v}_d \) have the same direction. For negative carriers, \( ne \) is negative and \( \vec{J} \) and \( \vec{v}_d \) have opposite directions.

**Checkpoint 2**

The figure shows conduction electrons moving leftward in a wire. Are the following leftward or rightward: (a) the current \( i \), (b) the current density \( J \), (c) the electric field \( E \) in the wire?

---

**Sample Problem 26.02  Current density, uniform and nonuniform**

(a) The current density in a cylindrical wire of radius \( R = 2.0 \text{ mm} \) is uniform across a cross section of the wire and is \( J = 2.0 \times 10^5 \text{ A/m}^2 \). What is the current through the outer portion of the wire between radial distances \( R/2 \) and \( R \) (Fig. 26-6a)?

**KEY IDEA**

Because the current density is uniform across the cross section, the current density \( J \), the current \( i \), and the cross-sectional area \( A \) are related by Eq. 26-5 \((J = i/A)\).

**Calculations:** We want only the current through a reduced cross-sectional area \( A' \) of the wire (rather than the entire area), where

\[
A' = \pi R^2 - \pi \left(\frac{R}{2}\right)^2 = \pi \left(\frac{3R^2}{4}\right)
\]

\[
= \frac{3\pi}{4} (0.0020 \text{ m})^2 = 9.424 \times 10^{-6} \text{ m}^2.
\]

So, we rewrite Eq. 26-5 as

\[
i = JA'
\]

and then substitute the data to find

\[
i = (2.0 \times 10^5 \text{ A/m}^2)(9.424 \times 10^{-6} \text{ m}^2)
\]

\[
= 1.9 \text{ A}.
\]  

(Answer)
(b) Suppose, instead, that the current density through a cross section varies with radial distance $r$ as $J = ar^2$, in which $a = 3.0 \times 10^{11}$ A/m$^4$ and $r$ is in meters. What now is the current through the same outer portion of the wire?

**KEY IDEA**

Because the current density is not uniform across a cross section of the wire, we must resort to Eq. 26-4 ($i = \int \vec{J} \cdot d\vec{A}$) and integrate the current density over the portion of the wire from $r = R/2$ to $r = R$.

**Calculations:** The current density vector $\vec{J}$ (along the wire’s length) and the differential area vector $d\vec{A}$ (perpendicular to a cross section of the wire) have the same direction. Thus,

$$\vec{J} \cdot d\vec{A} = J dA \cos \theta = J dA.$$

We need to replace the differential area $dA$ with something we can actually integrate between the limits $r = R/2$ and $r = R$. The simplest replacement (because $J$ is given as a function of $r$) is the area $2\pi r \, dr$ of a thin ring of circumference $2\pi r$ and width $dr$ (Fig. 26-6b). We can then integrate with $r$ as the variable of integration. Equation 26-4 then gives us

$$i = \int_{R/2}^{R} J \, dr = \int_{R/2}^{R} \int_{0}^{2\pi} J(r) \, r \, dr \, d\theta.$$

We will use cylindrical coordinates, where $\theta$ is in radians, and $r$ is the radial distance. The current density is $J(r) = ar^2$, so

$$dA = r \, dr \, d\theta.$$

The current within the ring is the product of the current density and the ring’s area.

**Figure 26-6** (a) Cross section of a wire of radius $R$. If the current density is uniform, the current is just the product of the current density and the area. (b)–(e) If the current is nonuniform, we must first find the current through a thin ring and then sum (via integration) the currents in all such rings in the given area.
Sample Problem 26.03 In a current, the conduction electrons move very slowly

What is the drift speed of the conduction electrons in a copper wire with radius \( r = 900 \, \mu\text{m} \) when it has a uniform current \( i = 17 \, \text{mA} \)? Assume that each copper atom contributes one conduction electron to the current and that the current density is uniform across the wire’s cross section.

**KEY IDEAS**

1. The drift speed \( v_d \) is related to the current density \( J \) and the number \( n \) of conduction electrons per unit volume according to Eq. 26-7, which we can write as \( J = nev_d \).

2. Because the current density is uniform, its magnitude \( J \) is related to the given current \( i \) and wire size by Eq. 26-5 \( (J = i/A, \text{where } A \text{ is the cross-sectional area of the wire}) \).

3. Because we assume one conduction electron per atom, the number \( n \) of conduction electrons per unit volume is the same as the number of atoms per unit volume.

**Calculations:** Let us start with the third idea by writing

\[
 n = \frac{\text{atoms per unit volume}}{\text{atoms per mole}} \times \frac{\text{moles per unit}}{\text{mass per unit}} \times \frac{\text{mass}}{\text{volume}}.
\]

The number of atoms per mole is just Avogadro’s number \( N_A \) (= 6.02 \times 10^{23} \, \text{mol}^{-1} \). Moles per unit mass is the inverse of the mass per mole, which here is the molar mass \( M \) of copper. The mass per unit volume is the (mass) density \( \rho_{\text{mass}} \) of copper. Thus,

\[
 n = N_A \left( \frac{1}{M} \right) \rho_{\text{mass}} = \frac{N_A \rho_{\text{mass}}}{M}.
\]

Taking copper’s molar mass \( M \) and density \( \rho_{\text{mass}} \) from Appendix F, we then have (with some conversions of units)

\[
 n = \frac{(6.02 \times 10^{23} \, \text{mol}^{-1})(8.96 \times 10^3 \, \text{kg/m}^3)}{6.354 \times 10^3 \, \text{kg/mol}} = 8.49 \times 10^{28} \, \text{electrons/m}^3
\]

or \( n = 8.49 \times 10^{28} \, \text{m}^{-3} \).

Next let us combine the first two key ideas by writing

\[
 \frac{i}{A} = nev_d.
\]

Substituting for \( A \) with \( \pi r^2 \) (= 2.54 \times 10^{-6} \, \text{m}^2 \) and solving for \( v_d \), we then find

\[
 v_d = \frac{i}{ne(\pi r^2)} = \frac{17 \times 10^{-3} \, \text{A}}{(8.49 \times 10^{28} \, \text{m}^{-3})(1.6 \times 10^{-19} \, \text{C})(2.54 \times 10^{-6} \, \text{m}^2)} = 4.9 \times 10^{-7} \, \text{m/s},
\]

(Answer)

which is only 1.8 mm/h, slower than a sluggish snail.

**Lights are fast:** You may well ask: “If the electrons drift so slowly, why do the room lights turn on so quickly when I throw the switch?” Confusion on this point results from not distinguishing between the drift speed of the electrons and the speed at which changes in the electric field configuration travel along wires. This latter speed is nearly that of light; electrons everywhere in the wire begin drifting almost at once, including into the lightbulbs. Similarly, when you open the valve on your garden hose with the hose full of water, a pressure wave travels along the hose at the speed of sound in water. The speed at which the water itself moves through the hose—measured perhaps with a dye marker—is much slower.
Resistance and Resistivity

If we apply the same potential difference between the ends of geometrically similar rods of copper and of glass, very different currents result. The characteristic of the conductor that enters here is its electrical resistance. We determine the resistance between any two points of a conductor by applying a potential difference \( V \) between those points and measuring the current \( i \) that results. The resistance \( R \) is then

\[
R = \frac{V}{i},
\]

(definition of \( R \)).

The SI unit for resistance that follows from Eq. 26-8 is the volt per ampere. This combination occurs so often that we give it a special name, the ohm (symbol \( \Omega \)); that is,

\[
1 \text{ ohm} = 1 \Omega = 1 \text{ volt per ampere} = 1 \text{ V/A}.
\]

(26-9)

A conductor whose function in a circuit is to provide a specified resistance is called a resistor (see Fig. 26-7). In a circuit diagram, we represent a resistor and a resistance with the symbol \( \bigcirc \). If we write Eq. 26-8 as

\[
i = \frac{V}{R},
\]

we see that, for a given \( V \), the greater the resistance, the smaller the current.

The resistance of a conductor depends on the manner in which the potential difference is applied to it. Figure 26-8, for example, shows a given potential difference applied in two different ways to the same conductor. As the current density streamlines suggest, the currents in the two cases—hence the measured resistances—will be different. Unless otherwise stated, we shall assume that any given potential difference is applied as in Fig. 26-8b.

*An alloy specifically designed to have a small value of \( \alpha \).

*Pure silicon doped with phosphorus impurities to a charge carrier density of \( 10^{25} \) m⁻³.

*Pure silicon doped with aluminum impurities to a charge carrier density of \( 10^{21} \) m⁻³.

As we have done several times in other connections, we often wish to take a general view and deal not with particular objects but with materials. Here we do so by focusing not on the potential difference \( V \) across a particular resistor but on the electric field \( \vec{E} \) at a point in a resistive material. Instead of dealing with the current \( i \) through the resistor, we deal with the current density \( \vec{J} \) at the point in question. Instead of the resistance \( R \) of an object, we deal with the resistivity \( \rho \) of the material:

\[
\rho = \frac{E}{J} \quad \text{(definition of } \rho \text{).} \tag{26-10}
\]

(Compare this equation with Eq. 26-8.)

If we combine the SI units of \( E \) and \( J \) according to Eq. 26-10, we get, for the unit of \( \rho \), the ohm-meter (Ω·m):

\[
\frac{\text{unit } (E)}{\text{unit } (J)} = \frac{V}{A/m^2} = \frac{V}{A} \text{ m} = \Omega \cdot \text{m}.
\]

(Do not confuse the ohm-meter, the unit of resistivity, with the ohmmeter, which is an instrument that measures resistance.) Table 26-1 lists the resistivities of some materials.

We can write Eq. 26-10 in vector form as

\[
\vec{E} = \rho \vec{J}. \tag{26-11}
\]

Equations 26-10 and 26-11 hold only for isotropic materials—materials whose electrical properties are the same in all directions.

We often speak of the conductivity \( \sigma \) of a material. This is simply the reciprocal of its resistivity, so

\[
\sigma = \frac{1}{\rho} \quad \text{(definition of } \sigma \text{).} \tag{26-12}
\]

The SI unit of conductivity is the reciprocal ohm-meter, (Ω·m)⁻¹. The unit name mhos per meter is sometimes used (mho is ohm backwards). The definition of \( \sigma \) allows us to write Eq. 26-11 in the alternative form

\[
\vec{J} = \sigma \vec{E}. \tag{26-13}
\]

Calculating Resistance from Resistivity

We have just made an important distinction:

Resistance is a property of an object. Resistivity is a property of a material.

If we know the resistivity of a substance such as copper, we can calculate the resistance of a length of wire made of that substance. Let \( A \) be the cross-sectional area of the wire, let \( L \) be its length, and let a potential difference \( V \) exist between its ends (Fig. 26-9). If the streamlines representing the current density are uniform throughout the wire, the electric field and the current density will be constant for all points within the wire and, from Eqs. 24-42 and 26-5, will have the values

\[
E = \frac{V}{L} \quad \text{and} \quad J = \frac{i}{A}. \tag{26-14}
\]

We can then combine Eqs. 26-10 and 26-14 to write

\[
\rho = \frac{E}{J} = \frac{V/L}{i/A}. \tag{26-15}
\]
However, $V/i$ is the resistance $R$, which allows us to recast Eq. 26-15 as

$$R = \rho \frac{L}{A}. \quad (26-16)$$

Equation 26-16 can be applied only to a homogeneous isotropic conductor of uniform cross section, with the potential difference applied as in Fig. 26-8b. The macroscopic quantities $V$, $i$, and $R$ are of greatest interest when we are making electrical measurements on specific conductors. They are the quantities that we read directly on meters. We turn to the microscopic quantities $E$, $J$, and $\rho$ when we are interested in the fundamental electrical properties of materials.

**Checkpoint 3**

The figure here shows three cylindrical copper conductors along with their face areas and lengths. Rank them according to the current through them, greatest first, when the same potential difference $V$ is placed across their lengths.

![Diagram of conductors]

Variation with Temperature

The values of most physical properties vary with temperature, and resistivity is no exception. Figure 26-10, for example, shows the variation of this property for copper over a wide temperature range. The relation between temperature and resistivity for copper—and for metals in general—is fairly linear over a rather broad temperature range. For such linear relations we can write an empirical approximation that is good enough for most engineering purposes:

$$\rho - \rho_0 = \rho_0 \alpha (T - T_0). \quad (26-17)$$

Here $T_0$ is a selected reference temperature and $\rho_0$ is the resistivity at that temperature. Usually $T_0 = 293 \text{ K}$ (room temperature), for which $\rho_0 = 1.69 \times 10^{-8} \text{ } \Omega \cdot \text{m}$ for copper.

Because temperature enters Eq. 26-17 only as a difference, it does not matter whether you use the Celsius or Kelvin scale in that equation because the sizes of degrees on these scales are identical. The quantity $\alpha$ in Eq. 26-17, called the *temperature coefficient of resistivity*, is chosen so that the equation gives good agreement with experiment for temperatures in the chosen range. Some values of $\alpha$ for metals are listed in Table 26-1.

![Graph of resistivity vs. temperature]

**Figure 26-10** The resistivity of copper as a function of temperature. The dot on the curve marks a convenient reference point at temperature $T_0 = 293 \text{ K}$ and resistivity $\rho_0 = 1.69 \times 10^{-8} \text{ } \Omega \cdot \text{m}$. Resistivity can depend on temperature.
Sample Problem 26.04  A material has resistivity, a block of the material has resistance

A rectangular block of iron has dimensions 1.2 cm × 1.2 cm × 15 cm. A potential difference is to be applied to the block between parallel sides and in such a way that those sides are equipotential surfaces (as in Fig. 26-8b). What is the resistance of the block if the two parallel sides are (1) the square ends (with dimensions 1.2 cm × 1.2 cm) and (2) two rectangular sides (with dimensions 1.2 cm × 15 cm)?

Calculations: For arrangement 1, we have \( L = 15 \text{ cm} = 0.15 \text{ m} \) and

\[
A = (1.2 \text{ cm})^2 = 1.44 \times 10^{-4} \text{ m}^2.
\]

Substituting into Eq. 26-16 with the resistivity \( \rho \) from Table 26-1, we then find that for arrangement 1,

\[
R = \frac{\rho L}{A} = \frac{(9.68 \times 10^{-8} \text{ } \Omega \cdot \text{ m})(0.15 \text{ m})}{1.44 \times 10^{-4} \text{ m}^2} = 1.0 \times 10^{-4} \Omega = 100 \mu \Omega. \quad \text{(Answer)}
\]

Similarly, for arrangement 2, with distance \( L = 1.2 \text{ cm} \) and area \( A = (1.2 \text{ cm})(15 \text{ cm}) \), we obtain

\[
R = \frac{\rho L}{A} = \frac{(9.68 \times 10^{-8} \text{ } \Omega \cdot \text{ m})(1.2 \times 10^{-2} \text{ m})}{1.80 \times 10^{-3} \text{ m}^2} = 6.5 \times 10^{-7} \Omega = 0.65 \mu \Omega. \quad \text{(Answer)}
\]
Figure 26-11a shows how to distinguish such devices. A potential difference $V$ is applied across the device being tested, and the resulting current $i$ through the device is measured as $V$ is varied in both magnitude and polarity. The polarity of $V$ is arbitrarily taken to be positive when the left terminal of the device is at a higher potential than the right terminal. The direction of the resulting current (from left to right) is arbitrarily assigned a plus sign. The reverse polarity of $V$ (with the right terminal at a higher potential) is then negative; the current it causes is assigned a minus sign.

Figure 26-11b is a plot of $i$ versus $V$ for one device. This plot is a straight line passing through the origin, so the ratio $i/V$ (which is the slope of the straight line) is the same for all values of $V$. This means that the resistance $R = V/i$ of the device is independent of the magnitude and polarity of the applied potential difference $V$.

Figure 26-11c is a plot for another conducting device. Current can exist in this device only when the polarity of $V$ is positive and the applied potential difference is more than about 1.5 V. When current does exist, the relation between $i$ and $V$ is not linear; it depends on the value of the applied potential difference $V$.

We distinguish between the two types of device by saying that one obeys Ohm’s law and the other does not.

**Ohm’s law** is an assertion that the current through a device is always directly proportional to the potential difference applied to the device.

(This assertion is correct only in certain situations; still, for historical reasons, the term “law” is used.) The device of Fig. 26-11b—which turns out to be a 1000 Ω resistor—obeys Ohm’s law. The device of Fig. 26-11c—which is called a *pn* junction diode—does not.

A conducting device obeys Ohm’s law when the resistance of the device is independent of the magnitude and polarity of the applied potential difference.

It is often contended that $V = iR$ is a statement of Ohm’s law. That is not true! This equation is the defining equation for resistance, and it applies to all conducting devices, whether they obey Ohm’s law or not. If we measure the potential difference $V$ across, and the current $i$ through, any device, even a *pn* junction diode, we can find its resistance at that value of $V$ as $R = V/i$. The essence of Ohm’s law, however, is that a plot of $i$ versus $V$ is linear; that is, $R$ is independent of $V$. We can generalize this for conducting materials by using Eq. 26-11 ($E = \rho J$):

A conducting material obeys Ohm’s law when the resistivity of the material is independent of the magnitude and direction of the applied electric field.

All homogeneous materials, whether they are conductors like copper or semiconductors like pure silicon or silicon containing special impurities, obey Ohm’s law within some range of values of the electric field. If the field is too strong, however, there are departures from Ohm’s law in all cases.

**Checkpoint 4**

The following table gives the current $i$ (in amperes) through two devices for several values of potential difference $V$ (in volts). From these data, determine which device does not obey Ohm’s law.

A Microscopic View of Ohm’s Law

To find out why particular materials obey Ohm’s law, we must look into the details of the conduction process at the atomic level. Here we consider only conduction in metals, such as copper. We base our analysis on the free-electron model, in which we assume that the conduction electrons in the metal are free to move throughout the volume of a sample, like the molecules of a gas in a closed container. We also assume that the electrons collide not with one another but only with atoms of the metal.

According to classical physics, the electrons should have a Maxwellian speed distribution somewhat like that of the molecules in a gas (Module 19-6), and thus the average electron speed should depend on the temperature. The motions of electrons are, however, governed not by the laws of classical physics but by those of quantum physics. As it turns out, an assumption that is much closer to the quantum reality is that conduction electrons in a metal move with a single effective speed $v_{\text{eff}}$, and this speed is essentially independent of the temperature. For copper, $v_{\text{eff}} \approx 1.6 \times 10^6$ m/s.

When we apply an electric field to a metal sample, the electrons modify their random motions slightly and drift very slowly—in a direction opposite that of the field—with an average drift speed $v_d$. The drift speed in a typical metallic conductor is about $5 \times 10^{-7}$ m/s, less than the effective speed ($1.6 \times 10^6$ m/s) by many orders of magnitude. Figure 26-12 suggests the relation between these two speeds. The gray lines show a possible random path for an electron in the absence of an applied field; the electron proceeds from $A$ to $B$, making six collisions along the way. The green lines show how the same events might occur when an electric field $E$ is applied. We see that the electron drifts steadily to the right, ending at $B'$ rather than at $B$. Figure 26-12 was drawn with the assumption that $v_d \approx 0.02v_{\text{eff}}$. However, because the actual value is more like $v_d \approx (10^{-13})v_{\text{eff}}$, the drift displayed in the figure is greatly exaggerated.

The motion of conduction electrons in an electric field $E$ is thus a combination of the motion due to random collisions and that due to the effect of the electric field on the electrons.

If an electron of mass $m$ is placed in an electric field of magnitude $E$, the electron will experience an acceleration given by Newton’s second law:

$$a = \frac{F}{m} = \frac{eE}{m}. \tag{26-18}$$

After a typical collision, each electron will—so to speak—completely lose its memory of its previous drift velocity, starting fresh and moving off in a random direction. In the average time $\tau$ between collisions, the average electron will acquire a drift speed of $v_d = a\tau$. Moreover, if we measure the drift speeds of all the electrons at any instant, we will find that their average drift speed is also $a\tau$. Thus, at any instant, on average, the electrons will have drift speed $v_d = a\tau$. Then Eq. 26-18 gives us

$$v_d = a\tau = \frac{eE\tau}{m}. \tag{26-19}$$

Figure 26-12 The gray lines show an electron moving from $A$ to $B$, making six collisions en route. The green lines show what the electron’s path might be in the presence of an applied electric field $E$. Note the steady drift in the direction of $-E$. (Actually, the green lines should be slightly curved, to represent the parabolic paths followed by the electrons between collisions, under the influence of an electric field.)
Combining this result with Eq. 26-7 ($\vec{J} = ne\vec{v}_d$), in magnitude form, yields

$$v_d = \frac{J}{ne} = \frac{eE\tau}{m},$$

(26-20)

which we can write as

$$E = \left(\frac{m}{e^n\tau}\right)J.$$  

(26-21)

Comparing this with Eq. 26-11 ($\vec{E} = \rho\vec{J}$), in magnitude form, leads to

$$\rho = \frac{m}{e^n\tau}.$$  

(26-22)

Equation 26-22 may be taken as a statement that metals obey Ohm's law if we can show that, for metals, their resistivity $\rho$ is a constant, independent of the strength of the applied electric field $E$. Let's consider the quantities in Eq. 26-22. We can reasonably assume that $n$, the number of conduction electrons per volume, is independent of the field, and $m$ and $e$ are constants. Thus, we only need to convince ourselves that $\tau$, the average time (or mean free time) between collisions, is a constant, independent of the strength of the applied electric field. Indeed, $\tau$ can be considered to be a constant because the drift speed $v_d$ caused by the field is so much smaller than the effective speed $v_{\text{eff}}$ that the electron speed—and thus $\tau$—is hardly affected by the field. Thus, because the right side of Eq. 26-22 is independent of the field magnitude, metals obey Ohm’s law.

**Sample Problem 26.05  Mean free time and mean free distance**

(a) What is the mean free time $\tau$ between collisions for the conduction electrons in copper?

**Calculations:** That equation gives us

$$\tau = \frac{m}{ne^2\rho}.$$  

(26-23)

The number of conduction electrons per unit volume in copper is $8.49 \times 10^{28} \text{ m}^{-3}$. We take the value of $\rho$ from Table 26-1. The denominator then becomes

$$(8.49 \times 10^{28} \text{ m}^{-3})(1.6 \times 10^{-19} \text{ C})^2(1.69 \times 10^{-8}\Omega\cdot\text{m}) = 3.67 \times 10^{-17}\text{ C}^2\cdot\Omega/\text{m}^2 = 3.67 \times 10^{-17}\text{ kg/s},$$

where we converted units as

$$\frac{\text{C}^2\cdot\Omega}{\text{m}^2} = \frac{\text{C}^2}{\text{m}^2}\cdot\frac{\text{V}}{\text{A}} = \frac{\text{C}^2\cdot\text{J}/\text{C}}{\text{m}^2\cdot\text{C}/\text{s}} = \frac{\text{kg}\cdot\text{m}^2/\text{s}^2}{\text{m}^2/\text{s}} = \frac{\text{kg}}{\text{s}},$$

Using these results and substituting for the electron mass $m$, we then have

$$\tau = \frac{9.1 \times 10^{-31}\text{ kg}}{3.67 \times 10^{-17}\text{ kg/s}} = 2.5 \times 10^{-14}\text{ s}. \quad \text{(Answer)}$$

(b) The mean free path $\lambda$ of the conduction electrons in a conductor is the average distance traveled by an electron between collisions. (This definition parallels that in Module 19-5 for the mean free path of molecules in a gas.) What is $\lambda$ for the conduction electrons in copper, assuming that their effective speed $v_{\text{eff}}$ is $1.6 \times 10^6\text{ m/s}$?

**Calculations:** For the electrons in copper, this gives us

$$\lambda = v_{\text{eff}}\tau.$$  

(26-24)

$$= (1.6 \times 10^6\text{ m/s})(2.5 \times 10^{-14}\text{ s})$$

$$= 4.0 \times 10^{-8}\text{ m} = 40\text{ nm}. \quad \text{(Answer)}$$

This is about 150 times the distance between nearest-neighbor atoms in a copper lattice. Thus, on the average, each conduction electron passes many copper atoms before finally hitting one.
CHAPTER 26
CURRENT AND RESISTANCE

26-5 POWER, SEMICONDUCTORS, SUPERCONDUCTORS

Learning Objectives
After reading this module, you should be able to . . .

26.27 Explain how conduction electrons in a circuit lose energy in a resistive device.
26.28 Identify that power is the rate at which energy is transferred from one type to another.
26.29 For a resistive device, apply the relationships between power \( P \), current \( i \), voltage \( V \), and resistance \( R \).
26.30 For a battery, apply the relationship between power \( P \), current \( i \), and potential difference \( V \).
26.31 Apply the conservation of energy to a circuit with a battery and a resistive device to relate the energy transfers in the circuit.
26.32 Distinguish conductors, semiconductors, and superconductors.

Key Ideas

- The power \( P \), or rate of energy transfer, in an electrical device across which a potential difference \( V \) is maintained is
  \[ P = iV. \]
- If the device is a resistor, the power can also be written as
  \[ P = i^2R = \frac{V^2}{R}. \]
- In a resistor, electric potential energy is converted to internal thermal energy via collisions between charge carriers and atoms.
- Semiconductors are materials that have few conduction electrons but can become conductors when they are doped with other atoms that contribute charge carriers.
- Superconductors are materials that lose all electrical resistance. Most such materials require very low temperatures, but some become superconducting at temperatures as high as room temperature.

Power in Electric Circuits

Figure 26-13 shows a circuit consisting of a battery B that is connected by wires, which we assume have negligible resistance, to an unspecified conducting device. The device might be a resistor, a storage battery (a rechargeable battery), a motor, or some other electrical device. The battery maintains a potential difference of magnitude \( V \) across its own terminals and thus (because of the wires) across the terminals of the unspecified device, with a greater potential at terminal \( a \) of the device than at terminal \( b \).

Because there is an external conducting path between the two terminals of the battery, and because the potential differences set up by the battery are maintained, a steady current \( i \) is produced in the circuit, directed from terminal \( a \) to terminal \( b \). The amount of charge \( dq \) that moves between those terminals in time interval \( dt \) is equal to \( i \, dt \). This charge \( dq \) moves through a decrease in potential of magnitude \( V \), and thus its electric potential energy decreases in magnitude by the amount

\[ dU = dq \, V = i \, dt \, V. \quad (26-25) \]

The principle of conservation of energy tells us that the decrease in electric potential energy from \( a \) to \( b \) is accompanied by a transfer of energy to some other form. The power \( P \) associated with that transfer is the rate of transfer \( dU/dt \), which is given by Eq. 26-25 as

\[ P = iV \quad \text{(rate of electrical energy transfer)}. \quad (26-26) \]

Moreover, this power \( P \) is also the rate at which energy is transferred from the battery to the unspecified device. If that device is a motor connected to a mechanical load, the energy is transferred as work done on the load. If the device is a storage battery that is being charged, the energy is transferred to stored chemical energy in the storage battery. If the device is a resistor, the energy is transferred to internal thermal energy, tending to increase the resistor’s temperature.
The unit of power that follows from Eq. 26-26 is the volt-ampere (V·A). We can write it as
\[ 1 \text{ V} \cdot \text{A} = \left( \frac{1 \text{ J}}{1 \text{ C}} \right) \left( \frac{1 \text{ C}}{1 \text{ s}} \right) = \frac{1 \text{ J}}{\text{s}} = 1 \text{ W}. \]

As an electron moves through a resistor at constant drift speed, its average kinetic energy remains constant and its lost electric potential energy appears as thermal energy in the resistor and the surroundings. On a microscopic scale, this energy transfer is due to collisions between the electron and the molecules of the resistor, which leads to an increase in the temperature of the resistor lattice. The mechanical energy thus transferred to thermal energy is dissipated (lost) because the transfer cannot be reversed.

For a resistor or some other device with resistance \( R \), we can combine Eqs. 26-8 (\( R = \frac{V}{i} \)) and 26-26 to obtain, for the rate of electrical energy dissipation due to a resistance, either

\[ P = i^2R \quad \text{(resistive dissipation)} \quad (26-27) \]

or

\[ P = \frac{V^2}{R} \quad \text{(resistive dissipation).} \quad (26-28) \]

**Caution:** We must be careful to distinguish these two equations from Eq. 26-26: \( P = iV \) applies to electrical energy transfers of all kinds; \( P = i^2R \) and \( P = \frac{V^2}{R} \) apply only to the transfer of electric potential energy to thermal energy in a device with resistance.

**Checkpoint 5**

A potential difference \( V \) is connected across a device with resistance \( R \), causing current \( i \) through the device. Rank the following variations according to the change in the rate at which electrical energy is converted to thermal energy due to the resistance, greatest change first: (a) \( V \) is doubled with \( R \) unchanged, (b) \( i \) is doubled with \( R \) unchanged, (c) \( R \) is doubled with \( V \) unchanged, (d) \( R \) is doubled with \( i \) unchanged.

**Sample Problem 26.06** Rate of energy dissipation in a wire carrying current

You are given a length of uniform heating wire made of a nickel–chromium–iron alloy called Nichrome; it has a resistance \( R \) of 72 Ω. At what rate is energy dissipated in each of the following situations? (1) A potential difference of 120 V is applied across the full length of the wire. (2) The wire is cut in half, and a potential difference of 120 V is applied across the length of each half.

**KEY IDEA**

Current in a resistive material produces a transfer of mechanical energy to thermal energy; the rate of transfer (dissipation) is given by Eqs. 26-26 to 26-28.

**Calculations:** Because we know the potential \( V \) and resistance \( R \), we use Eq. 26-28, which yields, for situation 1,

\[ P = \frac{V^2}{R} = \frac{(120 \text{ V})^2}{72 \text{ Ω}} = 200 \text{ W}. \quad \text{(Answer)} \]

In situation 2, the resistance of each half of the wire is \((72 \text{ Ω})/2\), or 36 Ω. Thus, the dissipation rate for each half is

\[ P' = \frac{(120 \text{ V})^2}{36 \text{ Ω}} = 400 \text{ W}, \]

and that for the two halves is

\[ P = 2P' = 800 \text{ W}. \quad \text{(Answer)} \]

This is four times the dissipation rate of the full length of wire. Thus, you might conclude that you could buy a heating coil, cut it in half, and reconnect it to obtain four times the heat output. Why is this unwise? (What would happen to the amount of current in the coil?)
Semiconductors

Semiconducting devices are at the heart of the microelectronic revolution that ushered in the information age. Table 26-2 compares the properties of silicon—a typical semiconductor—and copper—a typical metallic conductor. We see that silicon has many fewer charge carriers, a much higher resistivity, and a temperature coefficient of resistivity that is both large and negative. Thus, although the resistivity of copper increases with increasing temperature, that of pure silicon decreases.

Pure silicon has such a high resistivity that it is effectively an insulator and thus not of much direct use in microelectronic circuits. However, its resistivity can be greatly reduced in a controlled way by adding minute amounts of specific “impurity” atoms in a process called doping. Table 26-1 gives typical values of resistivity for silicon before and after doping with two different impurities.

We can roughly explain the differences in resistivity (and thus in conductivity) between semiconductors, insulators, and metallic conductors in terms of the energies of their electrons. (We need quantum physics to explain in more detail.) In a metallic conductor such as copper wire, most of the electrons are firmly locked in place within the atoms; much energy would be required to free them so they could move and participate in an electric current. However, there are also some electrons that, roughly speaking, are only loosely held in place and that require only little energy to become free. Thermal energy can supply that energy, as can an electric field applied across the conductor. The field would not only free these loosely held electrons but would also propel them along the wire; thus, the field would drive a current through the conductor.

In an insulator, significantly greater energy is required to free electrons so they can move through the material. Thermal energy cannot supply enough energy, and neither can any reasonable electric field applied to the insulator. Thus, no electrons are available to move through the insulator, and hence no current occurs even with an applied electric field.

A semiconductor is like an insulator except that the energy required to free some electrons is not quite so great. More important, doping can supply electrons or positive charge carriers that are very loosely held within the material and thus are easy to get moving. Moreover, by controlling the doping of a semiconductor, we can control the density of charge carriers that can participate in a current and thereby can control some of its electrical properties. Most semiconducting devices, such as transistors and junction diodes, are fabricated by the selective doping of different regions of the silicon with impurity atoms of different kinds.

Let us now look again at Eq. 26-22 for the resistivity of a conductor:

$$\rho = \frac{m}{e^2 n \tau}$$  \hspace{1cm} (26-29)

where $n$ is the number of charge carriers per unit volume and $\tau$ is the mean time between collisions of the charge carriers. The equation also applies to semiconductors. Let’s consider how $n$ and $\tau$ change as the temperature is increased.

In a conductor, $n$ is large but very nearly constant with any change in temperature. The increase of resistivity with temperature for metals (Fig. 26-10) is due to an increase in the collision rate of the charge carriers, which shows up in Eq. 26-29 as a decrease in $\tau$, the mean time between collisions.

<table>

<td>$-70 \times 10^{-3}$</td>
</tr>
</tbody>
</table>
In a semiconductor, $n$ is small but increases very rapidly with temperature as the increased thermal agitation makes more charge carriers available. This causes a decrease of resistivity with increasing temperature, as indicated by the negative temperature coefficient of resistivity for silicon in Table 26-2. The same increase in collision rate that we noted for metals also occurs for semiconductors, but its effect is swamped by the rapid increase in the number of charge carriers.

**Superconductors**

In 1911, Dutch physicist Kamerlingh Onnes discovered that the resistivity of mercury absolutely disappears at temperatures below about 4 K (Fig. 26-14). This phenomenon of superconductivity is of vast potential importance in technology because it means that charge can flow through a superconducting conductor without losing its energy to thermal energy. Currents created in a superconducting ring, for example, have persisted for several years without loss; the electrons making up the current require a force and a source of energy at start-up time but not thereafter.

Prior to 1986, the technological development of superconductivity was throttled by the cost of producing the extremely low temperatures required to achieve the effect. In 1986, however, new ceramic materials were discovered that become superconducting at considerably higher (and thus cheaper to produce) temperatures. Practical application of superconducting devices at room temperature may eventually become commonplace.

Superconductivity is a phenomenon much different from conductivity. In fact, the best of the normal conductors, such as silver and copper, cannot become superconducting at any temperature, and the new ceramic superconductors are actually good insulators when they are not at low enough temperatures to be in a superconducting state.

One explanation for superconductivity is that the electrons that make up the current move in coordinated pairs. One of the electrons in a pair may electrically distort the molecular structure of the superconducting material as it moves through, creating nearby a short-lived concentration of positive charge. The other electron in the pair may then be attracted toward this positive charge. According to the theory, such coordination between electrons would prevent them from colliding with the molecules of the material and thus would eliminate electrical resistance. The theory worked well to explain the pre-1986, lower temperature superconductors, but new theories appear to be needed for the newer, higher temperature superconductors.

**Review & Summary**

**Current** An electric current $i$ in a conductor is defined by

$$i = \frac{dq}{dt} \quad (26-1)$$

Here $dq$ is the amount of (positive) charge that passes in time $dt$ through a hypothetical surface that cuts across the conductor. By convention, the direction of electric current is taken as the direction in which positive charge carriers would move. The SI unit of electric current is the ampere (A): $1 \text{A} = 1 \text{C/s}$.

**Current Density** Current (a scalar) is related to current density $\vec{J}$ (a vector) by

$$i = \int \vec{J} \cdot d\vec{A}, \quad (26-4)$$

where $d\vec{A}$ is a vector perpendicular to a surface element of area $dA$ and the integral is taken over any surface cutting across the conductor. $\vec{J}$ has the same direction as the velocity of the moving charges if they are positive and the opposite direction if they are negative.

**Drift Speed of the Charge Carriers** When an electric field $\vec{E}$ is established in a conductor, the charge carriers (assumed positive) acquire a drift speed $v_d$ in the direction of $\vec{E}$; the velocity $\vec{v}_d$ is related to the current density by

$$\vec{J} = (ne)\vec{v}_d, \quad (26-7)$$

where $ne$ is the carrier charge density.

**Resistance of a Conductor** The resistance $R$ of a conductor is defined as

$$R = \frac{V}{i} \quad (\text{definition of } R), \quad (26-8)$$

where $V$ is the potential difference across the conductor and $i$ is the current. The SI unit of resistance is the ohm ($\Omega$): $1 \Omega = 1 \text{V/A}$. Similar equations define the resistivity $\rho$ and conductivity $\sigma$ of a material:

$$\rho = \frac{1}{\sigma} = \frac{E}{J} \quad (\text{definitions of } \rho \text{ and } \sigma), \quad (26-12, 26-10)$$
where $E$ is the magnitude of the applied electric field. The SI unit of resistivity is the ohm-meter ($\Omega \cdot \text{m}$). Equation 26-10 corresponds to the vector equation

$$\mathbf{E} = \rho \mathbf{J}.$$  \hfill (26-11)

The resistance $R$ of a conducting wire of length $L$ and uniform cross section is

$$R = \frac{\rho L}{A},$$  \hfill (26-16)

where $A$ is the cross-sectional area.

**Change of $\rho$ with Temperature** The resistivity $\rho$ for most materials changes with temperature. For many materials, including metals, the relation between $\rho$ and temperature $T$ is approximated by the equation

$$\rho - \rho_0 = \rho_0 \alpha (T - T_0).$$  \hfill (26-17)

Here $T_0$ is a reference temperature, $\rho_0$ is the resistivity at $T_0$, and $\alpha$ is the temperature coefficient of resistivity for the material.

**Ohm’s Law** A given device (conductor, resistor, or any other electrical device) obeys Ohm’s law if its resistance $R$, defined by Eq. 26-8 as $V/i$, is independent of the applied potential difference $V$. A given material obeys Ohm’s law if its resistivity, defined by Eq. 26-10, is independent of the magnitude and direction of the applied electric field $\mathbf{E}$.

**Resistivity of a Metal** By assuming that the conduction electrons in a metal are free to move like the molecules of a gas, it is possible to derive an expression for the resistivity of a metal:

$$\rho = \frac{m}{e^2 \pi^2}.$$  \hfill (26-22)

Here $n$ is the number of free electrons per unit volume and $\tau$ is the mean time between the collisions of an electron with the atoms of the metal. We can explain why metals obey Ohm’s law by pointing out that $\tau$ is essentially independent of the magnitude $E$ of any electric field applied to a metal.

**Power** The power $P$, or rate of energy transfer, in an electrical device across which a potential difference $V$ is maintained is

$$P = iV$$  \hfill (rate of electrical energy transfer).  \hfill (26-26)

**Resistive Dissipation** If the device is a resistor, we can write Eq. 26-26 as

$$P = i^2 R = \frac{V^2}{R}$$  \hfill (resistive dissipation).  \hfill (26-27, 26-28)

In a resistor, electric potential energy is converted to internal thermal energy via collisions between charge carriers and atoms.

**Semiconductors** Semiconductors are materials that have few conduction electrons but can become conductors when they are doped with other atoms that contribute charge carriers.

**Superconductors** Superconductors are materials that lose all electrical resistance at low temperatures. Some materials are superconducting at surprisingly high temperatures.

---

### Questions

1. Figure 26-15 shows cross sections through three long conductors of the same length and material, with square cross sections of edge lengths as shown. Conductor $B$ fits snugly within conductor $A$, and conductor $C$ fits snugly within conductor $B$. Rank the following according to their end-to-end resistances, greatest first: the individual conductors and the combinations of $A + B$ ($B$ inside $A$), $B + C$ ($C$ inside $B$), and $A + B + C$ ($B$ inside $A$ inside $C$).

![Figure 26-15](image1)

**Figure 26-15** Question 1.

2. Figure 26-16 shows cross sections through three wires of identical length and material; the sides are given in millimeters. Rank the wires according to their resistance (measured end to end along each wire’s length), greatest first.

![Figure 26-16](image2)

**Figure 26-16** Question 2.

3. Figure 26-17 shows a rectangular solid conductor of edge lengths $L, 2L,$ and $3L$. A potential difference $V$ is to be applied uniformly between pairs of opposite faces of the conductor as in Fig. 26-8b. (The potential difference is applied between the entire face on one side and the entire face on the other side.) First $V$ is applied between the left–right faces, then between the top–bottom faces, and then between the front–back faces. Rank those pairs, greatest first, according to the following (within the conductor): (a) the magnitude of the electric field, (b) the current density, (c) the current, and (d) the drift speed of the electrons.

![Figure 26-17](image3)

**Figure 26-17** Question 3.

4. Figure 26-18 shows plots of the current $i$ through a certain cross section of a wire over four different time periods. Rank the periods according to the net charge that passes through the cross section during the period, greatest first.

![Figure 26-18](image4)

**Figure 26-18** Question 4.
5 Figure 26-19 shows four situations in which positive and negative charges move horizontally and gives the rate at which each charge moves. Rank the situations according to the effective current through the regions, greatest first.

(a) $7 \text{ C/s}$
(b) $3 \text{ C/s}$
(c) $2 \text{ C/s}$
(d) $6 \text{ C/s}$

**Figure 26-19** Question 5.

6 In Fig. 26-20, a wire that carries a current consists of three sections with different radii. Rank the sections according to the following quantities, greatest first: (a) current, (b) magnitude of current density, and (c) magnitude of electric field.

7 Figure 26-21 gives the electric potential $V(x)$ versus position $x$ along a copper wire carrying current. The wire consists of three sections that differ in radius. Rank the three sections according to the magnitude of the (a) electric field and (b) current density, greatest first.

8 The following table gives the lengths of three copper rods, their diameters, and the potential differences between their ends. Rank the rods according to (a) the magnitude of the electric field within them, (b) the current density within them, and (c) the drift speed of electrons through them, greatest first.

9 Figure 26-22 gives the drift speed $v_d$ of conduction electrons in a copper wire versus position $x$ along the wire. The wire consists of three sections that differ in radius. Rank the three sections according to the following quantities, greatest first: (a) radius, (b) number of conduction electrons per cubic meter, (c) magnitude of electric field, (d) conductivity.

10 Three wires, of the same diameter, are connected in turn between two points maintained at a constant potential difference. Their resistivities and lengths are $\rho$ and $L$ (wire A), $1.2\rho$ and $1.2L$ (wire B), and $0.9\rho$ and $L$ (wire C). Rank the wires according to the rate at which energy is transferred to thermal energy within them, greatest first.

11 Figure 26-23 gives, for three wires of radius $R$, the current density $J(r)$ versus radius $r$, as measured from the center of a circular cross section through the wire. The wires are all made from the same material. Rank the wires according to the magnitude of the electric field (a) at the center, (b) halfway to the surface, and (c) at the surface, greatest first.

---

**Module 26-1 Electric Current**

1 During the 4.0 min a 5.0 A current is set up in a wire, how many (a) coulombs and (b) electrons pass through any cross section across the wire’s width?

2 An isolated conducting sphere has a 10 cm radius. One wire carries a current of 1.000 002 0 A into it. Another wire carries a current of 1.000 000 0 A out of it. How long would it take for the sphere to increase in potential by 1000 V?

3 A charged belt, 50 cm wide, travels at 30 m/s between a source of charge and a sphere. The belt carries charge into the sphere at a rate corresponding to 100 $\mu$A. Compute the surface charge density on the belt.

**Module 26-2 Current Density**

4 The (United States) National Electric Code, which sets maximum safe currents for insulated copper wires of various diameters, is given (in part) in the table. Plot the safe current density as a function of diameter. Which wire gauge has the maximum safe current density? (“Gauge” is a way of identifying wire diameters, and 1 mil = $10^{-3}$ in.)

5 A beam contains $2.0 \times 10^8$ doubly charged positive ions per cubic centimeter, all of which are moving north with a speed of $1.0 \times 10^5$ m/s. What are the (a) magnitude and (b) direction of the current density $\vec{J}$? (c) What additional quantity do you need to calculate the total current $i$ in this ion beam?

6 A certain cylindrical wire carries current. We draw a circle of radius $r$ around its central axis in Fig. 26-24 to determine the current $i$ within the circle. Figure 26-24b shows current $i$ as a function of $r^2$. The vertical scale is set by $i_0 = 4.0$ mA, and the
horizontal scale is set by \( r_1^2 = 4.0 \text{ mm}^2 \). (a) Is the current density uniform? (b) If so, what is its magnitude?

> A fuse in an electric circuit is a wire that is designed to melt, and thereby open the circuit, if the current exceeds a predetermined value. Suppose that the material to be used in a fuse melts when the current density rises to 440 A/cm². What diameter of cylindrical wire should be used to make a fuse that will limit the current to 0.50 A?

> A small but measurable current of \( 1.2 \times 10^{-10} \text{ A} \) exists in a copper wire whose diameter is 2.5 mm. The number of charge carriers per unit volume is \( 8.49 \times 10^{28} \text{ m}^{-3} \). Assuming the current is uniform, calculate the (a) current density and (b) electron drift speed.

> The magnitude \( J(r) \) of the current density in a certain cylindrical wire is given as a function of radial distance from the center of the wire’s cross section as \( J(r) = Br \), where \( r \) is in meters, \( B \) is in amperes per square meter, and \( B = 2.00 \times 10^5 \text{ A/m}^2 \). This function applies out to the wire’s radius of 2.00 mm. How much current is contained within the width of a thin ring concentric with the wire if the ring has a radial width of 10.0 \( \mu \text{m} \) and is at a radial distance of 1.20 mm?

> The magnitude \( J(r) \) of the current density in a certain lab wire with a circular cross section of radius \( R = 2.00 \text{ mm} \) is given by \( J = (3.00 \times 10^8 \text{ A})/r^2 \), with \( J \) in amperes per square meter and radial distance \( r \) in meters. What is the current through the outer section bounded by \( r = 0.900R \) and \( r = R \)?

> What is the current in a wire of radius \( R = 3.40 \text{ mm} \) if the magnitude of the current density is given by (a) \( J_r = J_0/r^2 \) and (b) \( J_r = J_0(1-r/R) \), in which \( r \) is the radial distance and \( J_0 = 5.50 \times 10^4 \text{ A/m}^2 \)? (c) Which function maximizes the current density near the wire’s surface?

> Near Earth, the density of protons in the solar wind (a stream of particles from the Sun) is 8.70 \( \text{ cm}^{-3} \), and their speed is 470 km/s. (a) Find the current density of these protons. (b) If Earth’s magnetic field did not deflect the protons, what total current would Earth receive?

> How long does it take electrons to get from a car battery to the starting motor? Assume the current is 300 A and the electrons travel through a copper wire with a cross-sectional area 0.21 \( \text{ cm}^2 \) and length 0.85 m. The number of charge carriers per unit volume is \( 8.49 \times 10^{28} \text{ m}^{-3} \).

### Module 26.3 Resistance and Resistivity

> A human being can be electrocuted if a current as small as 50 mA passes near the heart. An electrician working with sweaty hands makes good contact with the two conductors he is holding, one in each hand. If his resistance is 2000 \( \Omega \), what might the fatal voltage be?

> A coil is formed by winding 250 turns of insulated 16-gauge copper wire (diameter = 1.3 mm) in a single layer on a cylindrical form of radius 12 cm. What is the resistance of the coil? Neglect the thickness of the insulation. (Use Table 26-1.)

> Copper and aluminum are being considered for a high-voltage transmission line that must carry a current of 60.0 A. The resistance per unit length is to be 0.150 \( \Omega/\text{km} \). The densities of copper and aluminum are 8960 and 2600 kg/m³, respectively. Compute (a) the magnitude \( J \) of the current density and (b) the mass per unit length \( \lambda \) for a copper cable and (c) \( J \) and (d) \( \lambda \) for an aluminum cable.

> A wire of Nichrome (a nickel–chromium–iron alloy commonly used in heating elements) is 1.0 m long and 1.0 mm² in cross-sectional area. It carries a current of 4.0 A when a 2.0 V potential difference is applied between its ends. Calculate the conductivity \( \sigma \) of Nichrome.

> A wire 4.00 m long and 6.00 mm in diameter has a resistance of 15.0 mΩ. A potential difference of 23.0 V is applied between the ends. (a) What is the current in the wire? (b) What is the magnitude of the current density? (c) Calculate the resistivity of the wire material. (d) Using Table 26-1, identify the material.

> What is the resistivity of a wire of 1.0 mm diameter, 2.0 m length, and 50 mΩ resistance?

> A certain wire has a resistance \( R \). What is the resistance of a second wire, made of the same material, that is half as long and has half the diameter?

> A common flashlight bulb is rated at 0.30 A and 2.9 V (the values of the current and voltage under operating conditions). If the resistance of the tungsten bulb filament at room temperature (20°C) is 1.1 Ω, what is the temperature of the filament when the bulb is on?

**Kiting during a storm.** The legend that Benjamin Franklin flew a kite as a storm approached is only a legend—he was neither stupid nor suicidal. Suppose a kite string of radius 2.00 mm extends directly upward by 0.800 km and is coated with a 0.500 mm layer of water having resistivity 150 Ω·m. If the potential difference between the two ends of the string is 160 MV, what is the current through the water layer? The danger is not this current but the chance that the string draws a lightning strike, which can have a current as large as 500 000 A (way beyond just being lethal).

> When 115 V is applied across a wire that is 10 m long and has a 0.30 mm radius, the magnitude of the current density is \( 1.4 \times 10^8 \text{ A/m}^2 \). Find the resistivity of the wire.

> Figure 26-25a gives the magnitude \( E(x) \) of the electric fields that have been set up by a battery along a resistive rod of length 9.00 mm (Fig. 26-25b). The vertical scale is set by \( E_a = 4.00 \times 10^3 \text{ V/m} \). The rod consists of three sections of the same material but with different radii. (The schematic diagram of Fig. 26-25b does not indicate the different radii.) The radius of section 3 is 2.00 mm. What is the radius of (a) section 1 and (b) section 2?

> A wire with a resistance of 6.0 Ω is drawn out through a die so that its new length is three times its original length. Find the resistance of the longer wire, assuming that the resistivity and density of the material are unchanged.

> In Fig. 26-26a, a 9.00 V battery is connected to a resistive strip that consists of three sections with the same cross-sectional areas but different conductivities. Figure 26-26b gives the electric.
potential \( V(x) \) versus position \( x \) along the strip. The horizontal scale is set by \( x_s = 8.00 \text{ mm} \). Section 3 has conductivity \( 3.00 \times 10^7 \text{ (}\Omega\cdot\text{m})^{-1} \). What is the conductivity of section (a) 1 and (b) 2?

![Figure 26-26 Problem 26.](image)

27. Two conductors are made of the same material and have the same length. Conductor \( A \) is a solid wire of diameter 1.0 mm. Conductor \( B \) is a hollow tube of outside diameter 2.0 mm and inside diameter 1.0 mm. What is the resistance ratio \( R_A/R_B \), measured between their ends?

28. Figure 26-27 gives the electric potential \( V(x) \) along a copper wire carrying uniform current, from a point of higher potential \( V_i = 12.0 \mu\text{V} \) at \( x = 0 \) to a point of zero potential at \( x_s = 3.00 \text{ mm} \). The wire has a radius of 2.00 mm. What is the current in the wire?

29. A potential difference of 3.00 nV is set up across a 2.00 cm length of copper wire that has a radius of 2.00 mm. How much charge drifts through a cross section in 3.00 ms?

30. If the gauge number of a wire is increased by 6, the diameter is halved; if a gauge number is increased by 1, the diameter decreases by the factor \([2^{1/6}] \) (see the table in Problem 4). Knowing this, and knowing that 1000 ft of 10-gauge copper wire has a resistance of approximately 1.00 \( \Omega \), estimate the resistance of 25 ft of 22-gauge copper wire.

31. An electrical cable consists of 125 strands of fine wire, each having 2.65 \( \mu\Omega \) resistance. The same potential difference is applied between the ends of all the strands and results in a total current of 0.750 A. (a) What is the current in each strand? (b) What is the applied potential difference? (c) What is the resistance of the cable?

32. Earth's lower atmosphere contains negative and positive ions that are produced by radioactive elements in the soil and cosmic rays from space. In a certain region, the atmospheric electric field strength is 120 V/m and the field is directed vertically down. This field causes singly charged positive ions, at a density of 620 cm\(^{-3} \), to drift downward and singly charged negative ions, at a density of 550 cm\(^{-3} \), to drift upward (Fig. 26-28). The measured conductivity of the air in that region is \( 2.70 \times 10^{-14} \text{ (}\Omega\cdot\text{m})^{-1} \). Calculate (a) the magnitude of the current density and (b) the ion drift speed, assumed to be the same for positive and negative ions.

33. A block in the shape of a rectangular solid has a cross-sectional area of 3.50 cm\(^2\) across its width, a front-to-rear length of 15.8 cm, and a resistance of 935 \( \Omega \). The block's material contains \( 5.33 \times 10^{22} \) conduction electrons/m\(^3\). A potential difference of 35.8 V is maintained between its front and rear faces. (a) What is the current in the block? (b) If the current density is uniform, what is its magnitude? What are (c) the drift velocity of the conduction electrons and (d) the magnitude of the electric field in the block?

34. Figure 26-29 shows wire section 1 of diameter \( D_1 = 4.00\text{R} \) and wire section 2 of diameter \( D_2 = 2.00\text{R} \), connected by a tapered section. The wire is copper and carries a current. Assume that the current is uniformly distributed across any cross-sectional area through the wire’s width. The electric potential change \( V \) along the length \( L = 2.00 \text{ m} \) shown in section 2 is 10.0 \( \mu\text{V} \). The number of charge carriers per unit volume is \( 8.49 \times 10^{26} \) electrons/m\(^3\). What is the drift speed of the conduction electrons in section 1?

35. In Fig. 26-30, current is set up through a truncated right circular cone of resistivity 731 \( \Omega\cdot\text{m} \), left radius \( a = 2.00 \text{ mm} \), right radius \( b = 2.30 \text{ mm} \), and length \( L = 1.94 \text{ cm} \). Assume that the current density is uniform across any cross section taken perpendicular to the length. What is the resistance of the cone?

36. Swimming during a storm. Figure 26-31 shows a swimmer at distance \( D = 35.0 \text{ m} \) from a lightning strike to the water, with current \( I = 78 \text{ kA} \). The water has resistivity 30 \( \Omega\cdot\text{m} \), the width of the swimmer along a radial line from the strike is 0.70 m, and his resistance across that width is 4.00 k\( \Omega \). Assume that the current spreads through the water over a hemisphere centered on the strike point. What is the current through the swimmer?

Module 26-4 Ohm’s Law

37. Show that, according to the free-electron model of electrical conduction in metals and classical physics, the resistivity of metals should be proportional to \( \sqrt{T} \), where \( T \) is the temperature in kelvins. (See Eq. 19-31.)
Module 26-5  Power, Semiconductors, Superconductors

38 In Fig. 26-32a, a 20 Ω resistor is connected to a battery. Figure 26-32b shows the increase of thermal energy $E_{th}$ in the resistor as a function of time $t$. The vertical scale is set by $E_{th,s} = 2.50 \text{ mJ}$, and the horizontal scale is set by $t_s = 4.0 \text{ s}$. What is the electric potential across the battery?

![Figure 26-32 Problem 38.](image)

39 A certain brand of hot-dog cooker works by applying a potential difference of 120 V across opposite ends of a hot dog and allowing it to cook by means of the thermal energy produced. The current is 10.0 A, and the energy required to cook one hot dog is 60.0 kJ. If the rate at which energy is supplied is unchanged, how long will it take to cook three hot dogs simultaneously?

![Figure 26-33 Problem 42.](image)

40 Thermal energy is produced in a resistor at a rate of 100 W when the current is 3.00 A. What is the resistance?

41 SSM A 120 V potential difference is applied to a space heater whose resistance is 14 Ω when hot. (a) At what rate is electrical energy transferred to thermal energy? (b) What is the cost for 5.0 h at US$0.05/kW·h?

42 In Fig. 26-33, a battery of potential difference $V = 12 \text{ V}$ is connected to a resistive strip of resistance $R = 6.0 \text{ Ω}$. When an electron moves through the strip from one end to the other, (a) in which direction in the figure does the electron move, (b) how much work is done on the electron by the electric field in the strip, and (c) how much energy is transferred to the thermal energy of the strip by the electron?

![Figure 26-34 Problem 50.](image)

43 ILW An unknown resistor is connected between the terminals of a 3.00 V battery. Energy is dissipated in the resistor at the rate of 0.540 W. The same resistor is then connected between the terminals of a 1.50 V battery. At what rate is energy now dissipated?

44 A student kept his 9.0 V, 7.0 W radio turned on at full volume from 9:00 P.M. until 2:00 A.M. How much charge went through it?

45 SSM ILW A 1250 W radiant heater is constructed to operate at 115 V. (a) What is the current in the heater when the unit is operating? (b) What is the resistance of the heating coil? (c) How much thermal energy is produced in 1.0 h?

46 A copper wire of cross-sectional area $2.00 \times 10^{-6} \text{ m}^2$ and length 4.00 m has a current of 2.00 A uniformly distributed across that area. (a) What is the magnitude of the electric field along the wire? (b) How much electrical energy is transferred to thermal energy in 30 min?

47 A heating element is made by maintaining a potential difference of 75.0 V across the length of a Nichrome wire that has a $2.60 \times 10^{-6} \text{ m}^2$ cross section. Nichrome has a resistivity of $5.00 \times 10^{-7} \text{ Ω}·\text{m}$. (a) If the element dissipates 5000 W, what is its length? (b) If 100 V is used to obtain the same dissipation rate, what should the length be?

48 Exploding shoes. The rain-soaked shoes of a person may explode if ground current from nearby lightning vaporizes the water. The sudden conversion of water to water vapor causes a dramatic expansion that can rip apart shoes. Water has density 1000 kg/m³ and requires 2256 kJ/kg to be vaporized. If horizontal current lasts 2.00 ms and encounters water with resistivity 150 Ω·m, length 12.0 cm, and vertical cross-sectional area $15 \times 10^{-5} \text{ m}^2$, what average current is required to vaporize the water?

49 A 100 W lightbulb is plugged into a standard 120 V outlet. (a) How much does it cost per 31-day month to leave the light turned on continuously? Assume electrical energy costs US$0.06/kW·h. (b) What is the resistance of the bulb? (c) What is the current in the bulb?

50 SSM The current through the battery and resistors 1 and 2 in Fig. 26-34a is 2.00 A. Energy is transferred from the current to thermal energy $E_{th}$ in both resistors. Curves 1 and 2 in Fig. 26-34b give that thermal energy $E_{th}$ for resistors 1 and 2, respectively, as a function of time $t$. The vertical scale is set by $E_{th,s} = 40.0 \text{ mJ}$, and the horizontal scale is set by $t_s = 5.00 \text{ s}$. What is the power of the battery?

51 SSM WWW Wire C and wire D are made from different materials and have length $L_C = L_D = 1.0 \text{ m}$. The resistivity and diameter of wire C are $2.0 \times 10^{-6} \text{ Ω}·\text{m}$ and 1.00 mm, and those of wire D are $1.0 \times 10^{-6} \text{ Ω}·\text{m}$ and 0.50 mm. The wires are joined as shown in Fig. 26-35, and a current of 2.0 A is set up in them. What is the electric potential difference between (a) points 1 and 2 and (b) points 2 and 3? What is the rate at which energy is dissipated between (c) points 1 and 2 and (d) points 2 and 3?

52 SSM The current-density magnitude in a certain circular wire is $J = (2.75 \times 10^{10} \text{ A/m}^2)r^{2}$, where $r$ is the radial distance out to the wire’s radius of 3.00 mm. The potential applied to the wire (end to end) is 60.0 V. How much energy is converted to thermal energy in 1.00 h?

53 A 120 V potential difference is applied to a space heater that dissipates 500 W during operation. (a) What is its resistance during operation? (b) At what rate do electrons flow through any cross section of the heater element?
**Additional Problems**

54 SSM Figure 26-36a shows a rod of resistive material. The resistance per unit length of the rod increases in the positive direction of the x axis. At any position \( x \) along the rod, the resistance \( dR \) of a narrow (differential) section of width \( dx \) is given by \( dR = 5.00x \), where \( dR \) is in ohms and \( x \) is in meters. Figure 26-36b shows such a narrow section. You are to slice off a length of the rod between \( x = 0 \) and some position \( x = L \) and then connect that length to a battery with potential difference \( V = 5.00 \) V (Fig. 26-36c). You want the current in the length to transfer energy to thermal energy at the rate of 200 W. At what position \( x = L \) should you cut the rod?

55 SSM A Nichrome heater dissipates 500 W when the applied potential difference is 110 V and the wire temperature is 800°C. What would be the dissipation rate if the wire temperature were held at 200°C by immersing the wire in a bath of cooling oil? The applied potential difference remains the same, and \( \alpha \) for Nichrome at 800°C is \( 4.0 \times 10^{-4} \) K\(^{-1} \).

56 A potential difference of 1.20 V will be applied to a 33.0 m length of 18-gauge copper wire (diameter = 0.0400 in.). Calculate (a) the current, (b) the magnitude of the current density, (c) the magnitude of the electric field within the wire, and (d) the rate at which thermal energy will appear in the wire.

57 An 18.0 W device has 9.00 V across it. How much charge goes through the device in 4.00 h?

58 An aluminum rod with a square cross section is 1.3 m long and 5.2 mm on edge. (a) What is the resistance between its ends? (b) What must be the diameter of a cylindrical copper rod of length 1.3 m if its resistance is to be the same as that of the aluminum rod?

59 A cylindrical metal rod is 1.60 m long and 5.50 mm in diameter. The resistance between its two ends (at 20°C) is \( 1.09 \times 10^{-3} \) Ω. (a) What is the material? (b) A round disk, 2.00 cm in diameter and 1.00 mm thick, is formed of the same material. What is the resistance between the round faces, assuming that each face is an equipotential surface?

60 The chocolate crumb mystery. This story begins with Problem 60 in Chapter 23 and continues through Chapters 24 and 25. The chocolate crumb powder moved to the silo through a pipe of radius \( R \) with uniform speed \( v \) and uniform charge density \( \rho \). (a) Find an expression for the current \( i \) (the rate at which charge on the powder moved) through a perpendicular cross section of the pipe. (b) Evaluate \( i \) for the conditions at the factory: pipe radius \( R = 5.0 \) cm, speed \( v = 2.0 \) m/s, and charge density \( \rho = 1.1 \times 10^{-3} \) C/m\(^2\). If the powder were to flow through a change \( V \) in electric potential, its energy could be transferred to a spark at the rate \( P = iV \). (c) Could there be such a transfer within the pipe due to the radial potential difference discussed in Problem 70 of Chapter 24?

As the powder flowed from the pipe into the silo, the electric potential of the powder changed. The magnitude of that change was at least equal to the radial potential difference within the pipe (as evaluated in Problem 70 of Chapter 24). (d) Assuming that value for the potential difference and using the current found in (b) above, find the rate at which energy could have been transferred from the powder to a spark as the powder exited the pipe. (e) If a spark did occur at the exit and lasted for 0.20 s (a reasonable expectation), how much energy would have been transferred to the spark? Recall from Problem 60 in Chapter 23 that a minimum energy transfer of 150 mJ is needed to cause an explosion. (f) Where did the powder explosion most likely occur: in the powder cloud at the unloading bin (Problem 60 of Chapter 25), within the pipe, or at the exit of the pipe into the silo?

61 SSM A steady beam of alpha particles \( (q = +2e) \) traveling with constant kinetic energy 20 MeV carries a current of 0.25 μA. (a) If the beam is directed perpendicular to a flat surface, how many alpha particles strike the surface in 3.0 s? (b) At any instant, how many alpha particles are there in a given 20 cm length of the beam? (c) Through what potential difference is it necessary to accelerate each alpha particle from rest to bring it to an energy of 20 MeV?

62 A resistor with a potential difference of 200 V across it transfers electrical energy to thermal energy at the rate of 5000 W. What is the resistance of the resistor?

63 A 2.0 kW heater element from a dryer has a length of 80 cm. If a 10 cm section is removed, what power is used by the now shortened element at 120 V?

64 A cylindrical resistor of radius 5.0 mm and length 2.0 cm is made of material that has a resistivity of \( 3.5 \times 10^{-8} \) Ω·m. What are (a) the magnitude of the current density and (b) the potential difference when the energy dissipation rate in the resistor is 1.0 W?

65 A potential difference \( V \) is applied to a wire of cross-sectional area \( A \), length \( L \), and resistivity \( \rho \). You want to change the applied potential difference and stretch the wire so that the energy dissipation rate is multiplied by 30.0 and the current is multiplied by 4.00. Assuming the wire’s density does not change, what are (a) the ratio of the new length to \( L \) and (b) the ratio of the new cross-sectional area to \( A \)?

66 The headlights of a moving car require about 10 A from the 12 V alternator, which is driven by the engine. Assume the alternator is 80% efficient (its output electrical power is 80% of its input mechanical power), and calculate the horsepower the engine must supply to run the lights.

67 A 500 W heating unit is designed to operate with an applied potential difference of 115 V. (a) By what percentage will its heat output drop if the applied potential difference drops to 110 V? Assume no change in resistance. (b) If you took the variation of resistance with temperature into account, would the actual drop in heat output be larger or smaller than that calculated in (a)?

68 The copper windings of a motor have a resistance of 50 Ω at 20°C when the motor is idle. After the motor has run for several hours, the resistance rises to 58 Ω. What is the temperature of the windings now? Ignore changes in the dimensions of the windings. (Use Table 26-1.)

69 How much electrical energy is transferred to thermal energy in 2.00 h by an electrical resistance of 400 Ω when the potential applied across it is 90.0 V?

70 A caterpillar of length 4.0 cm crawls in the direction of electron drift along a 5.2-mm-diameter bare copper wire that carries a uniform current of 12 A. (a) What is the potential difference between the two ends of the caterpillar? (b) Is its tail positive or negative relative to its head? (c) How much time does the caterpillar take to crawl 1.0 cm if it crawls at the drift speed of the electrons in the wire? (The number of charge carriers per unit volume is \( 8.49 \times 10^{29} \) m\(^{-3}\).)

71 SSM (a) At what temperature would the resistance of a copper conductor be double its resistance at 20.0°C? (Use 20.0°C as the reference point in Eq. 26-17; compare your answer with
Fig. 26-10.) (b) Does this same “doubling temperature” hold for all copper conductors, regardless of shape or size?

73 A coil of current-carrying Nichrome wire is immersed in a liquid. (Nichrome is a nickel–chromium–iron alloy commonly used in heating elements.) When the potential difference across the coil is 12 V and the current through the coil is 5.2 A, the liquid evaporates at the steady rate of 21 mg/s. Calculate the heat of vaporization of the liquid (see Module 18-4).

74 The current density in a wire is uniform and has magnitude \( 2.0 \times 10^6 \text{ A/m}^2 \), the wire’s length is 5.0 m, and the density of conduction electrons is \( 8.49 \times 10^{28} \text{ m}^{-3} \). How long does an electron take (on the average) to travel the length of the wire?

75 A certain x-ray tube operates at a current of 7.00 mA and a potential difference of 80.0 kV. What is its power in watts?

76 A current is established in a gas discharge tube when a sufficiently high potential difference is applied across the two electrodes in the tube. The gas ionizes; electrons move toward the positive terminal and singly charged positive ions toward the negative terminal. (a) What is the current in a hydrogen discharge tube in which \( 3.1 \times 10^{18} \) electrons and \( 1.1 \times 10^{18} \) protons move past a cross-sectional area of the tube each second? (b) Is the direction of the current density \( \vec{J} \) toward or away from the negative terminal?

77 In Fig. 26-37, a resistance coil, wired to an external battery, is placed inside a thermally insulated cylinder fitted with a frictionless piston and containing an ideal gas. A current \( i = 240 \text{ mA} \) flows through the coil, which has a resistance \( R = 550 \text{ \Omega} \). At what speed \( v \) must the piston, of mass \( m = 12 \text{ kg} \), move upward in order that the temperature of the gas remains unchanged?

78 An insulating belt moves at speed \( 30 \text{ m/s} \) and has a width of 50 cm. It carries charge into an experimental device at a rate corresponding to 100 \( \mu \text{A} \). What is the surface charge density on the belt?

79 In a hypothetical fusion research lab, high temperature helium gas is completely ionized and each helium atom is separated into two free electrons and the remaining positively charged nucleus, which is called an alpha particle. An applied electric field causes the alpha particles to drift to the east at 25.0 m/s while the electrons drift to the west at 88.0 m/s. The alpha particle density is \( 2.80 \times 10^{15} \text{ cm}^{-3} \). What are (a) the net current density and (b) the current direction?

80 When a metal rod is heated, not only its resistance but also its length and cross-sectional area change. The relation \( R = \rho L/A \) suggests that all three factors should be taken into account in measuring \( \rho \) at various temperatures. If the temperature changes by 1.0°C, what percentage changes in (a) \( L \), (b) \( A \), and (c) \( R \) occur for a copper conductor? (d) What conclusion do you draw? The coefficient of linear expansion is \( 1.70 \times 10^{-5} \text{ K}^{-1} \).

81 A beam of 16 MeV deuterons from a cyclotron strikes a copper block. The beam is equivalent to current of 15 \( \mu \text{A} \). (a) At what rate do deuterons strike the block? (b) At what rate is thermal energy produced in the block?

82 A linear accelerator produces a pulsed beam of electrons. The pulse current is 0.50 A, and the pulse duration is 0.10 \( \mu \text{s} \). (a) How many electrons are accelerated per pulse? (b) What is the average current for a machine operating at 500 pulses/s? If the electrons are accelerated to an energy of 50 MeV, what are the (c) average power and (d) peak power of the accelerator?

83 An electric immersion heater normally takes 100 min to bring cold water in a well-insulated container to a certain temperature, after which a thermostat switches the heater off. One day the line voltage is reduced by 6.00% because of a laboratory overload. How long does heating the water now take? Assume that the resistance of the heating element does not change.

84 A 400 W immersion heater is placed in a pot containing 2.00 L of water at 20°C. (a) How long will the water take to rise to the boiling temperature, assuming that 80% of the available energy is absorbed by the water? (b) How much longer is required to evaporate half of the water?

85 A 30 \( \mu \text{F} \) capacitor is connected across a programmed power supply. During the interval from \( t = 0 \) to \( t = 3.00 \text{ s} \) the output voltage of the supply is given by \( V(t) = 6.00 + 4.00t - 2.00t^2 \text{ volts} \). At \( t = 0.500 \text{ s} \) find (a) the charge on the capacitor, (b) the current into the capacitor, and (c) the power output from the power supply.
CHAPTER 27

Circuits

27-1 SINGLE-LOOP CIRCUITS

Learning Objectives

After reading this module, you should be able to . . .

27.01 Identify the action of an emf source in terms of the work it does.
27.02 For an ideal battery, apply the relationship between the emf, the current, and the power (rate of energy transfer).
27.03 Draw a schematic diagram for a single-loop circuit containing a battery and three resistors.
27.04 Apply the loop rule to write a loop equation that relates the potential differences of the circuit elements around a (complete) loop.
27.05 Apply the resistance rule in crossing through a resistor.
27.06 Apply the emf rule in crossing through an emf.
27.07 Identify that resistors in series have the same current, which is the same value that their equivalent resistor has.
27.08 Calculate the equivalent of series resistors.
27.09 Identify that a potential applied to resistors wired in series is equal to the sum of the potentials across the individual resistors.
27.10 Calculate the potential difference between any two points in a circuit.
27.11 Distinguish a real battery from an ideal battery and, in a circuit diagram, replace a real battery with an ideal battery and an explicitly shown resistance.
27.12 With a real battery in a circuit, calculate the potential difference between its terminals for current in the direction of the emf and in the opposite direction.
27.13 Identify what is meant by grounding a circuit, and draw a schematic diagram for such a connection.
27.14 Identify that grounding a circuit does not affect the current in a circuit.
27.15 Calculate the dissipation rate of energy in a real battery.
27.16 Calculate the net rate of energy transfer in a real battery for current in the direction of the emf and in the opposite direction.

Key Ideas

- An emf device does work on charges to maintain a potential difference between its output terminals. If \( dW \) is the work the device does to force positive charge \( dq \) from the negative to the positive terminal, then the emf (work per unit charge) of the device is
  \[
  \varepsilon = \frac{dW}{dq} \quad \text{(definition of \( \varepsilon \)).}
  \]
- An ideal emf device is one that lacks any internal resistance. The potential difference between its terminals is equal to the emf.
- A real emf device has internal resistance. The potential difference between its terminals is equal to the emf only if there is no current through the device.
- The change in potential in traversing a resistance \( R \) in the direction of the current is \(-iR\); in the opposite direction it is \(+iR\) (resistance rule).
- The change in potential in traversing an ideal emf device in the direction of the emf arrow is \(+\varepsilon\); in the opposite direction it is \(-\varepsilon\) (emf rule).
- Conservation of energy leads to the loop rule: Loop Rule. The algebraic sum of the changes in potential encountered in a complete traversal of any loop of a circuit must be zero.

Conservation of charge leads to the junction rule (Chapter 26):

Junction Rule. The sum of the currents entering any junction must be equal to the sum of the currents leaving that junction.

- When a real battery of emf \( \varepsilon \) and internal resistance \( r \) does work on the charge carriers in a current \( i \) through the battery, the rate \( P \) of energy transfer to the charge carriers is
  \[
  P = iV,
  \]
  where \( V \) is the potential across the terminals of the battery.
- The rate \( P \) at which energy is dissipated as thermal energy in the battery is
  \[
  P_r = i^2r.
  \]
- The rate \( P_{\text{emf}} \) at which the chemical energy in the battery changes is
  \[
  P_{\text{emf}} = i\varepsilon.
  \]
- When resistances are in series, they have the same current. The equivalent resistance that can replace a series combination of resistances is
  \[
  R_{\text{eq}} = \sum_{j=1}^{n} R_j \quad (n \text{ resistances in series}).
  \]
What Is Physics?

You are surrounded by electric circuits. You might take pride in the number of electrical devices you own and might even carry a mental list of the devices you wish you owned. Every one of those devices, as well as the electrical grid that powers your home, depends on modern electrical engineering. We cannot easily estimate the current financial worth of electrical engineering and its products, but we can be certain that the financial worth continues to grow yearly as more and more tasks are handled electrically. Radios are now tuned electronically instead of manually. Messages are now sent by email instead of through the postal system. Research journals are now read on a computer instead of in a library building, and research papers are now copied and filed electronically instead of photocopied and tucked into a filing cabinet. Indeed, you may be reading an electronic version of this book.

The basic science of electrical engineering is physics. In this chapter we cover the physics of electric circuits that are combinations of resistors and batteries (and, in Module 27-4, capacitors). We restrict our discussion to circuits through which charge flows in one direction, which are called either direct-current circuits or DC circuits. We begin with the question: How can you get charges to flow?

“Pumping” Charges

If you want to make charge carriers flow through a resistor, you must establish a potential difference between the ends of the device. One way to do this is to connect each end of the resistor to one plate of a charged capacitor. The trouble with this scheme is that the flow of charge acts to discharge the capacitor, quickly bringing the plates to the same potential. When that happens, there is no longer an electric field in the resistor, and thus the flow of charge stops.

To produce a steady flow of charge, you need a “charge pump,” a device that—by doing work on the charge carriers—maintains a potential difference between a pair of terminals. We call such a device an emf device, and the device is said to provide an emf \( \mathcal{E} \), which means that it does work on charge carriers. An emf device is sometimes called a seat of emf. The term emf comes from the outdated phrase electromotive force, which was adopted before scientists clearly understood the function of an emf device.

In Chapter 26, we discussed the motion of charge carriers through a circuit in terms of the electric field set up in the circuit—the field produces forces that move the charge carriers. In this chapter we take a different approach: We discuss the motion of the charge carriers in terms of the required energy—an emf device supplies the energy for the motion via the work it does.

A common emf device is the battery, used to power a wide variety of machines from wristwatches to submarines. The emf device that most influences our daily lives, however, is the electric generator, which, by means of electrical connections (wires) from a generating plant, creates a potential difference in our homes and workplaces. The emf devices known as solar cells, long familiar as the wing-like panels on spacecraft, also dot the countryside for domestic applications. Less familiar emf devices are the fuel cells that powered the space shuttles and the thermopiles that provide onboard electrical power for some spacecraft and for remote stations in Antarctica and elsewhere. An emf device does not have to be an instrument—living systems, ranging from electric eels and human beings to plants, have physiological emf devices.

Although the devices we have listed differ widely in their modes of operation, they all perform the same basic function—they do work on charge carriers and thus maintain a potential difference between their terminals.
Work, Energy, and Emf

Figure 27-1 shows an emf device (consider it to be a battery) that is part of a simple circuit containing a single resistance $R$ (the symbol for resistance and a resistor is $\ell$). The emf device keeps one of its terminals (called the positive terminal and often labeled $+$) at a higher electric potential than the other terminal (called the negative terminal and labeled $-$). We can represent the emf of the device with an arrow that points from the negative terminal toward the positive terminal as in Fig. 27-1. A small circle on the tail of the emf arrow distinguishes it from the arrows that indicate current direction.

When an emf device is not connected to a circuit, the internal chemistry of the device does not cause any net flow of charge carriers within it. However, when it is connected to a circuit as in Fig. 27-1, its internal chemistry causes a net flow of positive charge carriers from the negative terminal to the positive terminal, in the direction of the emf arrow. This flow is part of the current that is set up around the circuit in that same direction (clockwise in Fig. 27-1).

Within the emf device, positive charge carriers move from a region of low electric potential and thus low electric potential energy (at the negative terminal) to a region of higher electric potential and higher electric potential energy (at the positive terminal). This motion is just the opposite of what the electric field between the terminals (which is directed from the positive terminal toward the negative terminal) would cause the charge carriers to do.

Thus, there must be some source of energy within the device, enabling it to do work on the charges by forcing them to move as they do. The energy source may be chemical, as in a battery or a fuel cell. It may involve mechanical forces, as in an electric generator. Temperature differences may supply the energy, as in a thermopile; or the Sun may supply it, as in a solar cell.

Let us now analyze the circuit of Fig. 27-1 from the point of view of work and energy transfers. In any time interval $dt$, a charge $dq$ passes through any cross section of this circuit, such as $aa'$. This same amount of charge must enter the emf device at its low-potential end and leave at its high-potential end. The device must do an amount of work $dW$ on the charge $dq$ to force it to move in this way.

We define the emf of the emf device in terms of this work:

$$\varepsilon = \frac{dW}{dq} \quad \text{(definition of $\varepsilon$).}$$  \hspace{1cm} (27-1)

In words, the emf of an emf device is the work per unit charge that the device does in moving charge from its low-potential terminal to its high-potential terminal. The SI unit for emf is the joule per coulomb; in Chapter 24 we defined that unit as the volt.

An ideal emf device is one that lacks any internal resistance to the internal movement of charge from terminal to terminal. The potential difference between the terminals of an ideal emf device is equal to the emf of the device. For example, an ideal battery with an emf of 12.0 V always has a potential difference of 12.0 V between its terminals.

A real emf device, such as any real battery, has internal resistance to the internal movement of charge. When a real emf device is not connected to a circuit, and thus does not have current through it, the potential difference between its terminals is equal to its emf. However, when that device has current through it, the potential difference between its terminals differs from its emf. We shall discuss such real batteries near the end of this module.

When an emf device is connected to a circuit, the device transfers energy to the charge carriers passing through it. This energy can then be transferred from the charge carriers to other devices in the circuit, for example, to light a bulb. Figure 27-2a shows a circuit containing two ideal rechargeable (storage) batteries A and B, a resistance $R$, and an electric motor M that can lift an object by using

![Figure 27-2](image-url)
energy it obtains from charge carriers in the circuit. Note that the batteries are connected so that they tend to send charges around the circuit in opposite directions. The actual direction of the current in the circuit is determined by the battery with the larger emf, which happens to be battery B, so the chemical energy within battery B is decreasing as energy is transferred to the charge carriers passing through it. However, the chemical energy within battery A is increasing because the current in it is directed from the positive terminal to the negative terminal. Thus, battery B is charging battery A. Battery B is also providing energy to motor M and energy that is being dissipated by resistance $R$. Figure 27-2b shows all three energy transfers from battery B; each decreases that battery's chemical energy.

Calculating the Current in a Single-Loop Circuit

We discuss here two equivalent ways to calculate the current in the simple single-loop circuit of Fig. 27-3; one method is based on energy conservation considerations, and the other on the concept of potential. The circuit consists of an ideal battery B with emf $\mathcal{E}$, a resistor of resistance $R$, and two connecting wires. (Unless otherwise indicated, we assume that wires in circuits have negligible resistance. Their function, then, is merely to provide pathways along which charge carriers can move.)

**Energy Method**

Equation 26-27 ($P = i^2R$) tells us that in a time interval $dt$ an amount of energy given by $i^2R \, dt$ will appear in the resistor of Fig. 27-3 as thermal energy. As noted in Module 26-5, this energy is said to be dissipated. (Because we assume the wires to have negligible resistance, no thermal energy will appear in them.) During the same interval, a charge $dq = idt$ will have moved through battery B, and the work that the battery will have done on this charge, according to Eq. 27-1, is

$$dW = \mathcal{E} \, dq = \mathcal{E} \, idt.$$

From the principle of conservation of energy, the work done by the (ideal) battery must equal the thermal energy that appears in the resistor:

$$\mathcal{E} \, idt = i^2R \, dt.$$

This gives us

$$\mathcal{E} = iR.$$

The emf $\mathcal{E}$ is the energy per unit charge transferred to the moving charges by the battery. The quantity $iR$ is the energy per unit charge transferred from the moving charges to thermal energy within the resistor. Therefore, this equation means that the energy per unit charge transferred to the moving charges is equal to the energy per unit charge transferred from them. Solving for $i$, we find

$$i = \frac{\mathcal{E}}{R}. \quad (27-2)$$

**Potential Method**

Suppose we start at any point in the circuit of Fig. 27-3 and mentally proceed around the circuit in either direction, adding algebraically the potential differences that we encounter. Then when we return to our starting point, we must also have returned to our starting potential. Before actually doing so, we shall formalize this idea in a statement that holds not only for single-loop circuits such as that of Fig. 27-3 but also for any complete loop in a multiloop circuit, as we shall discuss in Module 27-2:
This is often referred to as Kirchhoff’s loop rule (or Kirchhoff’s voltage law), after German physicist Gustav Robert Kirchhoff. This rule is equivalent to saying that each point on a mountain has only one elevation above sea level. If you start from any point and return to it after walking around the mountain, the algebraic sum of the changes in elevation that you encounter must be zero.

In Fig. 27-3, let us start at point $a$, whose potential is $V_a$, and mentally walk clockwise around the circuit until we are back at $a$, keeping track of potential changes as we move. Our starting point is at the low-potential terminal of the battery. Because the battery is ideal, the potential difference between its terminals is equal to $\mathcal{E}$. When we pass through the battery to the high-potential terminal, the change in potential is $\mathcal{E}/R$. As we walk along the top wire to the top end of the resistor, there is no potential change because the wire has negligible resistance; it is at the same potential as the high-potential terminal of the battery. So too is the top end of the resistor. When we pass through the resistor, however, the potential changes according to Eq. 26-8 (which we can rewrite as $V = iR$). Moreover, the potential must decrease because we are moving from the higher potential side of the resistor. Thus, the change in potential is $-\mathcal{E}/R$.

We return to point $a$ by moving along the bottom wire. Because this wire also has negligible resistance, we again find no potential change. Back at point $a$, the potential is again $V_a$. Because we traversed a complete loop, our initial potential, as modified for potential changes along the way, must be equal to our final potential; that is,

$$V_a + \mathcal{E} - iR = V_a.$$  

The value of $V_a$ cancels from this equation, which becomes

$$\mathcal{E} - iR = 0.$$  

Solving this equation for $i$ gives us the same result, $i = \mathcal{E}/R$, as the energy method (Eq. 27-2).

If we apply the loop rule to a complete counterclockwise walk around the circuit, the rule gives us

$$-\mathcal{E} + iR = 0$$  

and we again find that $i = \mathcal{E}/R$. Thus, you may mentally circle a loop in either direction to apply the loop rule.

To prepare for circuits more complex than that of Fig. 27-3, let us set down two rules for finding potential differences as we move around a loop:

**Resistance Rule:** For a move through a resistance in the direction of the current, the change in potential is $-iR$; in the opposite direction it is $+iR$.

**Emf Rule:** For a move through an ideal emf device in the direction of the emf arrow, the change in potential is $+\mathcal{E}$; in the opposite direction it is $-\mathcal{E}$.

**Checkpoint 1**

The figure shows the current $i$ in a single-loop circuit with a battery $B$ and a resistance $R$ (and wires of negligible resistance). (a) Should the emf arrow at $B$ be drawn pointing leftward or rightward? At points $a$, $b$, and $c$, rank (b) the magnitude of the current, (c) the electric potential, and (d) the electric potential energy of the charge carriers, greatest first.
**Other Single-Loop Circuits**

Next we extend the simple circuit of Fig. 27-3 in two ways.

**Internal Resistance**

Figure 27-4a shows a real battery, with internal resistance \( r \), wired to an external resistor of resistance \( R \). The internal resistance of the battery is the electrical resistance of the conducting materials of the battery and thus is an unremovable feature of the battery. In Fig. 27-4a, however, the battery is drawn as if it could be separated into an ideal battery with emf \( \mathcal{E} \) and a resistor of resistance \( r \). The order in which the symbols for these separated parts are drawn does not matter.

If we apply the loop rule clockwise beginning at point \( a \), the changes in potential give us

\[
\frac{\mathcal{E}}{iR} - iR = 0.
\]

(27-3)

Solving for the current, we find

\[
i = \frac{\mathcal{E}}{R + r}.
\]

(27-4)

Note that this equation reduces to Eq. 27-2 if the battery is ideal—that is, if \( r = 0 \).

Figure 27-4b shows graphically the changes in electric potential around the circuit. (To better link Fig. 27-4b with the closed circuit in Fig. 27-4a, imagine curling the graph into a cylinder with point \( a \) at the left overlapping point \( a \) at the right.) Note how traversing the circuit is like walking around a (potential) mountain back to your starting point—you return to the starting elevation.

In this book, when a battery is not described as real or if no internal resistance is indicated, you can generally assume that it is ideal—but, of course, in the real world batteries are always real and have internal resistance.

**Resistances in Series**

Figure 27-5a shows three resistances connected in series to an ideal battery with emf \( \mathcal{E} \). This description has little to do with how the resistances are drawn. Rather, “in series” means that the resistances are wired one after another and that a potential difference \( V \) is applied across the two ends of the series. In Fig. 27-5a, the resistances are connected one after another between \( a \) and \( b \), and a potential difference is maintained across \( a \) and \( b \) by the battery. The potential differences that then exist across the resistances in the series produce identical currents \( i \) in them. In general,
When a potential difference \( V \) is applied across resistances connected in series, the resistances have identical currents \( i \). The sum of the potential differences across the resistances is equal to the applied potential difference \( V \).

Note that charge moving through the series resistances can move along only a single route. If there are additional routes, so that the currents in different resistances are different, the resistances are not connected in series.

Resistances connected in series can be replaced with an equivalent resistance \( R_{eq} \) that has the same current \( i \) and the same total potential difference \( V \) as the actual resistances.

You might remember that \( R_{eq} \) and all the actual series resistances have the same current \( i \) with the nonsense word “ser-i.” Figure 27-5b shows the equivalent resistance \( R_{eq} \) that can replace the three resistances of Fig. 27-5a.

To derive an expression for \( R_{eq} \) in Fig. 27-5b, we apply the loop rule to both circuits. For Fig. 27-5a, starting at \( a \) and going clockwise around the circuit, we find

\[
\varepsilon - iR_1 - iR_2 - iR_3 = 0,
\]

or

\[
\frac{\varepsilon}{i} = R_1 + R_2 + R_3. \tag{27-5}
\]

For Fig. 27-5b, with the three resistances replaced with a single equivalent resistance \( R_{eq} \), we find

\[
\varepsilon - iR_{eq} = 0,
\]

or

\[
\frac{\varepsilon}{i} = \frac{1}{R_{eq}}. \tag{27-6}
\]

Comparison of Eqs. 27-5 and 27-6 shows that

\[
R_{eq} = R_1 + R_2 + R_3.
\]

The extension to \( n \) resistances is straightforward and is

\[
R_{eq} = \sum_{j=1}^{n} R_j \quad (n \text{ resistances in series}). \tag{27-7}
\]

Note that when resistances are in series, their equivalent resistance is greater than any of the individual resistances.

**Checkpoint 2**

In Fig. 27-5a, if \( R_1 > R_2 > R_3 \), rank the three resistances according to (a) the current through them and (b) the potential difference across them, greatest first.

**Potential Difference Between Two Points**

We often want to find the potential difference between two points in a circuit. For example, in Fig. 27-6, what is the potential difference \( V_b - V_a \) between points \( a \) and \( b \)? To find out, let’s start at point \( a \) (at potential \( V_a \) ) and move through the battery to point \( b \) (at potential \( V_b \) ) while keeping track of the potential changes we encounter. When we pass through the battery’s emf, the potential increases by \( \varepsilon \). When we pass through the battery’s internal resistance \( r \), we move in the direction of the current and thus the potential decreases by \( ir \). We are then at the terminals of a real battery, differ in potential.

The internal resistance reduces the potential difference between the terminals.

**Figure 27-6** Points \( a \) and \( b \), which are at the terminals.
potential of point \( b \) and we have
\[
V_a + \varepsilon - ir = V_b,
\]
or
\[
V_b - V_a = \varepsilon - ir. \tag{27-8}
\]
To evaluate this expression, we need the current \( i \). Note that the circuit is the same as in Fig. 27-4a, for which Eq. 27-4 gives the current as
\[
i = \frac{\varepsilon}{R + r}. \tag{27-9}
\]
Substituting this equation into Eq. 27-8 gives us
\[
V_b - V_a = \varepsilon - \frac{\varepsilon}{R + r} r
\]
\[
= \frac{\varepsilon}{R + r} R. \tag{27-10}
\]
Now substituting the data given in Fig. 27-6, we have
\[
V_b - V_a = \frac{12 \text{ V}}{4.0 \Omega + 2.0 \Omega} 4.0 \Omega = 8.0 \text{ V}. \tag{27-11}
\]
Suppose, instead, we move from \( a \) to \( b \) counterclockwise, passing through resistor \( R \) rather than through the battery. Because we move opposite the current, the potential increases by \( iR \). Thus,
\[
V_a + iR = V_b
\]
or
\[
V_b - V_a = iR. \tag{27-12}
\]
Substituting for \( i \) from Eq. 27-9, we again find Eq. 27-10. Hence, substitution of the data in Fig. 27-6 yields the same result, \( V_b - V_a = 8.0 \text{ V} \). In general,

To find the potential between any two points in a circuit, start at one point and traverse the circuit to the other point, following any path, and add algebraically the changes in potential you encounter.

### Potential Difference Across a Real Battery

In Fig. 27-6, points \( a \) and \( b \) are located at the terminals of the battery. Thus, the potential difference \( V_b - V_a \) is the terminal-to-terminal potential difference \( V \) across the battery. From Eq. 27-8, we see that
\[
V = \varepsilon - ir. \tag{27-13}
\]
If the internal resistance \( r \) of the battery in Fig. 27-6 were zero, Eq. 27-13 tells us that \( V \) would be equal to the emf \( \varepsilon \) of the battery—namely, 12 V. However, because \( r = 2.0 \Omega \), Eq. 27-13 tells us that \( V \) is less than \( \varepsilon \). From Eq. 27-11, we know that \( V \) is only 8.0 V. Note that the result depends on the value of the current through the battery. If the same battery were in a different circuit and had a different current through it, \( V \) would have some other value.

### Grounding a Circuit

Figure 27-7a shows the same circuit as Fig. 27-6 except that here point \( a \) is directly connected to ground, as indicated by the common symbol . \( \bigstar \). **Grounding a circuit** usually means connecting the circuit to a conducting path to Earth’s surface (actually to the electrically conducting moist dirt and rock below ground). Here, such a connection means only that the potential is defined to be zero at the grounding point in the circuit. Thus in Fig. 27-7a, the potential at \( a \) is defined to be \( V_a = 0 \). Equation 27-11 then tells us that the potential at \( b \) is \( V_b = 8.0 \text{ V} \).
Figure 27-7 (a) Point a is directly connected to ground. (b) Point b is directly connected to ground.

Figure 27-7b is the same circuit except that point b is now directly connected to ground. Thus, the potential there is defined to be $V_b = 0$. Equation 27-11 now tells us that the potential at a is $V_a = -8.0 \, \text{V}$.

**Power, Potential, and Emf**

When a battery or some other type of emf device does work on the charge carriers to establish a current $i$, the device transfers energy from its source of energy (such as the chemical source in a battery) to the charge carriers. Because a real emf device has an internal resistance $r$, it also transfers energy to internal thermal energy via resistive dissipation (Module 26-5). Let us relate these transfers.

The net rate $P$ of energy transfer from the emf device to the charge carriers is given by Eq. 26-26:

$$P = iV,$$

where $V$ is the potential across the terminals of the emf device. From Eq. 27-13, we can substitute $V = \varepsilon - ir$ into Eq. 27-14 to find

$$P = i(\varepsilon - ir) = i\varepsilon - ir.$$  \hspace{1cm} (27-15)

From Eq. 26-27, we recognize the term $i^2r$ in Eq. 27-15 as the rate $P_r$ of energy transfer to thermal energy within the emf device:

$$P_r = i^2r$$ \hspace{1cm} (internal dissipation rate).  \hspace{1cm} (27-16)

Then the term $i\varepsilon$ in Eq. 27-15 must be the rate $P_{\text{emf}}$ at which the emf device transfers energy both to the charge carriers and to internal thermal energy. Thus,

$$P_{\text{emf}} = i\varepsilon$$ \hspace{1cm} (power of emf device).  \hspace{1cm} (27-17)

If a battery is being recharged, with a “wrong way” current through it, the energy transfer is then from the charge carriers to the battery—both to the battery’s chemical energy and to the energy dissipated in the internal resistance $r$. The rate of change of the chemical energy is given by Eq. 27-17, the rate of dissipation is given by Eq. 27-16, and the rate at which the carriers supply energy is given by Eq. 27-14.

**Checkpoint 3**

A battery has an emf of 12 V and an internal resistance of 2 Ω. Is the terminal-to-terminal potential difference greater than, less than, or equal to 12 V if the current in the battery is (a) from the negative to the positive terminal, (b) from the positive to the negative terminal, and (c) zero?
Sample Problem 27.01 Single-loop circuit with two real batteries

The emfs and resistances in the circuit of Fig. 27-8a have the following values:
\[ \mathcal{E}_1 = 4.4 \text{ V}, \quad \mathcal{E}_2 = 2.1 \text{ V}, \]
\[ r_1 = 2.3 \Omega, \quad r_2 = 1.8 \Omega, \quad R = 5.5 \Omega. \]

(a) What is the current \( i \) in the circuit?

**KEY IDEA**

We can get an expression involving the current \( i \) in this single-loop circuit by applying the loop rule, in which we sum the potential changes around the full loop.

**Calculations:** Although knowing the direction of \( i \) is not necessary, we can easily determine it from the emfs of the two batteries. Because \( \mathcal{E}_1 \) is greater than \( \mathcal{E}_2 \), battery 1 controls the direction of \( i \), so the direction is clockwise. Let us then apply the loop rule by going counterclockwise—against the current—and starting at point \( a \). (These decisions about where to start and which way you go are arbitrary but, once made, you must be consistent with decisions about the plus and minus signs.) We find
\[ -\mathcal{E}_1 + ir_1 + iR + ir_2 + \mathcal{E}_2 = 0. \]

Check that this equation also results if we apply the loop rule clockwise or start at some point other than \( a \). Also, take the time to compare this equation term by term with Fig. 27-8b, which shows the potential changes graphically (with the potential at point \( a \) arbitrarily taken to be zero).

Solving the above loop equation for the current \( i \), we obtain
\[ i = \frac{\mathcal{E}_1 - \mathcal{E}_2}{R + r_1 + r_2} = \frac{4.4 \text{ V} - 2.1 \text{ V}}{5.5 \Omega + 2.3 \Omega + 1.8 \Omega} \]
\[ = 0.2396 \text{ A} = 240 \text{ mA}. \quad \text{(Answer)} \]

(b) What is the potential difference between the terminals of battery 1 in Fig. 27-8a?

**KEY IDEA**

We need to sum the potential differences between points \( a \) and \( b \).

**Calculations:** Let us start at point \( b \) (effectively the negative terminal of battery 1) and travel clockwise through battery 1 to point \( a \) (effectively the positive terminal), keeping track of potential changes. We find that
\[ V_a - ir_1 + \mathcal{E}_1 = V_a, \]
which gives us
\[ V_a - V_b = -ir_1 + \mathcal{E}_1 \]
\[ = -(0.2396 \text{ A})(2.3 \Omega) + 4.4 \text{ V} \]
\[ = +3.84 \text{ V} \approx 3.8 \text{ V}, \quad \text{(Answer)} \]
which is less than the emf of the battery. You can verify this result by starting at point \( b \) in Fig. 27-8a and traversing the circuit counterclockwise to point \( a \). We learn two points here. (1) The potential difference between two points in a circuit is independent of the path we choose to go from one to the other. (2) When the current in the battery is in the “proper” direction, the terminal-to-terminal potential difference is low, that is, lower than the stated emf for the battery that you might find printed on the battery.
27-2 MULTILoop CIRCUITS

Learning Objectives

After reading this module, you should be able to . . .

27.17 Apply the junction rule.
27.18 Draw a schematic diagram for a battery and three parallel resistors and distinguish it from a diagram with a battery and three series resistors.
27.19 Identify that resistors in parallel have the same potential difference, which is the same value that their equivalent resistor has.
27.20 Calculate the resistance of the equivalent resistor of several resistors in parallel.
27.21 Identify that the total current through parallel resistors is the sum of the currents through the individual resistors.
27.22 For a circuit with a battery and some resistors in parallel and some in series, simplify the circuit in steps by finding equivalent resistors, until the current through the battery can be determined, and then reverse the steps to find the currents and potential differences of the individual resistors.
27.23 If a circuit cannot be simplified by using equivalent resistors, identify the several loops in the circuit, choose names and directions for the currents in the branches, set up loop equations for the various loops, and solve these simultaneous equations for the unknown currents.
27.24 In a circuit with identical real batteries in series, replace them with a single ideal battery and a single resistor.
27.25 In a circuit with identical real batteries in parallel, replace them with a single ideal battery and a single resistor.

Key Idea

When resistances are in parallel, they have the same potential difference. The equivalent resistance that can replace a parallel combination of resistances is given by

\[
\frac{1}{R_{eq}} = \sum_{j=1}^{n} \frac{1}{R_j} \quad (n \text{ resistances in parallel}).
\]

Multiloop Circuits

Figure 27-9 shows a circuit containing more than one loop. For simplicity, we assume the batteries are ideal. There are two junctions in this circuit, at b and d, and there are three branches connecting these junctions. The branches are the left branch (bad), the right branch (bcd), and the central branch (bd). What are the currents in the three branches?

We arbitrarily label the currents, using a different subscript for each branch. Current \(i_1\) has the same value everywhere in branch bad, \(i_2\) has the same value everywhere in branch bcd, and \(i_3\) is the current through branch bd. The directions of the currents are assumed arbitrarily.

Consider junction d for a moment: Charge comes into that junction via incoming currents \(i_1\) and \(i_3\), and it leaves via outgoing current \(i_2\). Because there is no variation in the charge at the junction, the total incoming current must equal the total outgoing current:

\[
i_1 + i_3 = i_2. \tag{27-18}\]

You can easily check that applying this condition to junction b leads to exactly the same equation. Equation 27-18 thus suggests a general principle:

**JUNCTION RULE:** The sum of the currents entering any junction must be equal to the sum of the currents leaving that junction.

This rule is often called Kirchhoff’s junction rule (or Kirchhoff’s current law). It is simply a statement of the conservation of charge for a steady flow of charge—there is neither a buildup nor a depletion of charge at a junction. Thus, our basic tools for solving complex circuits are the loop rule (based on the conservation of energy) and the junction rule (based on the conservation of charge).

Figure 27-9 A multiloop circuit consisting of three branches: left-hand branch bad, right-hand branch bcd, and central branch bd. The circuit also consists of three loops: left-hand loop badb, right-hand loop bcd, and big loop badcb.
Equation 27-18 is a single equation involving three unknowns. To solve the circuit completely (that is, to find all three currents), we need two more equations involving those same unknowns. We obtain them by applying the loop rule twice. In the circuit of Fig. 27-9, we have three loops from which to choose: the left-hand loop (badb), the right-hand loop (bcdb), and the big loop (badcb). Which two loops we choose does not matter—let’s choose the left-hand loop and the right-hand loop.

If we traverse the left-hand loop in a counterclockwise direction from point b, the loop rule gives us

$$\mathcal{E}_1 - i_1R_1 + i_3R_3 = 0. \quad (27-19)$$

If we traverse the right-hand loop in a counterclockwise direction from point b, the loop rule gives us

$$-i_3R_3 - i_2R_2 - \mathcal{E}_2 = 0. \quad (27-20)$$

We now have three equations (Eqs. 27-18, 27-19, and 27-20) in the three unknown currents, and they can be solved by a variety of techniques.

If we had applied the loop rule to the big loop, we would have obtained (moving counterclockwise from b) the equation

$$\mathcal{E}_1 - i_1R_1 - i_2R_2 - \mathcal{E}_2 = 0.$$

However, this is merely the sum of Eqs. 27-19 and 27-20.

**Resistances in Parallel**

Figure 27-10a shows three resistances connected in parallel to an ideal battery of emf $\mathcal{E}$. The term “in parallel” means that the resistances are directly wired together on one side and directly wired together on the other side, and that a potential difference $V$ is applied across the pair of connected sides. Thus, all three resistances have the same potential difference $V$ across them, producing a current through each. In general,

When a potential difference $V$ is applied across resistances connected in parallel, the resistances all have that same potential difference $V$.

In Fig. 27-10a, the applied potential difference $V$ is maintained by the battery. In Fig. 27-10b, the three parallel resistances have been replaced with an equivalent resistance $R_{eq}$. 

---

[Diagram showing parallel resistors and their equivalent]
Resistances connected in parallel can be replaced with an equivalent resistance \( R_{eq} \) that has the same potential difference \( V \) and the same total current \( i \) as the actual resistances.

You might remember that \( R_{eq} \) and all the actual parallel resistances have the same potential difference \( V \) with the nonsense word “par-V.”

To derive an expression for \( R_{eq} \) in Fig. 27-10, we first write the current in each actual resistance in Fig. 27-10 as

\[
i_1 = \frac{V}{R_1}, \quad i_2 = \frac{V}{R_2}, \quad \text{and} \quad i_3 = \frac{V}{R_3},
\]

where \( V \) is the potential difference between \( a \) and \( b \). If we apply the junction rule at point \( a \) in Fig. 27-10a and then substitute these values, we find

\[
i = i_1 + i_2 + i_3 = V \left( \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} \right).
\]  

(27-21)

If we replaced the parallel combination with the equivalent resistance \( R_{eq} \) (Fig. 27-10b), we would have

\[
i = \frac{V}{R_{eq}}.
\]  

(27-22)

Comparing Eqs. 27-21 and 27-22 leads to

\[
\frac{1}{R_{eq}} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}.
\]

(27-23)

Extending this result to the case of \( n \) resistances, we have

\[
\frac{1}{R_{eq}} = \sum_{j=1}^{n} \frac{1}{R_j} \quad (n \text{ resistances in parallel}).
\]  

(27-24)

For the case of two resistances, the equivalent resistance is their product divided by their sum; that is,

\[
R_{eq} = \frac{R_1R_2}{R_1 + R_2}.
\]  

(27-25)

Note that when two or more resistances are connected in parallel, the equivalent resistance is smaller than any of the combining resistances. Table 27-1 summarizes the equivalence relations for resistors and capacitors in series and in parallel.

**Checkpoint 4**

A battery, with potential \( V \) across it, is connected to a combination of two identical resistors and then has current \( i \) through it. What are the potential difference across and the current through either resistor if the resistors are (a) in series and (b) in parallel?
Sample Problem 27.02  Resistors in parallel and in series

Figure 27-11a shows a multiloop circuit containing one ideal battery and four resistances with the following values:

\[ R_1 = 20 \, \Omega, \quad R_2 = 20 \, \Omega, \quad \varepsilon = 12 \, V, \]
\[ R_3 = 30 \, \Omega, \quad R_4 = 8.0 \, \Omega. \]

(a) What is the current through the battery?

**KEY IDEA**

Noting that the current through the battery must also be the current through \( R_1 \), we see that we might find the current by applying the loop rule to a loop that includes \( R_1 \) because the current would be included in the potential difference across \( R_1 \).

**Incorrect method:** Either the left-hand loop or the big loop should do. Noting that the emf arrow of the battery points upward, so the current the battery supplies is clockwise, we might apply the loop rule to the left-hand loop, clockwise from point \( a \). With \( i \) being the current through the battery, we would get

\[ +\varepsilon - iR_1 - iR_2 - iR_4 = 0 \quad \text{(incorrect)}. \]

However, this equation is incorrect because it assumes that \( R_1, R_2, \) and \( R_4 \) all have the same current \( i \). Resistances \( R_1 \) and \( R_4 \) do have the same current, because the current passing through \( R_4 \) must pass through the battery and then through \( R_1 \) with no change in value. However, that current splits at junction point \( b \)—only part passes through \( R_2 \), the rest through \( R_3 \).

**Dead-end method:** To distinguish the several currents in the circuit, we must label them individually as in Fig. 27-11b. Then, circling clockwise from \( a \), we can write the loop rule for the left-hand loop as

\[ +\varepsilon - i_1R_1 - i_2R_2 - i_4R_4 = 0. \]

Unfortunately, this equation contains two unknowns, \( i_1 \) and \( i_4 \); we would need at least one more equation to find them.

**Successful method:** A much easier option is to simplify the circuit of Fig. 27-11b by finding equivalent resistances. Note carefully that \( R_1 \) and \( R_2 \) are not in series and thus cannot be replaced with an equivalent resistance. However, \( R_2 \) and \( R_3 \) are in parallel, so we can use either Eq. 27-24 or Eq. 27-25 to find their equivalent resistance \( R_{23} \). From the latter,

\[ R_{23} = \frac{R_2R_3}{R_2 + R_3} = \frac{(20 \, \Omega)(30 \, \Omega)}{50 \, \Omega} = 12 \, \Omega. \]

We can now redraw the circuit as in Fig. 27-11c; note that the current through \( R_{23} \) must be \( i_1 \) because charge that moves through \( R_1 \) and \( R_4 \) must also move through \( R_{23} \). For this simple one-loop circuit, the loop rule (applied clockwise from point \( a \) as in Fig. 27-11d) yields

\[ +\varepsilon - i_1R_1 - i_2R_{23} - i_4R_4 = 0. \]

Substituting the given data, we find

\[ 12 \, V - i_1(20 \, \Omega) - i_2(12 \, \Omega) - i_4(8.0 \, \Omega) = 0, \]

which gives us

\[ i_1 = \frac{12 \, V}{40 \, \Omega} = 0.30 \, A. \quad \text{(Answer)} \]

(b) What is the current \( i_2 \) through \( R_2 \)?

**KEY IDEAS**

(1) we must now work backward from the equivalent circuit of Fig. 27-11d, where \( R_{23} \) has replaced \( R_2 \) and \( R_3 \). (2) Because \( R_1 \) and \( R_4 \) are in parallel, they both have the same potential difference across them as \( R_{23} \).

**Working backward:** We know that the current through \( R_{23} \) is \( i_1 = 0.30 \, A \). Thus, we can use Eq. 26-8 \((R = V/i)\) and Fig. 27-11e to find the potential difference \( V_{23} \) across \( R_{23} \). Setting \( R_{23} = 12 \, \Omega \) from (a), we write Eq. 26-8 as

\[ V_{23} = i_1R_{23} = (0.30 \, A)(12 \, \Omega) = 3.6 \, V. \]

The potential difference across \( R_2 \) is thus also 3.6 V (Fig. 27-11f), so the current \( i_2 \) in \( R_2 \) must be, by Eq. 26-8 and Fig. 27-11g,

\[ i_2 = \frac{V_{23}}{R_2} = \frac{3.6 \, V}{20 \, \Omega} = 0.18 \, A. \quad \text{(Answer)} \]

(c) What is the current \( i_3 \) through \( R_3 \)?

**KEY IDEAS**

We can answer by using either of two techniques: (1) Apply Eq. 26-8 as we just did. (2) Use the junction rule, which tells us that at point \( b \) in Fig. 27-11b, the incoming current \( i_1 \) and the outgoing currents \( i_2 \) and \( i_3 \) are related by

\[ i_1 = i_2 + i_3. \]

**Calculation:** Rearranging this junction-rule result yields the result displayed in Fig. 27-11g:

\[ i_3 = i_1 - i_2 = 0.30 \, A - 0.18 \, A \\
= 0.12 \, A. \quad \text{(Answer)} \]
Figure 27-11  (a) A circuit with an ideal battery. (b) Label the currents. (c) Replacing the parallel resistors with their equivalent. 
(d)–(g) Working backward to find the currents through the parallel resistors.
Sample Problem 27.03  Many real batteries in series and in parallel in an electric fish

Electric fish can generate current with biological emf cells called electroplaques. In the South American eel they are arranged in 140 rows, each row stretching horizontally along the body and each containing 5000 cells, as suggested by Fig. 27-12a. Each electroplaque has an emf $\mathcal{E}$ of 0.15 V and an internal resistance $r$ of 0.25 $\Omega$. The water surrounding the eel completes a circuit between the two ends of the electroplaque array, one end at the head of the animal and the other near the tail.

(a) If the surrounding water has resistance $R_w = 800 \, \Omega$, how much current can the eel produce in the water?

**KEY IDEA**

We can simplify the circuit of Fig. 27-12a by replacing combinations of emfs and internal resistances with equivalent emfs and resistances.

**Calculations:** We first consider a single row. The total emf $\mathcal{E}_{row}$ along a row of 5000 electroplaques is the sum of the emfs:

$$\mathcal{E}_{row} = 5000 \mathcal{E} = (5000)(0.15 \text{ V}) = 750 \text{ V}.$$ 

The total resistance $R_{row}$ along a row is the sum of the internal resistances of the 5000 electroplaques:

$$R_{row} = 5000r = (5000)(0.25 \, \Omega) = 1250 \, \Omega.$$ 

We can now represent each of the 140 identical rows as having a single emf $\mathcal{E}_{row}$ and a single resistance $R_{row}$ (Fig. 27-12b).

In Fig. 27-12b, the emf between point $a$ and point $b$ on any row is $\mathcal{E}_{row} = 750 \text{ V}$. Because the rows are identical and because they are all connected together at the left in Fig. 27-12b, all points $b$ in that figure are at the same electric potential. Thus, we can consider them to be connected so that there is only a single point $b$. The emf between point $a$ and this single point $b$ is $\mathcal{E}_{row} = 750 \text{ V}$, so we can draw the circuit as shown in Fig. 27-12c.

Between points $b$ and $c$ in Fig. 27-12c are 140 resistances $R_{row} = 1250 \, \Omega$, all in parallel. The equivalent resistance $R_{eq}$ of this combination is given by Eq. 27-24 as

$$\frac{1}{R_{eq}} = \sum_{j=1}^{140} \frac{1}{R_j} = 140 \frac{1}{R_{row}},$$

or

$$R_{eq} = \frac{R_{row}}{140} = \frac{1250 \, \Omega}{140} = 8.93 \, \Omega.$$ 

**Figure 27-12** (a) A model of the electric circuit of an eel in water. Along each of 140 rows extending from the head to the tail of the eel, there are 5000 electroplaques. The surrounding water has resistance $R_w$.

(b) The emf $\mathcal{E}_{row}$ and resistance $R_{row}$ of each row.

(c) The emf between points $a$ and $b$ is $\mathcal{E}_{row}$. Between points $b$ and $c$ are 140 parallel resistances $R_{row}$.

(d) The simplified circuit.
Replacing the parallel combination with \( R_{eq} \), we obtain the simplified circuit of Fig. 27-12d. Applying the loop rule to this circuit counterclockwise from point \( b \), we have

\[
\bar{E}_{row} - iR_w - iR_{eq} = 0.
\]

Solving for \( i \) and substituting the known data, we find

\[
i = \frac{\bar{E}_{row}}{R_w + R_{eq}} = \frac{750 \, \text{V}}{800 \, \Omega + 8.93 \, \Omega} = 0.927 \, \text{A} \approx 0.93 \, \text{A}.
\]

(Answer)

If the head or tail of the eel is near a fish, some of this current could pass along a narrow path through the fish, stunning or killing it.

**Sample Problem 27.04  Multiloop circuit and simultaneous loop equations**

Figure 27-13 shows a circuit whose elements have the following values: \( \bar{E}_1 = 3.0 \, \text{V}, \bar{E}_2 = 6.0 \, \text{V}, \, R_1 = 2.0 \, \Omega, \, R_2 = 4.0 \, \Omega \). The three batteries are ideal batteries. Find the magnitude and direction of the current in each of the three branches.

**KEY IDEAS**

It is not worthwhile to try to simplify this circuit, because no two resistors are in parallel, and the resistors that are in series (those in the right branch or those in the left branch) present no problem. So, our plan is to apply the junction and loop rules.

**Junction rule:** Using arbitrarily chosen directions for the currents as shown in Fig. 27-13, we apply the junction rule at point \( a \) by writing

\[
i_3 = i_1 + i_2.
\]

(27-26)

An application of the junction rule at junction \( b \) gives only the same equation, so we next apply the loop rule to any two of the three loops of the circuit.

**Left-hand loop:** We first arbitrarily choose the left-hand loop, arbitrarily start at point \( b \), and arbitrarily traverse the loop in the clockwise direction, obtaining

\[
-i_1R_1 + \bar{E}_1 - i_1R_1 - (i_1 + i_2)R_2 - \bar{E}_2 = 0,
\]

where we have used \((i_1 + i_2)\) instead of \(i_3\) in the middle branch. Substituting the given data and simplifying yield

\[
i_1(8.0 \, \Omega) + i_2(4.0 \, \Omega) = -3.0 \, \text{V}.
\]

(27-27)

**Right-hand loop:** For our second application of the loop rule, we arbitrarily choose to traverse the right-hand loop counterclockwise from point \( b \), finding

\[
-i_2R_1 + \bar{E}_2 - i_2R_1 - (i_1 + i_2)R_2 - \bar{E}_2 = 0.
\]

Substituting the given data and simplifying yield

\[
i_1(4.0 \, \Omega) + i_2(8.0 \, \Omega) = 0.
\]

(27-28)

(b) How much current \( i_{row} \) travels through each row of Fig. 27-12a?

**KEY IDEA**

Because the rows are identical, the current into and out of the eel is evenly divided among them.

**Calculation:** Thus, we write

\[
i_{row} = \frac{i}{140} = \frac{0.927 \, \text{A}}{140} = 6.6 \times 10^{-3} \, \text{A}.
\]

(Answer)

Thus, the current through each row is small, so that the eel need not stun or kill itself when it stuns or kills a fish.

---

**Additional examples, video, and practice available at WileyPLUS**
27-3 THE AMMETER AND THE VOLTMETER

Learning Objective

After reading this module, you should be able to . . .

27.26 Explain the use of an ammeter and a voltmeter, including the resistance required of each in order not to affect the measured quantities.

Key Idea

● Here are three measurement instruments used with circuits: An ammeter measures current. A voltmeter measures voltage (potential differences). A multimeter can be used to measure current, voltage, or resistance.

The Ammeter and the Voltmeter

An instrument used to measure currents is called an ammeter. To measure the current in a wire, you usually have to break or cut the wire and insert the ammeter so that the current to be measured passes through the meter. (In Fig. 27-14, ammeter A is set up to measure current \(i\).) It is essential that the resistance \(R_A\) of the ammeter be very much smaller than other resistances in the circuit. Otherwise, the very presence of the meter will change the current to be measured.

A meter used to measure potential differences is called a voltmeter. To find the potential difference between any two points in the circuit, the voltmeter terminals are connected between those points without breaking or cutting the wire. (In Fig. 27-14, voltmeter V is set up to measure the voltage across \(R_1\).) It is essential that the resistance \(R_V\) of a voltmeter be very much larger than the resistance of any circuit element across which the voltmeter is connected. Otherwise, the meter alters the potential difference that is to be measured.

Often a single meter is packaged so that, by means of a switch, it can be made to serve as either an ammeter or a voltmeter — and usually also as an ohmmeter, designed to measure the resistance of any element connected between its terminals. Such a versatile unit is called a multimeter.

27-4 RC CIRCUITS

Learning Objectives

After reading this module, you should be able to . . .

27.27 Draw schematic diagrams of charging and discharging RC circuits.
27.28 Write the loop equation (a differential equation) for a charging RC circuit.
27.29 Write the loop equation (a differential equation) for a discharging RC circuit.
27.30 For a capacitor in a charging or discharging RC circuit, apply the relationship giving the charge as a function of time.
27.31 From the function giving the charge as a function of time in a charging or discharging RC circuit, find the capacitor’s potential difference as a function of time.
27.32 In a charging or discharging RC circuit, find the resistor’s current and potential difference as functions of time.
27.33 Calculate the capacitive time constant \(\tau\).
27.34 For a charging RC circuit and a discharging RC circuit, determine the capacitor’s charge and potential difference at the start of the process and then a long time later.

Key Ideas

● When an emf \(\mathcal{E}\) is applied to a resistance \(R\) and capacitance \(C\) in series, the charge on the capacitor increases according to

\[ q = C\mathcal{E}(1 - e^{-t/RC}) \]

in which \(C\mathcal{E} = q_0\) is the equilibrium (final) charge and \(RC = \tau\) is the capacitive time constant of the circuit.

● During the charging, the current is

\[ i = \frac{dq}{dt} = \left(\frac{\mathcal{E}}{R}\right)e^{-t/RC} \]

(charging a capacitor).

● When a capacitor discharges through a resistance \(R\), the charge on the capacitor decays according to

\[ q = q_0e^{-t/RC} \]

(discharging a capacitor).

● During the discharging, the current is

\[ i = \frac{dq}{dt} = -\left(\frac{q_0}{RC}\right)e^{-t/RC} \]

(discharging a capacitor).

**RC Circuits**

In preceding modules we dealt only with circuits in which the currents did not vary with time. Here we begin a discussion of time-varying currents.

**Charging a Capacitor**

The capacitor of capacitance \( C \) in Fig. 27-15 is initially uncharged. To charge it, we close switch \( S \) on point \( a \). This completes an RC series circuit consisting of the capacitor, an ideal battery of emf \( \mathcal{E} \), and a resistance \( R \).

From Module 25-1, we already know that as soon as the circuit is complete, charge begins to flow (current exists) between a capacitor plate and a battery terminal on each side of the capacitor. This current increases the charge \( q \) on the plates and the potential difference \( V_C = q/C \) across the capacitor. When that potential difference equals the potential difference across the battery (which here is equal to the emf \( \mathcal{E} \)), the current is zero. From Eq. 25-1 \( q = CV \), the equilibrium (final) charge on the then fully charged capacitor is equal to \( C \mathcal{E} \).

Here we want to examine the charging process. In particular we want to know how the charge \( q(t) \) on the capacitor plates, the potential difference \( V_C(t) \) across the capacitor, and the current \( i(t) \) in the circuit vary with time during the charging process. We begin by applying the loop rule to the circuit, traversing it clockwise from the negative terminal of the battery. We find

\[
\mathcal{E} - iR - \frac{q}{C} = 0. \tag{27-30}
\]

The last term on the left side represents the potential difference across the capacitor. The term is negative because the capacitor’s top plate, which is connected to the battery’s positive terminal, is at a higher potential than the lower plate. Thus, there is a drop in potential as we move down through the capacitor.

We cannot immediately solve Eq. 27-30 because it contains two variables, \( i \) and \( q \). However, those variables are not independent but are related by

\[
i = \frac{dq}{dt}. \tag{27-31}
\]

Substituting this for \( i \) in Eq. 27-30 and rearranging, we find

\[
R \frac{dq}{dt} + \frac{q}{C} = \mathcal{E} \quad \text{(charging equation)}. \tag{27-32}
\]

This differential equation describes the time variation of the charge \( q \) on the capacitor in Fig. 27-15. To solve it, we need to find the function \( q(t) \) that satisfies this equation and also satisfies the condition that the capacitor be initially uncharged; that is, \( q = 0 \) at \( t = 0 \).

We shall soon show that the solution to Eq. 27-32 is

\[
q = C \mathcal{E} (1 - e^{-t/RC}) \quad \text{(charging a capacitor)}. \tag{27-33}
\]

(Here \( e \) is the exponential base, 2.718 \ldots, and not the elementary charge.) Note that Eq. 27-33 does indeed satisfy our required initial condition, because at \( t = 0 \) the term \( e^{-t/RC} \) is unity; so the equation gives \( q = 0 \). Note also that as \( t \) goes to infinity (that is, a long time later), the term \( e^{-t/RC} \) goes to zero; so the equation gives the proper value for the full (equilibrium) charge on the capacitor—namely, \( q = C \mathcal{E} \). A plot of \( q(t) \) for the charging process is given in Fig. 27-16a.

The derivative of \( q(t) \) is the current \( i(t) \) charging the capacitor:

\[
i = \frac{dq}{dt} = \frac{\mathcal{E}}{R} e^{-t/RC} \quad \text{(charging a capacitor)}. \tag{27-34}
\]
A plot of \( i(t) \) for the charging process is given in Fig. 27-16b. Note that the current has the initial value \( \epsilon/R \) and that it decreases to zero as the capacitor becomes fully charged.

By combining Eq. 25-1 \( (q = CV) \) and Eq. 27-33, we find that the potential difference \( V_C(t) \) across the capacitor during the charging process is

\[
V_C = \frac{q}{C} = \epsilon (1 - e^{-t/RC}) \quad \text{(charging a capacitor).} \quad (27-35)
\]

This tells us that \( V_C = 0 \) at \( t = 0 \) and that \( V_C = \epsilon \) when the capacitor becomes fully charged as \( t \to \infty \).

**The Time Constant**

The product \( RC \) that appears in Eqs. 27-33, 27-34, and 27-35 has the dimensions of time (both because the argument of an exponential must be dimensionless and because, in fact, \( 1.0 \text{ \Omega \times 1.0 \text{ F} = 1.0 \text{ s}} \)). The product \( RC \) is called the **capacitive time constant** of the circuit and is represented with the symbol \( \tau \):

\[
\tau = RC \quad \text{(time constant).} \quad (27-36)
\]

From Eq. 27-33, we can now see that at time \( t = \tau \ (= RC) \), the charge on the initially uncharged capacitor of Fig. 27-15 has increased from zero to

\[
q = C\epsilon (1 - e^{-1}) = 0.63C\epsilon. \quad (27-37)
\]

In words, during the first time constant \( \tau \) the charge has increased from zero to 63\% of its final value \( C\epsilon \). In Fig. 27-16, the small triangles along the time axes mark successive intervals of one time constant during the charging of the capacitor. The charging times for \( RC \) circuits are often stated in terms of \( \tau \). For example, a circuit with \( \tau = 1 \text{ \mu s} \) charges quickly while one with \( \tau = 100 \text{ s} \) charges much more slowly.

**Discharging a Capacitor**

Assume now that the capacitor of Fig. 27-15 is fully charged to a potential \( V_0 \) equal to the emf \( \epsilon \) of the battery. At a new time \( t = 0 \), switch S is thrown from \( a \) to \( b \) so that the capacitor can **discharge** through resistance \( R \). How do the charge \( q(t) \) on the capacitor and the current \( i(t) \) through the discharge loop of capacitor and resistance now vary with time?

The differential equation describing \( q(t) \) is like Eq. 27-32 except that now, with no battery in the discharge loop, \( \epsilon = 0 \). Thus,

\[
R \frac{dq}{dt} + \frac{q}{C} = 0 \quad \text{(discharging equation).} \quad (27-38)
\]

The solution to this differential equation is

\[
q = Q_0 e^{-t/RC} \quad \text{(discharging a capacitor),} \quad (27-39)
\]

where \( Q_0 \) \((= CV_0)\) is the initial charge on the capacitor. You can verify by substitution that Eq. 27-39 is indeed a solution of Eq. 27-38.
Equation 27-39 tells us that \( q \) decreases exponentially with time, at a rate that is set by the capacitive time constant \( \tau = RC \). At time \( t = \tau \), the capacitor’s charge has been reduced to \( q_0 e^{-1} \), or about 37% of the initial value. Note that a greater \( \tau \) means a greater discharge time.

Differentiating Eq. 27-39 gives us the current \( i(t) \):

\[
i = \frac{dq}{dt} = -\left( \frac{q_0}{RC} \right) e^{-t/RC} \quad \text{(discharging a capacitor).} \quad (27-40)
\]

This tells us that the current also decreases exponentially with time, at a rate set by \( \tau \). The initial current \( i_0 \) is equal to \( q_0/RC \). Note that you can find \( i_0 \) by simply applying the loop rule to the circuit at \( t = 0 \); just then the capacitor’s initial potential \( V_0 \) is connected across the resistance \( R \), so the current must be \( i_0 = V_0/R = (q_0/C)/R = q_0/RC \). The minus sign in Eq. 27-40 can be ignored; it merely means that the capacitor’s charge \( q \) is decreasing.

**Derivation of Eq. 27-33**

To solve Eq. 27-32, we first rewrite it as

\[
\frac{dq}{dt} + \frac{q}{RC} = \frac{\mathcal{E}}{R}.
\]

(27-41)

The general solution to this differential equation is of the form

\[
q = q_p + Ke^{-at},
\]

(27-42)

where \( q_p \) is a particular solution of the differential equation, \( K \) is a constant to be evaluated from the initial conditions, and \( a = 1/RC \) is the coefficient of \( q \) in Eq. 27-41. To find \( q_p \), we set \( dq/dt = 0 \) in Eq. 27-41 (corresponding to the final condition of no further charging), let \( q = q_p \), and solve, obtaining

\[
q_p = C\mathcal{E}.
\]

(27-43)

To evaluate \( K \), we first substitute this into Eq. 27-42 to get

\[
q = C\mathcal{E} + Ke^{-at}.
\]

Then substituting the initial conditions \( q = 0 \) and \( t = 0 \) yields

\[
0 = C\mathcal{E} + K,
\]

or \( K = -C\mathcal{E} \). Finally, with the values of \( q_p, a \), and \( K \) inserted, Eq. 27-42 becomes

\[
q = C\mathcal{E} - C\mathcal{E}e^{-t/RC},
\]

which, with a slight modification, is Eq. 27-33.

**Checkpoint 5**

The table gives four sets of values for the circuit elements in Fig. 27-15. Rank the sets according to (a) the initial current (as the switch is closed on \( a \)) and (b) the time required for the current to decrease to half its initial value, greatest first.

Sample Problem 27.05  Discharging an RC circuit to avoid a fire in a race car pit stop

As a car rolls along pavement, electrons move from the pavement first onto the tires and then onto the car body. The car stores this excess charge and the associated electric potential energy as if the car body were one plate of a capacitor and the pavement were the other plate (Fig. 27-17a). When the car stops, it discharges its excess charge and energy through the tires, just as a capacitor can discharge through a resistor. If a conducting object comes within a few centimeters of the car before the car is discharged, the remaining energy can be suddenly transferred to a spark between the car and the object. Suppose the conducting object is a fuel dispenser. The spark will not ignite the fuel and cause a fire if the spark energy is less than the critical value $U_{fire} = 50 \text{ mJ}$.

When the car of Fig. 27-17a stops at time $t = 0$, the car–ground potential difference is $V_0 = 30 \text{ kV}$. The car–ground capacitance is $C = 500 \text{ pF}$, and the resistance of each tire is $R_{tire} = 100 \text{ G}\Omega$. How much time does the car take to discharge through the tires to drop below the critical value $U_{fire}$?

**KEY IDEAS**

1. At any time $t$, a capacitor’s stored electric potential energy $U$ is related to its stored charge $q$ according to Eq. 25-21 ($U = q^2/2C$).
2. While a capacitor is discharging, the charge decreases with time according to Eq. 27-39 ($q = q_0 e^{-t/RC}$).

**Calculations:** We can treat the tires as resistors that are connected to one another at their tops via the car body and at their bottoms via the pavement. Figure 27-17b shows how the four resistors are connected in parallel across the car’s capacitance, and Fig. 27-17c shows their equivalent resistance $R$. From Eq. 27-24, $R$ is given by

$$\frac{1}{R} = \frac{1}{R_{tire}} + \frac{1}{R_{tire}} + \frac{1}{R_{tire}} + \frac{1}{R_{tire}},$$

or

$$R = \frac{R_{tire}}{4} = \frac{100 \times 10^9 \Omega}{4} = 25 \times 10^9 \Omega. \quad (27-44)$$

When the car stops, it discharges its excess charge and energy through $R$. We now use our two Key Ideas to analyze the discharge. Substituting Eq. 27-39 into Eq. 25-21 gives

$$U = \frac{q^2}{2C} = \frac{(q_0 e^{-t/RC})^2}{2C} = \frac{q_0^2}{2C} e^{-2t/RC}. \quad (27-45)$$

From Eq. 25-1 ($q = CV$), we can relate the initial charge $q_0$ on the car to the given initial potential difference $V_0$; $q_0 = CV_0$. Substituting this equation into Eq. 27-45 brings us to

$$U = \frac{(CV_0)^2}{2C} e^{-2t/RC} = \frac{CV_0^2}{2} e^{-2t/RC}. \quad (27-46)$$

Taking the natural logarithms of both sides, we obtain

$$-\frac{2t}{RC} = \ln \left( \frac{2U}{CV_0^2} \right). \quad (27-47)$$

Substituting the given data, we find that the time the car takes to discharge to the energy level $U_{fire} = 50 \text{ mJ}$ is

$$t = -\frac{2(25 \times 10^9 \Omega)(500 \times 10^{-12} \text{ F})}{(2(50 \times 10^{-3} \text{ J})/(500 \times 10^{-12} \text{ F})(30 \times 10^3 \text{ V})^2)} = 9.4 \text{ s}. \quad (Answer)$$

**Fire or no fire:** This car requires at least 9.4 s before fuel can be brought safely near it. A pit crew cannot wait that long. So the tires include some type of conducting material (such as carbon black) to lower the tire resistance and thus increase the discharge rate. Figure 27-17d shows the stored energy $U$ versus time $t$ for tire resistances of $R = 100 \text{ G}\Omega$ (our value) and $R = 10 \text{ G}\Omega$. Note how much more rapidly a car discharges to level $U_{fire}$ with the lower $R$ value.
**Review & Summary**

**Emf** An **emf device** does work on charges to maintain a potential difference between its output terminals. If $dW$ is the work the device does to force positive charge $dq$ from the negative to the positive terminal, then the **emf** (work per unit charge) of the device is

$$\mathcal{E} = \frac{dW}{dq} \quad \text{(definition of } \mathcal{E}). \quad (27-1)$$

The volt is the SI unit of emf as well as of potential difference. An **ideal emf device** is one that lacks any internal resistance. The potential difference between its terminals is equal to the emf. A **real emf device** has internal resistance. The potential difference between its terminals is equal to the emf only if there is no current through the device.

**Analyzing Circuits** The change in potential in traversing a resistance $R$ in the direction of the current is $-iR$; in the opposite direction it is $+iR$ (resistance rule). The change in potential in traversing an ideal emf device in the direction of the emf arrow is $+\mathcal{E}$; in the opposite direction it is $-\mathcal{E}$ (emf rule). Conservation of energy leads to the loop rule:

**Loop Rule.** The algebraic sum of the changes in potential encountered in a complete traversal of any loop of a circuit must be zero.

Conservation of charge gives us the junction rule:

**Junction Rule.** The sum of the currents entering any junction must be equal to the sum of the currents leaving that junction.

**Single-Loop Circuits** The current in a single-loop circuit containing a single resistance $R$ and an emf device with emf $\mathcal{E}$ and internal resistance $r$ is

$$i = \frac{\mathcal{E}}{R + r}, \quad (27-4)$$

which reduces to $i = \mathcal{E}/R$ for an ideal emf device with $r = 0$.

**Power** When a real battery of emf $\mathcal{E}$ and internal resistance $r$ does work on the charge carriers in a current $i$ through the battery, the rate $P$ of energy transfer to the charge carriers is

$$P = iV, \quad (27-14)$$

where $V$ is the potential across the terminals of the battery. The rate $P_r$ at which energy is dissipated as thermal energy in the battery is

$$P_r = i^2r. \quad (27-16)$$

The rate $P_{emf}$ at which the chemical energy in the battery changes is

$$P_{emf} = i\mathcal{E}. \quad (27-17)$$

**Series Resistances** When resistances are in **series**, they have the same current. The equivalent resistance that can replace a series combination of resistances is

$$R_{eq} = \sum_{i=1}^{n} R_i \quad (n \text{ resistances in series}). \quad (27-7)$$

**Parallel Resistances** When resistances are in **parallel**, they have the same potential difference. The equivalent resistance that can replace a parallel combination of resistances is given by

$$\frac{1}{R_{eq}} = \sum_{i=1}^{n} \frac{1}{R_i} \quad (n \text{ resistances in parallel}). \quad (27-24)$$

**RC Circuits** When an emf $\mathcal{E}$ is applied to a resistance $R$ and capacitance $C$ in series, as in Fig. 27-15 with the switch at $a$, the charge on the capacitor increases according to

$$q = C\mathcal{E}(1 - e^{-tRC}) \quad \text{(charging a capacitor)}, \quad (27-33)$$

in which $C\mathcal{E} = q_0$ is the equilibrium (final) charge and $RC = \tau$ is the **capacitive time constant** of the circuit. During the charging, the current is

$$i = \frac{dq}{dt} = \left(\frac{\mathcal{E}}{R}\right) e^{-tRC} \quad \text{(charging a capacitor)}. \quad (27-34)$$

When a capacitor discharges through a resistance $R$, the charge on the capacitor decays according to

$$q = q_0e^{-tRC} \quad \text{(discharging a capacitor)}. \quad (27-39)$$

During the discharging, the current is

$$i = \frac{dq}{dt} = -\left(\frac{q_0}{RC}\right) e^{-tRC} \quad \text{(discharging a capacitor)}. \quad (27-40)$$

**Questions**

1. (a) In Fig. 27-18a, with $R_1 > R_2$, is the potential difference across $R_2$ more than, less than, or equal to that across $R_1$? (b) Is the current through resistor $R_2$ more than, less than, or equal to that through resistor $R_1$?

2. (a) In Fig. 27-18a, are resistors $R_1$ and $R_3$ in series? (b) Are resistors $R_1$ and $R_2$ in parallel? (c) Rank the equivalent resistances of the four circuits shown in Fig. 27-18, greatest first.

3. You are to connect resistors $R_1$ and $R_2$, with $R_1 > R_2$, to a battery, first individually, then in series, and then in parallel. Rank those arrangements according to the amount of current through the battery, greatest first.

4. In Fig. 27-19, a circuit consists of a battery and two uniform resistors, and the section lying along an $x$ axis is divided into five segments of equal lengths. (a) Assume that $R_1 = R_3$, and rank the segments according to the magnitude of the average electric

![Figure 27-18](image1.png)

**Figure 27-18** Questions 1 and 2.

![Figure 27-19](image2.png)

**Figure 27-19** Question 4.
field in them, greatest first. (b) Now assume that \( R_1 > R_2 \) and then again rank the segments. (c) What is the direction of the electric field along the \( x \) axis?

5 For each circuit in Fig. 27-20, are the resistors connected in series, in parallel, or neither?

\[ \text{Figure 27-20 Question 5.} \]

6 *Res-monster maze.* In Fig. 27-21, all the resistors have a resistance of 4.0 \( \Omega \) and all the (ideal) batteries have an emf of 4.0 V. What is the current through resistor \( R \)? (If you can find the proper loop through this maze, you can answer the question with a few seconds of mental calculation.)

\[ \text{Figure 27-21 Question 6.} \]

7 A resistor \( R_1 \) is wired to a battery, then resistor \( R_2 \) is added in series. Are (a) the potential difference across \( R_1 \) and (b) the current \( i_i \) through \( R_1 \) now more than, less than, or the same as previously? (c) Is the equivalent resistance \( R_{12} \) of \( R_1 \) and \( R_2 \) more than, less than, or equal to \( R_1 \)?

8 What is the equivalent resistance of three resistors, each of resistance \( R \), if they are connected to an ideal battery (a) in series with one another and (b) in parallel with one another? (c) Is the potential difference across the series arrangement greater than, less than, or equal to that across the parallel arrangement?

9 Two resistors are wired to a battery. (a) In which arrangement, parallel or series, are the potential differences across each resistor and across the equivalent resistance all equal? (b) In which arrangement are the currents through each resistor and through the equivalent resistance all equal?

10 *Cap-monster maze.* In Fig. 27-22, all the capacitors have a capacitance of 6.0 \( \mu \text{F} \) and all the batteries have an emf of 10 V. What is the charge on capacitor \( C \)? (If you can find the proper loop through this maze, you can answer the question with a few seconds of mental calculation.)

11 Initially, a single resistor \( R_1 \) is wired to a battery. Then resistor \( R_2 \) is added in parallel. Are (a) the potential difference across \( R_1 \) and (b) the current \( i_i \) through \( R_1 \) now more than, less than, or the same as previously? (c) Is the equivalent resistance \( R_{12} \) of \( R_1 \) and \( R_2 \) more than, less than, or equal to \( R_1 \)? (d) Is the total current through \( R_1 \) and \( R_2 \) together more than, less than, or equal to the current through \( R_1 \) previously?

12 After the switch in Fig. 27-15 is closed on point \( a \), there is current \( i \) through resistance \( R \). Figure 27-23 gives that current for four sets of values of \( R \) and capacitance \( C \): (1) \( R_0 \) and \( C_0 \), (2) \( 2R_0 \) and \( C_0 \), (3) \( R_0 \) and \( 2C_0 \), (4) \( 2R_0 \) and \( 2C_0 \). Which set goes with which curve?

13 Figure 27-24 shows three sections of circuit that are to be connected in turn to the same battery via a switch as in Fig. 27-15. The resistors are all identical, as are the capacitors. Rank the sections according to (a) the final (equilibrium) charge on the capacitor and (b) the time required for the capacitor to reach 50% of its final charge, greatest first.
Module 27-1 Single-Loop Circuits

1. In Fig. 27-25, the ideal batteries have emfs $\varepsilon_1 = 12 \, \text{V}$ and $\varepsilon_2 = 6.0 \, \text{V}$. What are (a) the current, the dissipation rate in (b) resistor 1 (4.0 $\Omega$) and (c) resistor 2 (8.0 $\Omega$), and the energy transfer rate in (d) battery 1 and (e) battery 2? Is energy being supplied or absorbed by (f) battery 1 and (g) battery 2?

2. In Fig. 27-26, the ideal batteries have emfs $\varepsilon_1 = 150 \, \text{V}$ and $\varepsilon_2 = 50 \, \text{V}$ and the resistances are $R_1 = 3.0 \, \Omega$ and $R_2 = 2.0 \, \Omega$. If the potential at $P$ is 100 V, what is it at $Q$?

3. A car battery with a 12 V emf and an internal resistance of 0.040 $\Omega$ is being charged with a current of 50 A. What are (a) the potential difference $V$ across the terminals, (b) the rate $P_t$ of energy dissipation inside the battery, and (c) the rate $P_{en}$ of energy conversion to chemical form? When the battery is used to supply 50 A to the starter motor, what are (d) $V$ and (e) $P_t$?

4. Figure 27-27 shows a circuit of four resistors that are connected to a larger circuit. The graph below the circuit shows the electric potential $V(x)$ as a function of position $x$ along the lower branch of the circuit, through resistor 4; the potential $V_A$ is 12.0 V. The graph above the circuit shows the electric potential $V(x)$ versus position $x$ along the upper branch of the circuit, through resistors 1, 2, and 3; the potential differences are $\Delta V_A = 2.00 \, \text{V}$ and $\Delta V_C = 5.00 \, \text{V}$. Resistor 3 has a resistance of 200 $\Omega$. What is the resistance of (a) resistor 1 and (b) resistor 2?

5. A 5.0 A current is set up in a circuit for 6.0 min by a rechargeable battery with a 6.0 V emf. By how much is the chemical energy of the battery reduced?

6. A standard flashlight battery can deliver about 2.0 W-h of energy before it runs down. (a) If a battery costs US$0.80, what is the cost of operating a 100 W lamp for 8.0 h using batteries? (b) What is the cost if energy is provided at the rate of US$0.06 per kilowatt-hour?

7. A wire of resistance 5.0 $\Omega$ is connected to a battery whose emf $\varepsilon$ is 2.0 V and whose internal resistance is 1.0 $\Omega$. In 2.0 min, how much energy is (a) transferred from chemical form in the battery, (b) dissipated as thermal energy in the wire, and (c) dissipated as thermal energy in the battery?

8. A certain car battery with a 12.0 V emf has an initial charge of 120 A-h. Assuming that the potential across the terminals stays constant until the battery is completely discharged, for how many hours can it deliver energy at the rate of 100 W?

9. In electron-volts, how much work does an ideal battery with a 12.0 V emf do on an electron that passes through the battery from the positive to the negative terminal? (b) If $3.40 \times 10^{18}$ electrons pass through each second, what is the power of the battery in watts?

10. In Fig. 27-28, what value must $R$ have if the current in the circuit is to be 1.0 mA? Take $\varepsilon_1 = 2.0 \, \text{V}$, $\varepsilon_2 = 3.0 \, \text{V}$, and $r_1 = r_2 = 3.0 \, \Omega$. (a) What is the rate at which thermal energy appears in $R$?

11. In Fig. 27-29, circuit section $AB$ absorbs energy at a rate of 50 W when current $i = 1.0 \, \text{A}$ through it is in the indicated direction. Resistance $R = 2.0 \, \Omega$. (a) What is the potential difference between $A$ and $B$? Emf device $X$ lacks internal resistance. (b) What is its emf? (c) Is point $B$ connected to the positive terminal of $X$ or to the negative terminal?

12. Figure 27-30 shows a resistor of resistance $R = 6.00 \, \Omega$ connected to an ideal battery of emf $\varepsilon = 12.0 \, \text{V}$ by means of two copper wires. Each wire has length 20.0 cm and radius 1.00 mm. In dealing with such circuits in this chapter, we generally neglect the potential differences along the wires and the transfer of energy to thermal energy in them. Check the validity of this neglect for the circuit of Fig. 27-30: What is the potential difference across (a) the resistor and (b) each of the two sections of wire? At what rate is energy lost to thermal energy in (c) the resistor and (d) each section of wire?

13. A 10-km-long underground cable extends east to west and consists of two parallel wires, each of which has resistance 13 $\Omega$/km. An electrical short develops at distance $x$ from the west end when
a conducting path of resistance $R$ connects the wires (Fig. 27-31). The resistance of the wires and the short is then 100 $\Omega$ when measured from the east end and 200 $\Omega$ when measured from the west end. What are (a) $x$ and (b) $R$?

**14** In Fig. 27-32a, both batteries have emf $\overline{V}$ = 1.20 V and the external resistance $R$ is a variable resistor. Figure 27-32b gives the electric potentials $V$ between the terminals of each battery as functions of $R$: Curve 1 corresponds to battery 1, and curve 2 corresponds to battery 2. The horizontal scale is set by $R_1 = 0.20$ $\Omega$. What is the internal resistance of (a) battery 1 and (b) battery 2?

![Figure 27-32 Problem 14.](image)

**15 ILW** The current in a single-loop circuit with one resistance $R$ is 5.0 A. When an additional resistance of 2.0 $\Omega$ is inserted in series with $R$, the current drops to 4.0 A. What is $R$?

**16** A solar cell generates a potential difference of 0.10 V when a 1000 $\Omega$ resistor is connected across it, and a potential difference of 0.15 V when a 1000 $\Omega$ resistor is substituted. What are the (a) internal resistance and (b) emf of the solar cell? (c) The area of the cell is 5.0 $\text{cm}^2$, and the rate per unit area at which it receives energy from light is 2.0 $\text{mW/cm}^2$. What is the efficiency of the cell for converting light energy to thermal energy in the 1000 $\Omega$ external resistor?

**17 SSM** In Fig. 27-33, battery 1 has emf $\overline{V}_1 = 12.0$ V and internal resistance $r_1 = 0.016$ $\Omega$ and battery 2 has emf $\overline{V}_2 = 12.0$ V and internal resistance $r_2 = 0.012$ $\Omega$. The batteries are connected in series with an external resistance $R$. (a) What $R$ value makes the terminal-to-terminal potential difference of one of the batteries zero? (b) Which battery is that?

**Module 27-2 Multiloop Circuits**

**18** In Fig. 27-9, what is the potential difference $V_{d} - V_{c}$ between points $d$ and $c$ if $\overline{V}_1 = 4.0$ V, $\overline{V}_2 = 1.0$ V, $R_1 = R_2 = 10$ $\Omega$, and $R_3 = 5.0$ $\Omega$, and the battery is ideal?

**19** A total resistance of 3.00 $\Omega$ is to be produced by connecting an unknown resistance to a 12.0 $\Omega$ resistance. (a) What must be the value of the unknown resistance, and (b) should it be connected in series or in parallel?

**20** When resistors 1 and 2 are connected in series, the equivalent resistance is 16.0 $\Omega$. When they are connected in parallel, the equivalent resistance is 3.0 $\Omega$. What are (a) the smaller resistance and (b) the larger resistance of these two resistors?

**21** Four 18.0 $\Omega$ resistors are connected in parallel across a 25.0 V ideal battery. What is the current through the battery?

**22** Figure 27-34 shows five 5.00 $\Omega$ resistors. Find the equivalent resistance between points (a) $F$ and $H$ and (b) $F$ and $G$. (Hint: For each pair of points, imagine that a battery is connected across the pair.)

**23** In Fig. 27-35, $R_1 = 100$ $\Omega$, $R_2 = 50$ $\Omega$, and the ideal batteries have emfs $\overline{V}_1 = 6.0$ V, $\overline{V}_2 = 5.0$ V, and $\overline{V}_3 = 4.0$ V. Find (a) the current in resistor 1, (b) the current in resistor 2, and (c) the potential difference between points $a$ and $b$.

**24** In Fig. 27-36, $R_1 = R_2 = 4.00$ $\Omega$ and $R_3 = 2.50$ $\Omega$. Find the equivalent resistance between points $D$ and $E$. (Hint: Imagine that a battery is connected across those points.)

**25 SSM** Nine copper wires of length $l$ and diameter $d$ are connected in parallel to form a single composite conductor of resistance $R$. What must be the diameter $D$ of a single copper wire of length $l$ if it is to have the same resistance?

**26** Figure 27-37 shows a battery connected across a uniform resistor $R_0$. A sliding contact can move across the resistor from $x = 0$ at the left to $x = 10$ cm at the right. Moving the contact changes how much resistance is to the left of the contact and how much is to the right. Find the rate at which energy is dissipated in resistor $R$ as a function of $x$. Plot the function for $\overline{V} = 50$ V, $R = 2000$ $\Omega$, and $R_0 = 100$ $\Omega$.

**27** *Side flash.* Figure 27-38 indicates one reason no one should stand under a tree during a lightning storm. If lightning comes down the side of the tree, a portion can jump over to the person, especially if the current on the tree reaches a dry region on the bark and thereafter must travel through air to reach the ground. In the figure, part of the lightning jumps through distance $d$ in air and then travels through the person (who has negligible resistance relative to that of air because of the highly conducting salty fluids within the body). The rest of the current travels through air alongside the tree, for a distance $h$. If $d/h = 0.400$ and the total current is $I = 5000$ A, what is the current through the person?

**28** The ideal battery in Fig. 27-39a has emf $\overline{V} = 6.0$ V. Plot 1 in Fig. 27-39b gives the electric potential difference $V$ that can appear across resistor 1 versus the current $i$ in that resistor when the resistor...
is individually tested by putting a variable potential across it. The scale of the V axis is set by $V_s = 18.0 \text{ V}$, and the scale of the i axis is set by $i_s = 3.00 \text{ mA}$. Plots 2 and 3 are similar plots for resistors 2 and 3, respectively, when they are individually tested by putting a variable potential across them. What is the current in resistor 2 in the circuit of Fig. 27-39?

![Figure 27-39 Problem 28.](image)

**29** In Fig. 27-40, $R_1 = 6.00 \Omega$, $R_2 = 18.0 \Omega$, and the ideal battery has emf $\varepsilon = 12.0 \text{ V}$. What are the (a) size and (b) direction (left or right) of current $i_1$? (c) How much energy is dissipated by all four resistors in 1.00 min?

**30** In Fig. 27-41, the ideal batteries have emfs $\varepsilon_1 = 10.0 \text{ V}$ and $\varepsilon_2 = 0.500\varepsilon_1$, and the resistances are each 4.00 $\Omega$. What is the current in (a) resistance 2 and (b) resistance 3?

**31** In Fig. 27-42, the ideal batteries have emfs $\varepsilon_1 = 5.0 \text{ V}$ and $\varepsilon_2 = 12 \text{ V}$, the resistances are each 2.0 $\Omega$, and the potential is defined to be zero at the grounded point of the circuit. What are potentials (a) $V_1$ and (b) $V_2$ at the indicated points?

**32** Both batteries in Fig. 27-43a are ideal. Emf $\varepsilon_1$ of battery 1 has a fixed value, but emf $\varepsilon_2$ of battery 2 can be varied between 1.0 $\text{ V}$ and 10 $\text{ V}$. The plots in Fig. 27-43b give the currents through the two batteries as a function of $\varepsilon_2$. The vertical scale is set by $i_s = 0.20 \text{ A}$. You must decide which plot corresponds to which battery, but for both plots, a negative current occurs when the direction of the current through the battery is opposite the direction of that battery’s emf. What are (a) emf $\varepsilon_1$, (b) resistance $R_1$, and (c) resistance $R_2$?

**33** In Fig. 27-44, the current in resistance 6 is $i_6 = 1.40 \text{ A}$ and the resistances are $R_1 = R_3 = R_5 = 2.00 \Omega$, $R_4 = 16.0 \Omega$, $R_5 = 8.00 \Omega$, and $R_6 = 4.00 \Omega$. What is the emf of the ideal battery?

![Figure 27-44 Problem 33.](image)

**34** The resistances in Figs. 27-45a and b are all 6.0 $\Omega$, and the batteries are ideal 12 $\text{ V}$ batteries. (a) When switch S in Fig. 27-45a is closed, what is the change in the electric potential $V_1$ across resistor 1, or does $V_1$ remain the same? (b) When switch S in Fig. 27-45b is closed, what is the change in $V_1$ across resistor 1, or does $V_1$ remain the same?

![Figure 27-45 Problem 34.](image)

**35** In Fig. 27-46, $\varepsilon = 12.0 \text{ V}$, $R_1 = 2000 \Omega$, $R_2 = 3000 \Omega$, and $R_3 = 4000 \Omega$. What are the potential differences (a) $V_A - V_B$, (b) $V_B - V_C$, (c) $V_C - V_D$, and (d) $V_D - V_E$?

**36** In Fig. 27-47, $\varepsilon_1 = 6.00 \text{ V}$, $\varepsilon_2 = 12.0 \text{ V}$, $R_1 = 100 \Omega$, $R_2 = 200 \Omega$, and $R_3 = 300 \Omega$. One point of the circuit is grounded ($V = 0$). What are the (a) size and (b) direction (up or down) of the current through resistance 1, the (c) size and (d) direction (left or right) of the current through resistance 2, and the (e) size and (f) direction of the current through resistance 3? (g) What is the electric potential at point A?

**37** In Fig. 27-48, the resistances are $R_1 = 2.00 \Omega$, $R_2 = 5.00 \Omega$, and the battery is ideal. What value of $R_3$ maximizes the dissipation rate in resistance 3?

**38** Figure 27-49 shows a section of a circuit. The resistances are $R_1 = 2.0 \Omega$, $R_2 = 4.0 \Omega$, and $R_3 = 6.0 \Omega$, and the indicated current is $i = 6.0 \text{ A}$. The electric potential difference between points A and B that connect the section to the rest of the circuit is $V_A - V_B = 78 \text{ V}$. (a) Is the device represented by “Box” absorbing or providing energy to the circuit, and (b) at what rate?

![Figure 27-49 Problem 38.](image)
39. In Fig. 27-50, two batteries with an emf $\mathcal{E} = 12.0 \text{ V}$ and an internal resistance $r = 0.300 \text{ } \Omega$ are connected in parallel across a resistance $R$. (a) For what value of $R$ is the dissipation rate in the resistor a maximum? (b) What is that maximum?

40. Two identical batteries of emf $\mathcal{E} = 12.0 \text{ V}$ and internal resistance $r = 0.200 \text{ } \Omega$ are to be connected to an external resistance $R$, either in parallel (Fig. 27-50) or in series (Fig. 27-51). If $R = 2.00r$, what is the current $i$ in the external resistance in the (a) parallel and (b) series arrangements? (c) For which arrangement is $i$ greater? If $R = r/2.00$, what is $i$ in the external resistance in the (d) parallel arrangement and (e) series arrangement? (f) For which arrangement is $i$ greater now?

41. In Fig. 27-41, $\mathcal{E}_1 = 3.00 \text{ V}$, $\mathcal{E}_2 = 1.00 \text{ V}$, $R_1 = 4.00 \text{ } \Omega$, $R_2 = 2.00 \text{ } \Omega$, $R_3 = 5.00 \text{ } \Omega$, and both batteries are ideal. What is the rate at which energy is dissipated in (a) $R_1$, (b) $R_2$, and (c) $R_3$? What is the power of (d) battery 1 and (e) battery 2?

42. In Fig. 27-52, an array of $n$ parallel resistors is connected in series to a resistor and an ideal battery. All the resistors have the same resistance. If an identical resistor were added in parallel to the parallel array, the current through the battery would change by 1.25%. What is the value of $n$?

43. You are given a number of 10 $\text{ } \Omega$ resistors, each capable of dissipating only 1.0 W without being destroyed. What is the minimum number of such resistors that you need to combine in series or in parallel to make a 10 $\text{ } \Omega$ resistance that is capable of dissipating at least 5.0 W?

44. In Fig. 27-53, $R_1 = 100 \text{ } \Omega$, $R_2 = R_3 = 50.0 \text{ } \Omega$, $R_4 = 75.0 \text{ } \Omega$, and the ideal battery has emf $\mathcal{E} = 6.00 \text{ V}$. (a) What is the equivalent resistance? What is $i$ in (b) resistance 1, (c) resistance 2, (d) resistance 3, and (e) resistance 4?

45. In Fig. 27-54, the resistances are $R_1 = 1.0 \text{ } \Omega$ and $R_2 = 2.0 \text{ } \Omega$, and the ideal batteries have emfs $\mathcal{E}_1 = 2.0 \text{ V}$ and $\mathcal{E}_2 = \mathcal{E}_3 = 4.0 \text{ V}$. What are the (a) size and (b) direction of the current in battery 1, the (c) size and (d) direction of the current in battery 2, and the (e) size and (f) direction of the current in battery 3? (g) What is the potential difference $V_a - V_b$?

46. In Fig. 27-55a, resistor 3 is a variable resistor and the ideal battery has emf $\mathcal{E} = 12.0 \text{ V}$. Figure 27-55b gives the current $i$ through the battery as a function of $R_3$. The horizontal scale is set by $R_4 = 20 \text{ } \Omega$. What is the asymptote of 2.0 mA as $R_3 \to \infty$. What are (a) resistance $R_1$ and (b) resistance $R_2$?

47. A copper wire of radius $a = 0.250 \text{ mm}$ has an aluminum jacket of outer radius $b = 0.380 \text{ mm}$. There is a current $i = 2.00 \text{ A}$ in the composite wire. Using Table 26-1, calculate the current in (a) the copper and (b) the aluminum. (c) If a potential difference $V = 12.0 \text{ V}$ between the ends maintains the current, what is the length of the composite wire?

48. In Fig. 27-53, the resistors have the values $R_1 = 7.00 \text{ } \Omega$, $R_2 = 12.0 \text{ } \Omega$, and $R_3 = 4.00 \text{ } \Omega$, and the ideal battery’s emf is $\mathcal{E} = 24.0 \text{ V}$. For what value of $R_4$ will the rate at which the battery transfers energy to the resistors equal (a) 60.0 W; (b) the maximum possible rate $P_{\text{max}}$; and (c) the minimum possible rate $P_{\text{min}}$? What are (d) $P_{\text{max}}$ and (e) $P_{\text{min}}$?

Module 27-3 The Ammeter and the Voltmeter

49. (a) In Fig. 27-56, what current does the ammeter read if $\mathcal{E} = 5.0 \text{ V}$ (ideal battery), $R_1 = 2.0 \text{ } \Omega$, $R_2 = 4.0 \text{ } \Omega$, and $R_3 = 6.0 \text{ } \Omega$? (b) The ammeter and battery are now interchanged. Show that the ammeter reading is unchanged.

50. In Fig. 27-57, $R_1 = 2.00R$, the ammeter resistance is zero, and the battery is ideal. What multiple of $\mathcal{E}/R$ gives the current in the ammeter?

51. In Fig. 27-58, a voltmeter of resistance $R_V = 300 \text{ } \Omega$ and an ammeter of resistance $R_A = 3.00 \text{ } \Omega$ are being used to measure a resistance $R$ in a circuit that also contains a resistance $R_0 = 100 \text{ } \Omega$ and an ideal battery with an emf of $\mathcal{E} = 12.0 \text{ V}$. Resistance $R$ is given by $R = V/i$, where $V$ is the potential across $R$ and $i$ is the ammeter reading. The voltmeter reading is $V'$, which is $V$ plus the potential difference across the ammeter. Thus, the ratio of the two meter readings is not $R$ but only an apparent resistance $R' = V'/i$. If $R = 85.0 \text{ } \Omega$, what are (a) the ammeter reading, (b) the voltmeter reading, and (c) $R'$? (d) If $R_A$ is decreased, does the difference between $R'$ and $R$ increase, decrease, or remain the same?

52. A simple ohmmeter is made by connecting a 1.50 V flashlight battery in series with a resistance $R$ and an ammeter that
reads from 0 to 1.00 mA, as shown in Fig. 27-59. Resistance $R$ is adjusted so that when the clip leads are shorted together, the meter deflects to its full-scale value of 1.00 mA. What external resistance across the leads results in a deflection of (a) 10.0%, (b) 50.0%, and (c) 90.0% of full scale? (d) If the ammeter has a resistance of 20.0 $\Omega$ and the internal resistance of the battery is negligible, what is the value of $R$?

**53** In Fig. 27-14, assume that $E = 3.0$ V, $r = 100$ $\Omega$, $R_1 = 250$ $\Omega$, and $R_2 = 300$ $\Omega$. If the voltmeter resistance $R_V$ is 5.0 k$\Omega$, what percent error does it introduce into the measurement of the potential difference across $R_1$? Ignore the presence of the ammeter.

**54** When the lights of a car are switched on, an ammeter in series with them reads 10.0 A and a voltmeter connected across them reads 12.0 V (Fig. 27-60). When the electric starting motor is turned on, the ammeter reading drops to 8.00 A and the lights dim somewhat. If the internal resistance of the battery is 0.0500 $\Omega$ and that of the ammeter is negligible, what are (a) the emf of the battery and (b) the current through the starting motor when the lights are on?

**55** In Fig. 27-61, $R_2$ is to be adjusted in value by moving the sliding contact across it until points $a$ and $b$ are brought to the same potential. (One tests for this condition by momentarily connecting a sensitive ammeter between $a$ and $b$; if these points are at the same potential, the ammeter will not deflect.) Show that when this adjustment is made, the following relation holds: $R_2 = R_1 R_2 / R_1$. An unknown resistance ($R_2$) can be measured in terms of a standard ($R_1$) using this device, which is called a Wheatstone bridge.

**56** In Fig. 27-62, a voltmeter of resistance $R_V = 300$ $\Omega$ and an ammeter of resistance $R_A = 3.00$ $\Omega$ are being used to measure a resistance $R$ in a circuit that also contains a resistance $R_0 = 100$ $\Omega$ and an ideal battery of emf $E = 12.0$ V. Resistance $R$ is given by $R = V/i$, where $V$ is the voltmeter reading and $i$ is the current in resistance $R$. However, the ammeter reading is not $i$ but rather $i'$, which is $i$ plus the current through the voltmeter. Thus, the ratio of the two meter readings is not $R$ but only an apparent resistance $R' = V/i'$. If $R = 85.0$ $\Omega$, what are (a) the ammeter reading, (b) the voltmeter reading, and (c) $R'$? (d) If $R_V$ is increased, does the difference between $R'$ and $R$ increase, decrease, or remain the same?

**57** Switch S in Fig. 27-63 is closed at time $t = 0$, to begin charging an initially uncharged capacitor of capacitance $C = 15.0 \mu F$ through a resistor of resistance $R = 20.0$ $\Omega$. At what time is the potential across the capacitor equal to that across the resistor?

**58** In an RC series circuit, emf $E = 12.0$ V, resistance $R = 1.40$ M$\Omega$, and capacitance $C = 1.80 \mu F$. (a) Calculate the time constant. (b) Find the maximum charge that will appear on the capacitor during charging. (c) How long does it take for the charge to build up to 16.0 $\mu C$?

**59** SSM What multiple of the time constant $\tau$ gives the time taken by an initially uncharged capacitor in an RC series circuit to be charged to 99.0% of its final charge?

**60** A capacitor with initial charge $q_0$ is discharged through a resistor. What multiple of the time constant $\tau$ gives the time the capacitor takes to lose (a) the first one-third of its charge and (b) two-thirds of its charge?

**61** IWW A 15.0 k$\Omega$ resistor and a capacitor are connected in series, and then a 12.0 V potential difference is suddenly applied across them. The potential difference across the capacitor rises to 5.00 V in 1.30 $\mu$s. (a) Calculate the time constant of the circuit. (b) Find the capacitance of the capacitor.

**62** Figure 27-64 shows the circuit of a flashing lamp, like those attached to barrels at highway construction sites. The fluorescent lamp L (of negligible capacitance) is connected in parallel across the capacitor $C$ of an RC circuit. There is a current through the lamp only when the potential difference across it reaches the breakdown voltage $V_l$; then the capacitor discharges completely through the lamp and the lamp flashes briefly. For a lamp with breakdown voltage $V_l = 720$ V, wired to a 95.0 V ideal battery and a 0.150 $\mu F$ capacitor, what resistance $R$ is needed for two flashes per second?

**63** SSM WWW In the circuit of Fig. 27-65, $E = 1.2$ kV, $C = 6.5 \mu F$, $R_1 = R_2 = R_3 = 0.73$ M$\Omega$. With $C$ completely uncharged, switch S is suddenly closed (at $t = 0$). At $t = 0$, what are (a) current $i_1$ in resistor 1, (b) current $i_2$ in resistor 2, and (c) current $i_3$ in resistor 3? At $t = \infty$ (that is, after many time constants), what are (d) $i_1$, (e) $i_2$, and (f) $i_3$? What is the potential difference $V_2$ across resistor 2 at (g) $t = 0$ and (h) $t = \infty$? (i) Sketch $V_2$ versus $t$ between these two extreme times.

**64** A capacitor with an initial potential difference of 100 V is discharged through a resistor when a switch between them is closed at $t = 0$. At $t = 10.0$ s, the potential difference across the capacitor is 1.00 V. (a) What is the time constant of the circuit? (b) What is the potential difference across the capacitor at $t = 17.0$ s?

**65** In Fig. 27-66, $R_1 = 10.0$ k$\Omega$, $R_2 = 15.0$ k$\Omega$, $C = 0.400 \mu F$, and the
ideal battery has emf $\phi = 20.0$ V. First, the switch is closed a long time so that the steady state is reached. Then the switch is opened at time $t = 0$. What is the current in resistor 2 at $t = 4.00$ ms?

66 Figure 27-67 displays two circuits with a charged capacitor that is to be discharged through a resistor when a switch is closed. In Fig. 27-67a, $R_1 = 20.0$ $\Omega$ and $C_1 = 5.00$ $\mu$F. In Fig. 27-67b, $R_2 = 10.0$ $\Omega$ and $C_2 = 8.00$ $\mu$F. The ratio of the initial charges on the two capacitors is $q_{02}/q_{01} = 1.50$. At time $t = 0$, both switches are closed. At what time do the two capacitors have the same charge?

67 The potential difference between the plates of a leaky capacitor drops to one-fourth its initial value in 2.0 s. What is the time the discharge starts? Find an expression that gives, as a function of $C$ (external) resistance of 4.0 $\Omega$.

Problem 66. What is the current through the capacitor, (c) thermal energy is appearing in the resistor, and (d) energy is being delivered by the battery?

Additional Problems

70 Each of the six real batteries in Fig. 27-68 has an emf of 20 V and a resistance of 4.0 $\Omega$. (a) What is the current through the (external) resistance $R = 4.0$ $\Omega$? (b) What is the potential difference across each battery? (c) What is the power of each battery? (d) At what rate does each battery transfer energy to internal thermal energy?

71 In Fig. 27-69, $R_1 = 20.0$ $\Omega$, $R_2 = 10.0$ $\Omega$, and the ideal battery has emf $\phi = 120$ V. What is the current at point a if we close (a) only switch $S_1$, (b) only switches $S_2$ and $S_3$, and (c) all three switches?

72 In Fig. 27-70, the ideal battery has emf $\phi = 30.0$ V, and the resistances are $R_1 = R_2 = 14$ $\Omega$, $R_3 = 6.0$ $\Omega$, $R_4 = 2.0$ $\Omega$, and $R_5 = 1.5$ $\Omega$. What are currents (a) $i_2$, (b) $i_3$, (c) $i_4$, (d) $i_5$, and (e) $i_6$?

73 Wires A and B, having equal lengths of 40.0 m and equal diameters of 2.60 mm, are connected in series. A potential difference of 60.0 V is applied between the ends of the composite wire. The resistances are $R_A = 0.127$ $\Omega$ and $R_B = 0.729$ $\Omega$. For wire A, what are (a) magnitude $J$ of the current density and (b) potential difference $V$? (c) Of what type material is wire A made (see Table 26-I)? For wire B, what are (d) $J$ and (e) $V$? (f) Of what type material is B made?

74 What are the (a) size and (b) direction (up or down) of current $i$ in Fig. 27-71, where all resistances are 4.0 $\Omega$ and all batteries are ideal and have an emf of 10 V? (Hint: This can be answered using only mental calculation.)
its power? (g) Does battery 3 supply or absorb energy, and (h) what is its power?

Figure 27-72 Problem 76.

77 SSM A temperature-stable resistor is made by connecting a resistor made of silicon in series with one made of iron. If the required total resistance is 1000 ohms in a wide temperature range around 20°C, what should be the resistance of the (a) silicon resistor and (b) iron resistor? (See Table 26-1.)

78 In Fig. 27-14, assume that ε = 5.0 V, r = 2.0 Ω, R1 = 5.0 Ω, and R2 = 4.0 Ω. If the ammeter resistance Ra is 0.10 Ω, what percent error does it introduce into the measurement of the current? Assume that the voltmeter is not present.

79 SSM An initially uncharged capacitor C is fully charged by a device of constant emf ε connected in series with a resistor R. (a) Show that the final energy stored in the capacitor is half the energy supplied by the emf device. (b) By direct integration of dP/dt over the charging time, show that the thermal energy dissipated by the resistor is also half the energy supplied by the emf device.

80 In Fig. 27-73, R1 = 5.00 Ω, R2 = 10.0 Ω, R3 = 15.0 Ω, C1 = 5.00 μF, C2 = 10.0 μF, and the ideal battery has emf ε = 20.0 V. Assuming that the circuit is in the steady state, what is the total energy stored in the two capacitors?

81 In Fig. 27-5a, find the potential difference across R2 if ε = 12 V, R1 = 3.0 Ω, R2 = 4.0 Ω, and R3 = 5.0 Ω.

82 In Fig. 27-8a, calculate the potential difference between a and c by considering a path that contains R, r1, and ε1.

83 SSM A controller on an electronic arcade game consists of a variable resistor connected across the plates of a 0.220 μF capacitor. The capacitor is charged to 5.00 V, then discharged through the resistor. The time for the potential difference across the plates to decrease to 0.800 V is measured by a clock inside the game. If the range of discharge times that can be handled effectively is from 10.0 ms to 6.00 ms, what should be the (a) lower value and (b) higher value of the resistance range of the resistor?

84 An automobile gasoline gauge is shown schematically in Fig. 27-74. The indicator (on the dashboard) has a resistance of 10 Ω. The tank unit is a float connected to a variable resistor whose resistance varies linearly with the volume of gasoline. The resistance is 140 Ω when the tank is empty and 20 Ω when the tank is full. Find the current in the circuit when the tank is (a) empty, (b) half-full, and (c) full. Treat the battery as ideal.

85 SSM The starting motor of a car is turning too slowly, and the mechanic has to decide whether to replace the motor, the cable, or the battery. The car’s manual says that the 12 V battery should have no more than 0.020 Ω internal resistance, the motor no more than 0.200 Ω resistance, and the cable no more than 0.040 Ω resistance. The mechanic turns on the motor and measures 11.4 V across the battery, 3.0 V across the cable, and a current of 50 A. Which part is defective?

86 Two resistors R1 and R2 may be connected either in series or in parallel across an ideal battery with emf ε. We desire the rate of energy dissipation of the parallel combination to be five times that of the series combination. If R1 = 100 Ω, what are the (a) smaller and (b) larger of the two values of R2 that result in that dissipation rate?

87 The circuit of Fig. 27-75 shows a capacitor, two ideal batteries, two resistors, and a switch S. Initially S has been open for a long time. If it is then closed for a long time, what is the change in the charge on the capacitor? Assume C = 10 μF, ε1 = 1.0 V, ε2 = 3.0 V, R1 = 0.20 Ω, and R2 = 0.40 Ω.

88 In Fig. 27-41, R1 = 10.0 Ω, R2 = 20.0 Ω, and the ideal batteries have emfs ε1 = 20.0 V and ε2 = 50.0 V. What value of R3 results in no current through battery 1?

89 In Fig. 27-76, R = 10 Ω. What is the equivalent resistance between points A and B? (Hint: This circuit section might look simpler if you first assume that points A and B are connected to a battery.)

90 (a) In Fig. 27-4a, show that the rate at which energy is dissipated in R as thermal energy is a maximum when R = r. (b) Show that this maximum power is P = ε2/4r.

91 In Fig. 27-77, the ideal batteries have emfs ε1 = 12.0 V and ε2 = 4.00 V, and the resistances are each 4.00 Ω. What are the (a) size and (b) direction (up or down) of i1, and the (c) size and (d) direction of i2? (e) Does battery 1 supply or absorb energy, and (f) what is its energy transfer rate? (g) Does battery 2 supply or absorb energy, and (h) what is its energy transfer rate?

92 Figure 27-78 shows a portion of a circuit through which there is a current I = 6.00 A. The resistances are R1 = R2 = 2.00Ω, R3 = 2.00Ω, R4 = 4.00 Ω. What is the current i1 through resistor 1?

93 Thermal energy is to be generated in a 0.10 Ω resistor at the rate of

Figure 27-78 Problem 92.
10 W by connecting the resistor to a battery whose emf is 1.5 V. (a) What potential difference must exist across the resistor? (b) What must be the internal resistance of the battery?

94 Figure 27-79 shows three 20.0 Ω resistors. Find the equivalent resistance between points (a) A and B, (b) A and C, and (c) B and C. (Hint: Imagine that a battery is connected between a given pair of points.)

95 A 120 V power line is protected by a 15 A fuse. What is the maximum number of 500 W lamps that can be simultaneously operated in parallel on this line without “blowing” the fuse because of an excess of current?

96 Figure 27-63 shows an ideal battery of emf \( \varepsilon = 12 \) V, a resistor of resistance \( R = 4.0 \) Ω, and an uncharged capacitor of capacitance \( C = 4.0 \) μF. After switch S is closed, what is the current through the resistor when the charge on the capacitor is \( 8.0 \) μC?

97 SSM A group of \( N \) identical batteries of emf \( \varepsilon \) and internal resistance \( r \) may be connected all in series (Fig. 27-80a) or all in parallel (Fig. 27-80b) and then across a resistor \( R \). Show that both arrangements give the same current in \( R \) if \( R = r \).

98 SSM In Fig. 27-48, \( R_1 = R_2 = 10.0 \) Ω, and the ideal battery has emf \( \varepsilon = 12.0 \) V. (a) What value of \( R_3 \) maximizes the rate at which the battery supplies energy and (b) what is that maximum rate?

99 SSM In Fig. 27-66, the ideal battery has emf \( \varepsilon = 30 \) V, the resistances are \( R_1 = 20 \) kΩ and \( R_2 = 10 \) kΩ, and the capacitor is uncharged. When the switch is closed at time \( t = 0 \), what is the current in (a) resistance 1 and (b) resistance 2? (c) A long time later, what is the current in resistance 2?

100 In Fig. 27-81, the ideal batteries have emfs \( \varepsilon_1 = 20.0 \) V, \( \varepsilon_2 = 10.0 \) V, \( \varepsilon_3 = 5.00 \) V, and \( \varepsilon_4 = 5.00 \) V, and the resistances are each 2.00 Ω. What are the (a) size and (b) direction (left or right) of current \( i_1 \) and the (c) size and (d) direction of current \( i_2 \)? (This can be answered with only mental calculation.) (e) At what rate is energy being transferred in battery 4, and (f) is the energy being supplied or absorbed by the battery?

101 In Fig. 27-82, an ideal battery of emf \( \varepsilon = 12.0 \) V is connected to a network of resistances \( R_1 = 6.00 \) Ω, \( R_2 = 12.0 \) Ω, \( R_3 = 4.00 \) Ω, \( R_4 = 3.00 \) Ω, and \( R_5 = 5.00 \) Ω. What is the potential difference across resistance 5?

102 The following table gives the electric potential difference \( V_T \) across the terminals of a battery as a function of current \( i \) being drawn from the battery. (a) Write an equation that represents the relationship between \( V_T \) and \( i \). Enter the data into your graphing calculator and perform a linear regression fit of \( V_T \) versus \( i \). From the parameters of the fit, find (b) the battery’s emf and (c) its internal resistance.

<table>

103 In Fig. 27-83, \( \varepsilon_1 = 6.00 \) V, \( \varepsilon_2 = 12.0 \) V, \( R_1 = 200 \) Ω, and \( R_2 = 100 \) Ω. What are the (a) size and (b) direction (up or down) of the current through resistance 1, the (c) size and (d) direction of the current through resistance 2, and the (e) size and (f) direction of the current through battery 2?

104 A three-way 120 V lamp bulb that contains two filaments is rated for 100-200-300 W. One filament burns out. Afterward, the bulb operates at the same intensity (dissipates energy at the same rate) on its lowest as on its highest switch positions but does not operate at all on the middle position. (a) How are the two filaments wired to the three switch positions? What are the (b) smaller and (c) larger values of the filament resistances?

105 In Fig. 27-84, \( R_1 = R_2 = 2.0 \) Ω, \( R_3 = 4.0 \) Ω, \( R_4 = 3.0 \) Ω, \( R_5 = 1.0 \) Ω, and \( R_6 = R_7 = R_8 = 8.0 \) Ω, and the ideal batteries have emfs \( \varepsilon_1 = 16 \) V and \( \varepsilon_2 = 8.0 \) V. What are the (a) size and (b) direction (up or down) of current \( i_1 \) and the (c) size and (d) direction of current \( i_2 \)? What is the energy transfer rate in (e) battery 1 and (f) battery 2? Is energy being supplied or absorbed in (g) battery 1 and (h) battery 2?
Magnetic Fields

28-1 MAGNETIC FIELDS AND THE DEFINITION OF $\mathbf{B}$

Learning Objectives

After reading this module, you should be able to . . .

28.01 Distinguish an electromagnet from a permanent magnet.
28.02 Identify that a magnetic field is a vector quantity and thus has both magnitude and direction.
28.03 Explain how a magnetic field can be defined in terms of what happens to a charged particle moving through the field.
28.04 For a charged particle moving through a uniform magnetic field, apply the relationship between force magnitude $F_B$, charge $q$, speed $v$, field magnitude $B$, and the angle $\phi$ between the directions of the velocity vector $\mathbf{v}$ and the magnetic field vector $\mathbf{B}$.
28.05 For a charged particle sent through a uniform magnetic field, find the direction of the magnetic force $F_B$ by (1) applying the right-hand rule to find the direction of the cross product $\mathbf{v} \times \mathbf{B}$ and (2) determining what effect the charge $q$ has on the direction.
28.06 Find the magnetic force $F_B$ acting on a moving charged particle by evaluating the cross product $q(\mathbf{v} \times \mathbf{B})$ in unit-vector notation and magnitude-angle notation.
28.07 Identify that the magnetic force vector $F_B$ must always be perpendicular to both the velocity vector $\mathbf{v}$ and the magnetic field vector $\mathbf{B}$.
28.08 Identify the effect of the magnetic force on the particle's speed and kinetic energy.
28.09 Identify a magnet as being a magnetic dipole.
28.10 Identify that opposite magnetic poles attract each other and like magnetic poles repel each other.
28.11 Explain magnetic field lines, including where they originate and terminate and what their spacing represents.

Key Ideas

- When a charged particle moves through a magnetic field $\mathbf{B}$, a magnetic force acts on the particle as given by
  \[ F_B = q(\mathbf{v} \times \mathbf{B}), \]

  where $q$ is the particle’s charge (sign included) and $\mathbf{v}$ is the particle’s velocity.

- The right-hand rule for cross products gives the direction of $\mathbf{v} \times \mathbf{B}$. The sign of $q$ then determines whether $F_B$ is in the same direction as $\mathbf{v} \times \mathbf{B}$ or in the opposite direction.

- The magnitude of $F_B$ is given by
  \[ F_B = |q|vB \sin \phi, \]

  where $\phi$ is the angle between $\mathbf{v}$ and $\mathbf{B}$.

What Is Physics?

As we have discussed, one major goal of physics is the study of how an electric field can produce an electric force on a charged object. A closely related goal is the study of how a magnetic field can produce a magnetic force on a (moving) charged particle or on a magnetic object such as a magnet. You may already have a hint of what a magnetic field is if you have ever attached a note to a refrigerator door with a small magnet or accidentally erased a credit card by moving it near a magnet. The magnet acts on the door or credit card via its magnetic field.

The applications of magnetic fields and magnetic forces are countless and changing rapidly every year. Here are just a few examples. For decades, the entertainment industry depended on the magnetic recording of music and images on audiotape and videotape. Although digital technology has largely replaced
magnetic recording, the industry still depends on the magnets that control CD and DVD players and computer hard drives; magnets also drive the speaker cones in headphones, TVs, computers, and telephones. A modern car comes equipped with dozens of magnets because they are required in the motors for engine ignition, automatic window control, sunroof control, and windshield wiper control. Most security alarm systems, doorbells, and automatic door latches employ magnets. In short, you are surrounded by magnets.

The science of magnetic fields is physics; the application of magnetic fields is engineering. Both the science and the application begin with the question "What produces a magnetic field?"

What Produces a Magnetic Field?

Because an electric field $\vec{E}$ is produced by an electric charge, we might reasonably expect that a magnetic field $\vec{B}$ is produced by a magnetic charge. Although individual magnetic charges (called magnetic monopoles) are predicted by certain theories, their existence has not been confirmed. How then are magnetic fields produced? There are two ways.

One way is to use moving electrically charged particles, such as a current in a wire, to make an electromagnet. The current produces a magnetic field that can be used, for example, to control a computer hard drive or to sort scrap metal (Fig. 28-1). In Chapter 29, we discuss the magnetic field due to a current.

The other way to produce a magnetic field is by means of elementary particles such as electrons because these particles have an intrinsic magnetic field around them. That is, the magnetic field is a basic characteristic of each particle just as mass and electric charge (or lack of charge) are basic characteristics. As we discuss in Chapter 32, the magnetic fields of the electrons in certain materials add together to give a net magnetic field around the material. Such addition is the reason why a permanent magnet, the type used to hang refrigerator notes, has a permanent magnetic field. In other materials, the magnetic fields of the electrons cancel out, giving no net magnetic field surrounding the material. Such cancellation is the reason you do not have a permanent field around your body, which is good because otherwise you might be slammed up against a refrigerator door every time you passed one.

Our first job in this chapter is to define the magnetic field $\vec{B}$. We do so by using the experimental fact that when a charged particle moves through a magnetic field, a magnetic force $\vec{F}_B$ acts on the particle.

The Definition of $\vec{B}$

We determined the electric field $\vec{E}$ at a point by putting a test particle of charge $q$ at rest at that point and measuring the electric force $\vec{F}_E$ acting on the particle. We then defined $\vec{E}$ as

$$\vec{E} = \frac{\vec{F}_E}{q}. \tag{28-1}$$

If a magnetic monopole were available, we could define $\vec{B}$ in a similar way. Because such particles have not been found, we must define $\vec{B}$ in another way, in terms of the magnetic force $\vec{F}_B$ exerted on a moving electricly charged test particle.

Moving Charged Particle. In principle, we do this by firing a charged particle through the point at which $\vec{B}$ is to be defined, using various directions and speeds for the particle and determining the force $\vec{F}_B$ that acts on the particle at that point. After many such trials we would find that when the particle’s velocity
\( \vec{v} \) is along a particular axis through the point, force \( \vec{F}_B \) is zero. For all other directions of \( \vec{v} \), the magnitude of \( \vec{F}_B \) is always proportional to \( v \sin \phi \), where \( \phi \) is the angle between the zero-force axis and the direction of \( \vec{v} \). Furthermore, the direction of \( \vec{F}_B \) is always perpendicular to the direction of \( \vec{v} \). (These results suggest that a cross product is involved.)

**The Field.** We can then define a **magnetic field** \( \vec{B} \) to be a vector quantity that is directed along the zero-force axis. We can next measure the magnitude of \( \vec{F}_B \) when \( \vec{v} \) is directed perpendicular to that axis and then define the magnitude of \( \vec{B} \) in terms of that force magnitude:

\[
B = \frac{F_B}{|q|v},
\]

where \( q \) is the charge of the particle.

We can summarize all these results with the following vector equation:

\[
\vec{F}_B = q\vec{v} \times \vec{B}; \tag{28-2}
\]

that is, the force \( \vec{F}_B \) on the particle is equal to the charge \( q \) times the cross product of its velocity \( \vec{v} \) and the field \( \vec{B} \) (all measured in the same reference frame). Using Eq. 3-24 for the cross product, we can write the magnitude of \( \vec{F}_B \) as

\[
F_B = |q|vB \sin \phi, \tag{28-3}
\]

where \( \phi \) is the angle between the directions of velocity \( \vec{v} \) and magnetic field \( \vec{B} \).

**Finding the Magnetic Force on a Particle**

Equation 28-3 tells us that the magnitude of the force \( \vec{F}_B \) acting on a particle in a magnetic field is proportional to the charge \( q \) and speed \( v \) of the particle. Thus, the force is equal to zero if the charge is zero or if the particle is stationary. Equation 28-3 also tells us that the magnitude of the force is zero if \( \vec{v} \) and \( \vec{B} \) are either parallel (\( \phi = 0^\circ \)) or antiparallel (\( \phi = 180^\circ \)), and the force is at its maximum when \( \vec{v} \) and \( \vec{B} \) are perpendicular to each other.

**Directions.** Equation 28-2 tells us all this plus the direction of \( \vec{F}_B \). From Module 3-3, we know that the cross product \( \vec{v} \times \vec{B} \) in Eq. 28-2 is a vector that is perpendicular to the two vectors \( \vec{v} \) and \( \vec{B} \). The right-hand rule (Figs. 28-2a through c) tells us that the thumb of the right hand points in the direction of \( \vec{v} \times \vec{B} \) when the fingers sweep \( \vec{v} \) into \( \vec{B} \). If \( q \) is positive, then (by Eq. 28-2) the force \( \vec{F}_B \) has the same sign as \( \vec{v} \times \vec{B} \) and thus must be in the same direction; that is, for positive \( q \), \( \vec{F}_B \) is directed along the thumb (Fig. 28-2d). If \( q \) is negative, then
the force $\vec{F}_B$ and cross product $\vec{v} \times \vec{B}$ have opposite signs and thus must be in opposite directions. For negative $q$, $\vec{F}_B$ is directed opposite the thumb (Fig. 28-2e).

Heads up: Neglect of this effect of negative $q$ is a very common error on exams. Regardless of the sign of the charge, however, $\vec{F}_B$ never has a component parallel to $\vec{v}$. This means that $\vec{F}_B$ cannot change the particle’s speed $v$ (and thus it cannot change the particle’s kinetic energy). The force can change only the direction of $\vec{v}$ (and thus the direction of travel); only in this sense can $\vec{F}_B$ accelerate the particle.

To develop a feeling for Eq. 28-2, consider Fig. 28-3, which shows some tracks left by charged particles moving rapidly through a bubble chamber. The chamber, which is filled with liquid hydrogen, is immersed in a strong uniform magnetic field that is directed out of the plane of the figure. An incoming gamma ray particle—which leaves no track because it is uncharged—transforms into an electron (spiral track marked $e^-$) and a positron (track marked $e^+$) while it knocks an electron out of a hydrogen atom (long track marked $e^-$). Check with Eq. 28-2 and Fig. 28-2 that the three tracks made by these two negative particles and one positive particle curve in the proper directions.

**Unit.** The SI unit for $\vec{B}$ that follows from Eqs. 28-2 and 28-3 is the newton per coulomb-meter per second. For convenience, this is called the *tesla* (T):

$$1 \text{ tesla} = 1 \ T = 1 \frac{\text{newton}}{(\text{coulomb})(\text{meter/second})}.$$  

Recalling that a coulomb per second is an ampere, we have

$$1 \ T = 1 \frac{\text{newton}}{(\text{coulomb/second})(\text{meter})} = 1 \frac{\text{N}}{\text{A} \cdot \text{m}}. \quad (28-4)$$

An earlier (non-SI) unit for $\vec{B}$, still in common use, is the *gauss* (G), and

$$1 \text{ tesla} = 10^4 \text{ gauss}. \quad (28-5)$$

Table 28-1 lists the magnetic fields that occur in a few situations. Note that Earth’s magnetic field near the planet’s surface is about $10^{-4} \ T$ (= 100 $\mu$T or 1 G).

**Checkpoint 1**

The figure shows three situations in which a charged particle with velocity $\vec{v}$ travels through a uniform magnetic field $\vec{B}$. In each situation, what is the direction of the magnetic force $\vec{F}_B$ on the particle?

**Magnetic Field Lines**

We can represent magnetic fields with field lines, as we did for electric fields. Similar rules apply: (1) the direction of the tangent to a magnetic field line at any point gives the direction of $\vec{B}$ at that point, and (2) the spacing of the lines represents the magnitude of $\vec{B}$—the magnetic field is stronger where the lines are closer together, and conversely.
Figure 28-4a shows how the magnetic field near a bar magnet (a permanent magnet in the shape of a bar) can be represented by magnetic field lines. The lines all pass through the magnet, and they all form closed loops (even those that are not shown closed in the figure). The external magnetic effects of a bar magnet are strongest near its ends, where the field lines are most closely spaced. Thus, the magnetic field of the bar magnet in Fig. 28-4b collects the iron filings mainly near the two ends of the magnet.

**Two Poles.** The (closed) field lines enter one end of a magnet and exit the other end. The end of a magnet from which the field lines emerge is called the north pole of the magnet; the other end, where field lines enter the magnet, is called the south pole. Because a magnet has two poles, it is said to be a magnetic dipole. The magnets we use to fix notes on refrigerators are short bar magnets. Figure 28-5 shows two other common shapes for magnets: a horseshoe magnet and a magnet that has been bent around into the shape of a C so that the pole faces are facing each other. (The magnetic field between the pole faces can then be approximately uniform.) Regardless of the shape of the magnets, if we place two of them near each other we find:

Opposite magnetic poles attract each other, and like magnetic poles repel each other.

When you hold two magnets near each other with your hands, this attraction or repulsion seems almost magical because there is no contact between the two to visibly justify the pulling or pushing. As we did with the electrostatic force between two charged particles, we explain this noncontact force in terms of a field that you cannot see, here the magnetic field.

Earth has a magnetic field that is produced in its core by still unknown mechanisms. On Earth’s surface, we can detect this magnetic field with a compass, which is essentially a slender bar magnet on a low-friction pivot. This bar magnet, or this needle, turns because its north-pole end is attracted toward the Arctic region of Earth. Thus, the south pole of Earth’s magnetic field must be located toward the Arctic. Logically, we then should call the pole there a south pole. However, because we call that direction north, we are trapped into the statement that Earth has a geomagnetic north pole in that direction.

With more careful measurement we would find that in the Northern Hemisphere, the magnetic field lines of Earth generally point down into Earth and toward the Arctic. In the Southern Hemisphere, they generally point up out of Earth and away from the Antarctic—that is, away from Earth’s geomagnetic south pole.

Figure 28-5 (a) A horseshoe magnet and (b) a C-shaped magnet. (Only some of the external field lines are shown.)
Sample Problem 28.01  Magnetic force on a moving charged particle

A uniform magnetic field \( \vec{B} \), with magnitude 1.2 mT, is directed vertically upward throughout the volume of a laboratory chamber. A proton with kinetic energy 5.3 MeV enters the chamber, moving horizontally from south to north. What magnetic deflecting force acts on the proton as it enters the chamber? The proton mass is \( 1.67 \times 10^{-27} \) kg. (Neglect Earth’s magnetic field.)

**KEY IDEAS**

Because the proton is charged and moving through a magnetic field, a magnetic force \( \vec{F}_B \) can act on it. Because the initial direction of the proton’s velocity is not along a magnetic field line, \( \vec{F}_B \) is not simply zero.

**Magnitude:** To find the magnitude of \( \vec{F}_B \), we can use Eq. 28-3 \( \vec{F}_B = |q|vB \sin \phi \) provided we first find the proton’s speed \( v \).

We can find \( v \) from the given kinetic energy because

\[
K = \frac{1}{2}mv^2.
\]

Solving for \( v \), we obtain

\[
v = \sqrt{\frac{2K}{m}} = \sqrt{\frac{(2)(5.3 \text{ MeV})(1.60 \times 10^{-19} \text{ J/MeV})}{1.67 \times 10^{-27} \text{ kg}}} = 3.2 \times 10^7 \text{ m/s}.
\]

Equation 28-3 then yields

\[
F_B = |q|vB \sin \phi
= (1.60 \times 10^{-19} \text{ C})(3.2 \times 10^7 \text{ m/s})
\times (1.2 \times 10^{-3} \text{ T})(\sin 90^\circ)
= 6.1 \times 10^{-15} \text{ N}.
\]

This may seem like a small force, but it acts on a particle of small mass, producing a large acceleration; namely,

\[
a = \frac{F_B}{m} = \frac{6.1 \times 10^{-15} \text{ N}}{1.67 \times 10^{-27} \text{ kg}} = 3.7 \times 10^{12} \text{ m/s}^2.
\]

**Direction:** To find the direction of \( \vec{F}_B \), we use the fact that \( \vec{F}_B \) has the direction of the cross product \( q\vec{v} \times \vec{B} \). Because the charge \( q \) is positive, \( \vec{F}_B \) must have the same direction as \( \vec{v} \times \vec{B} \), which can be determined with the right-hand rule for cross products (as in Fig. 28-2d). We know that \( \vec{v} \) is directed horizontally from south to north and \( \vec{B} \) is directed vertically up. The right-hand rule shows us that the deflecting force \( \vec{F}_B \) must be directed horizontally from west to east, as Fig. 28-6 shows. (The array of dots in the figure represents a magnetic field directed out of the plane of the figure. An array of Xs would have represented a magnetic field directed into that plane.)

If the charge of the particle were negative, the magnetic deflecting force would be directed in the opposite direction—that is, horizontally from east to west. This is predicted automatically by Eq. 28-2 if we substitute a negative value for \( q \).

**Figure 28-6** An overhead view of a proton moving from south to north with velocity \( \vec{v} \) in a chamber. A magnetic field is directed vertically upward in the chamber, as represented by the array of dots (which resemble the tips of arrows). The proton is deflected toward the east.

Additional examples, video, and practice available at WileyPLUS

**28-2 CROSSED FIELDS: DISCOVERY OF THE ELECTRON**

**Learning Objectives**

After reading this module, you should be able to . . .

28.12 Describe the experiment of J. J. Thomson.
28.13 For a charged particle moving through a magnetic field and an electric field, determine the net force on the particle in both magnitude-angle notation and unit-vector notation.
28.14 In situations where the magnetic force and electric force on a particle are in opposite directions, determine the speeds at which the forces cancel, the magnetic force dominates, and the electric force dominates.

**Key Ideas**

- If a charged particle moves through a region containing both an electric field and a magnetic field, it can be affected by both an electric force and a magnetic force.
- If the fields are perpendicular to each other, they are said to be crossed fields.
- If the forces are in opposite directions, a particular speed will result in no deflection of the particle.
Crossed Fields: Discovery of the Electron

Both an electric field $\mathbf{E}$ and a magnetic field $\mathbf{B}$ can produce a force on a charged particle. When the two fields are perpendicular to each other, they are said to be crossed fields. Here we shall examine what happens to charged particles—namely, electrons—as they move through crossed fields. We use as our example the experiment that led to the discovery of the electron in 1897 by J. J. Thomson at Cambridge University.

Two Forces. Figure 28-7 shows a modern, simplified version of Thomson's experimental apparatus—a cathode ray tube (which is like the picture tube in an old-type television set). Charged particles (which we now know as electrons) are emitted by a hot filament at the rear of the evacuated tube and are accelerated by an applied potential difference $V$. After they pass through a slit in screen C, they form a narrow beam. They then pass through a region of crossed $\mathbf{E}$ and $\mathbf{B}$ fields, headed toward a fluorescent screen S, where they produce a spot of light (on a television screen the spot is part of the picture). The forces on the charged particles in the crossed-fields region can deflect them from the center of the screen. By controlling the magnitudes and directions of the fields, Thomson could thus control where the spot of light appeared on the screen. Recall that the force on a negatively charged particle due to an electric field is directed opposite the field. Thus, for the arrangement of Fig. 28-7, electrons are forced up the page by electric field and down the page by magnetic field; that is, the forces are in opposition. Thomson’s procedure was equivalent to the following series of steps.

1. Set $E = 0$ and $B = 0$ and note the position of the spot on screen S due to the undeflected beam.
2. Turn on $\mathbf{E}$ and measure the resulting beam deflection.
3. Maintaining $\mathbf{E}$, now turn on $\mathbf{B}$ and adjust its value until the beam returns to the undeflected position. (With the forces in opposition, they can be made to cancel.)

We discussed the deflection of a charged particle moving through an electric field $\mathbf{E}$ between two plates (step 2 here) in Sample Problem 22.04. We found that the deflection of the particle at the far end of the plates is

$$y = \frac{|q|EL^2}{2mv^2}.$$  \hspace{1cm} (28-6)

where $v$ is the particle’s speed, $m$ its mass, and $q$ its charge, and $L$ is the length of the plates. We can apply this same equation to the beam of electrons in Fig. 28-7; if need be, we can calculate the deflection by measuring the deflection of the beam on screen S and then working back to calculate the deflection $y$ at the end of the plates. (Because the direction of the deflection is set by the sign of the particle’s charge, Thomson was able to show that the particles that were lighting up his screen were negatively charged.)

Figure 28-7 A modern version of J. J. Thomson’s apparatus for measuring the ratio of mass to charge for the electron. An electric field $\mathbf{E}$ is established by connecting a battery across the deflecting-plate terminals. The magnetic field $\mathbf{B}$ is set up by means of a current in a system of coils (not shown). The magnetic field shown is into the plane of the figure, as represented by the array of Xs (which resemble the feathered ends of arrows).
When a uniform magnetic field $B$ is applied to a conducting strip carrying current $i$, with the field perpendicular to the direction of the current, a Hall-effect potential difference $V$ is set up across the strip.

The electric force on the charge carriers is then balanced by the magnetic force on them.

The number density $n$ of the charge carriers can then be determined from

$$n = \frac{Bi}{Vle},$$

where $l$ is the thickness of the strip (parallel to $B$).

When a conductor moves through a uniform magnetic field $B$ at speed $v$, the Hall-effect potential difference $V$ across it is

$$V = vBd,$$

where $d$ is the width perpendicular to both velocity $v$ and field $B$.

---

**Checkpoint 2**

The figure shows four directions for the velocity vector $\vec{v}$ of a positively charged particle moving through a uniform electric field $E$ (directed out of the page and represented with an encircled dot) and a uniform magnetic field $B$. (a) Rank directions 1, 2, and 3 according to the magnitude of the net force on the particle, greatest first. (b) Of all four directions, which might result in a net force of zero?
Crossed Fields: The Hall Effect

As we just discussed, a beam of electrons in a vacuum can be deflected by a magnetic field. Can the drifting conduction electrons in a copper wire also be deflected by a magnetic field? In 1879, Edwin H. Hall, then a 24-year-old graduate student at the Johns Hopkins University, showed that they can. This Hall effect allows us to find out whether the charge carriers in a conductor are positively or negatively charged. Beyond that, we can measure the number of such carriers per unit volume of the conductor.

Figure 28-8a shows a copper strip of width \( d \), carrying a current \( i \) whose conventional direction is from the top of the figure to the bottom. The charge carriers are electrons and, as we know, they drift (with drift speed \( v_d \)) in the opposite direction, from bottom to top. At the instant shown in Fig. 28-8a, an external magnetic field \( \mathbf{B} \), pointing into the plane of the figure, has just been turned on. From Eq. 28-2 we see that a magnetic deflecting force \( \mathbf{F} \) will act on each drifting electron, pushing it toward the right edge of the strip.

As time goes on, electrons move to the right, mostly piling up on the right edge of the strip, leaving uncompensated positive charges in fixed positions at the left edge. The separation of positive charges on the left edge and negative charges on the right edge produces an electric field \( \mathbf{E} \) within the strip, pointing from left to right in Fig. 28-8b. This field exerts an electric force \( \mathbf{F} \) on each electron, tending to push it to the left. Thus, this electric force on the electrons, which opposes the magnetic force on them, begins to build up.

**Equilibrium.** An equilibrium quickly develops in which the electric force on each electron has increased enough to match the magnetic force. When this happens, as Fig. 28-8b shows, the force due to \( \mathbf{B} \) and the force due to \( \mathbf{E} \) are in balance. The drifting electrons then move along the strip toward the top of the page at velocity \( v_d \) with no further collection of electrons on the right edge of the strip and thus no further increase in the electric field \( \mathbf{E} \).

A Hall potential difference \( V \) is associated with the electric field across strip width \( d \). From Eq. 24-21, the magnitude of that potential difference is

\[
V = Ed. \quad (28-9)
\]

By connecting a voltmeter across the width, we can measure the potential difference between the two edges of the strip. Moreover, the voltmeter can tell us which edge is at higher potential. For the situation of Fig. 28-8b, we would find that the left edge is at higher potential, which is consistent with our assumption that the charge carriers are negatively charged.

For a moment, let us make the opposite assumption, that the charge carriers in current \( i \) are positively charged (Fig. 28-8c). Convince yourself that as these charge carriers move from top to bottom in the strip, they are pushed to the right edge by \( F \) and thus that the right edge is at higher potential. Because that last statement is contradicted by our voltmeter reading, the charge carriers must be negatively charged.

**Number Density.** Now for the quantitative part. When the electric and magnetic forces are in balance (Fig. 28-8b), Eqs. 28-1 and 28-3 give us

\[
eE = ev_d B. \quad (28-10)
\]

From Eq. 26-7, the drift speed \( v_d \) is

\[
v_d = J / ne = i / neA, \quad (28-11)
\]

in which \( J (= i/A) \) is the current density in the strip, \( A \) is the cross-sectional area of the strip, and \( n \) is the number density of charge carriers (number per unit volume).

In Eq. 28-10, substituting for \( E \) with Eq. 28-9 and substituting for \( v_d \) with Eq. 28-11, we obtain

\[
n = \frac{Bi}{Vle}, \quad (28-12)
\]
in which \( l (= A/d) \) is the thickness of the strip. With this equation we can find \( n \) from measurable quantities.

**Drift Speed.** It is also possible to use the Hall effect to measure directly the drift speed \( v_d \) of the charge carriers, which you may recall is of the order of centimeters per hour. In this clever experiment, the metal strip is moved mechanically through the magnetic field in a direction opposite that of the drift velocity of the charge carriers. The speed of the moving strip is then adjusted until the Hall potential difference vanishes. At this condition, with no Hall effect, the velocity of the charge carriers *with respect to the laboratory frame* must be zero, so the velocity of the strip must be equal in magnitude but opposite the direction of the velocity of the negative charge carriers.

**Moving Conductor.** When a conductor begins to move at speed \( v \) through a magnetic field, its conduction electrons do also. They are then like the moving conduction electrons in the current in Figs. 28-8a and b, and an electric field \( \vec{E} \) and potential difference \( V \) are quickly set up. As with the current, equilibrium of the electric and magnetic forces is established, but we now write that condition in terms of the conductor’s speed \( v \) instead of the drift speed \( v_d \) in a current as we did in Eq. 28-10:

\[
eE = evB.
\]

Substituting for \( E \) with Eq. 28-9, we find that the potential difference is

\[
V = vBd. \tag{28-13}
\]

Such a motion-caused circuit potential difference can be of serious concern in some situations, such as when a conductor in an orbiting satellite moves through Earth’s magnetic field. However, if a conducting line (said to be an *electrodynam ic tether*) dangles from the satellite, the potential produced along the line might be used to maneuver the satellite.

---

**Sample Problem 28.02  Potential difference set up across a moving conductor**

Figure 28-9a shows a solid metal cube, of edge length \( d = 1.5 \) cm, moving in the positive \( y \) direction at a constant velocity \( \vec{v} \) of magnitude 4.0 m/s. The cube moves through a uniform magnetic field \( \vec{B} \) of magnitude 0.050 T in the positive \( z \) direction.

(a) Which cube face is at a lower electric potential and which is at a higher electric potential because of the motion through the field?

**KEY IDEA**

Because the cube is moving through a magnetic field \( \vec{B} \), a magnetic force \( \vec{F}_B \) acts on its charged particles, including its conduction electrons.

**Reasoning:** When the cube first begins to move through the magnetic field, its electrons do also. Because each electron has charge \( q \) and is moving through a magnetic field with velocity \( \vec{v} \), the magnetic force \( \vec{F}_B \) acting on the electron is given by Eq. 28-2. Because \( q \) is negative, the direction of \( \vec{F}_B \) is opposite the cross product \( \vec{v} \times \vec{B} \), which is in the positive direction of the \( x \) axis (Fig. 28-9b). Thus, \( \vec{F}_B \) acts in the negative direction of the \( x \) axis, toward the left face of the cube (Fig. 28-9c).

Most of the electrons are fixed in place in the atoms of the cube. However, because the cube is a metal, it contains conduction electrons that are free to move. Some of those conduction electrons are deflected by \( \vec{F}_B \) to the left cube face, making that face negatively charged and leaving the right face positively charged (Fig. 28-9d). This charge separation produces an electric field \( \vec{E} \) directed from the positively charged right face to the negatively charged left face (Fig. 28-9e). Thus, the left face is at a lower electric potential, and the right face is at a higher electric potential.

(b) What is the potential difference between the faces of higher and lower electric potential?

**KEY IDEAS**

1. The electric field \( \vec{E} \) created by the charge separation produces an electric force \( \vec{F}_E = q\vec{E} \) on each electron
**CROSSED FIELDS: THE HALL EFFECT**

This is the cross-product result.

This is the magnetic force on an electron.

Electrons are forced to the left face, leaving the right face positive.

This is the resulting electric field.

The weak electric field creates a weak electric force.

More migration creates a greater electric field.

The forces now balance. No more electrons move to the left face.

Figure 28-9  
(a) A solid metal cube moves at constant velocity through a uniform magnetic field.  
(b)–(d) In these front views, the magnetic force acting on an electron forces the electron to the left face, making that face negative and leaving the opposite face positive.  
(e)–(f) The resulting weak electric field creates a weak electric force on the next electron, but it too is forced to the left face.  
(g) The electric field is stronger and (h) the electric force matches the magnetic force.

2. When the cube had just begun to move through the magnetic field and the charge separation had just begun, the magnitude of $\vec{E}$ began to increase from zero. Thus, the magnitude of $\vec{F}_E$ also began to increase from zero and was initially smaller than the magnitude of $\vec{F}_B$. During this early stage, the net force on any electron was dominated by $\vec{F}_B$, which continuously moved additional electrons to the left cube face, increasing the charge separation between the left and right cube faces (Fig. 28-9g).

3. However, as the charge separation increased, eventually magnitude $\vec{F}_E$ became equal to magnitude $\vec{F}_B$ (Fig. 28-9h). Because the forces were in opposite directions, the net force on any electron was then zero, and no additional electrons were moved to the left cube face. Thus, the magnitude of $\vec{F}_E$ could not increase further, and the electrons were then in equilibrium.

**Calculations:** We seek the potential difference $V$ between the left and right cube faces after equilibrium was reached (which occurred quickly). We can obtain $V$ with Eq. 28-9 ($V = Ed$) provided we first find the magnitude $E$ of the electric field at equilibrium. We can do so with the equation for the balance of forces ($F_E = F_B$).

For $F_E$, we substitute $|q|E$, and then for $F_B$, we substitute $|q|vB \sin \phi$ from Eq. 28-3. From Fig. 28-9d, we see that the angle $\phi$ between velocity vector $\vec{v}$ and magnetic field vector $\vec{B}$ is $90^\circ$; thus $\sin \phi = 1$ and $F_E = F_B$ yields

$$|q|E = |q|vB \sin 90^\circ = |q|vB.$$  

This gives us $E = vB$; so $V = Ed$ becomes

$$V = vBd.$$  

Substituting known values tells us that the potential difference between the left and right cube faces is

$$V = (4.0 \text{ m/s})(0.050 \text{ T})(0.015 \text{ m}) = 0.0030 \text{ V} = 3.0 \text{ mV}. \quad \text{(Answer)}$$
A Circulating Charged Particle

Learning Objectives

After reading this module, you should be able to . . .

28.20 For a charged particle moving through a uniform magnetic field, identify under what conditions it will travel in a straight line, in a circular path, and in a helical path.

28.21 For a charged particle in uniform circular motion due to a magnetic force, start with Newton’s second law and derive an expression for the orbital radius \( r \) in terms of the field magnitude \( B \) and the particle’s mass \( m \), charge magnitude \( q \), and speed \( v \).

28.22 For a charged particle moving along a circular path in a magnetic field, calculate and relate speed, centripetal force, centripetal acceleration, radius, period, frequency, and angular frequency, and identify which of the quantities do not depend on speed.

28.23 For a positive particle and a negative particle moving along a circular path in a magnetic field, calculate and relate speed, centripetal force, centripetal acceleration, radius, period, frequency, and angular frequency, and identify which of the quantities do not depend on speed.

28.24 For a charged particle moving in a helical path in a magnetic field, sketch the path and indicate the magnetic field vector, the velocity vector, the result of the cross product of the velocity and field vectors, and the magnetic force vector.

28.25 For a charged particle moving in a helical path in a magnetic field, sketch the path and indicate the magnetic field, the pitch, the radius of curvature, the velocity component parallel to the field, and the velocity component perpendicular to the field.

28.26 For helical motion in a magnetic field, identify pitch \( p \) and relate it to one of the velocity components.

Key Ideas

- A charged particle with mass \( m \) and charge magnitude \( |q| \) moving with velocity \( \vec{v} \) perpendicular to a uniform magnetic field \( \vec{B} \) will travel in a circle.
- Applying Newton’s second law to the circular motion yields

\[
|q|vB = \frac{mv^2}{r},
\]

from which we find the radius \( r \) of the circle to be

\[
r = \frac{mv}{|q|B}.
\]

- The frequency of revolution \( f \), the angular frequency \( \omega \), and the period of the motion \( T \) are given by

\[
f = \frac{\omega}{2\pi} = \frac{1}{T} = \frac{|q|B}{2\pi m},
\]

- If the velocity of the particle has a component parallel to the magnetic field, the particle moves in a helical path about field vector \( \vec{B} \).

A Circulating Charged Particle

If a particle moves in a circle at constant speed, we can be sure that the net force acting on the particle is constant in magnitude and points toward the center of the circle, always perpendicular to the particle’s velocity. Think of a stone tied to a string and whirled in a circle on a smooth horizontal surface, or of a satellite moving in a circular orbit around Earth. In the first case, the tension in the string provides the necessary force and centripetal acceleration. In the second case, Earth’s gravitational attraction provides the force and acceleration.

Figure 28-10 shows another example: A beam of electrons is projected into a chamber by an electron gun G. The electrons enter in the plane of the page with speed \( v \) and then move in a region of uniform magnetic field \( \vec{B} \) directed out of that plane. As a result, a magnetic force \( \vec{F}_B = q\vec{v} \times \vec{B} \) continuously deflects the electrons, and because \( \vec{v} \) and \( \vec{B} \) are always perpendicular to each other, this deflection causes the electrons to follow a circular path. The path is visible in the photo because atoms of gas in the chamber emit light when some of the circulating electrons collide with them.

We would like to determine the parameters that characterize the circular motion of these electrons, or of any particle of charge magnitude \( |q| \) and mass \( m \) moving perpendicular to a uniform magnetic field \( \vec{B} \) at speed \( v \). From Eq. 28-3, the force acting on the particle has a magnitude of \( |q|vB \). From Newton’s second law \( (\vec{F} = ma) \) applied to uniform circular motion (Eq. 6-18),

\[
F = m \frac{v^2}{r}, \tag{28-14}
\]
we have

\[ |q| v B = \frac{mv^2}{r} \]  

Solving for \( r \), we find the radius of the circular path as

\[ r = \frac{mv}{|q|B} \]  

The period \( T \) (the time for one full revolution) is equal to the circumference divided by the speed:

\[ T = \frac{2\pi r}{v} = \frac{2\pi}{v} \frac{mv}{|q|B} = \frac{2\pi m}{|q|B} \]  

The frequency \( f \) (the number of revolutions per unit time) is

\[ f = \frac{1}{T} = \frac{|q|B}{2\pi m} \]  

The angular frequency \( \omega \) of the motion is then

\[ \omega = 2\pi f = \frac{|q|B}{m} \]  

The quantities \( T \), \( f \), and \( \omega \) do not depend on the speed of the particle (provided the speed is much less than the speed of light). Fast particles move in large circles and slow ones in small circles, but all particles with the same charge-to-mass ratio \( |q|/m \) take the same time \( T \) (the period) to complete one round trip. Using Eq. 28-2, you can show that if you are looking in the direction of \( \vec{B} \), the direction of rotation for a positive particle is always counterclockwise, and the direction for a negative particle is always clockwise.
The velocity component perpendicular to the field causes circling, which is stretched upward by the parallel component.

Figure 28-11  (a) A charged particle moves in a uniform magnetic field \( \vec{B} \), the particle’s velocity \( \vec{v} \) making an angle \( \phi \) with the field direction. (b) The particle follows a helical path of radius \( r \) and pitch \( p \). (c) A charged particle spiraling in a nonuniform magnetic field. (The particle can become trapped in this magnetic bottle, spiraling back and forth between the strong field regions at either end.) Note that the magnetic force vectors at the left and right sides have a component pointing toward the center of the figure.

**Helical Paths**

If the velocity of a charged particle has a component parallel to the (uniform) magnetic field, the particle will move in a helical path about the direction of the field vector. Figure 28-11a, for example, shows the velocity vector \( \vec{v} \) of such a particle resolved into two components, one parallel to \( \vec{B} \) and one perpendicular to it:

\[
\begin{align*}
v_y &= v \cos \phi & v_z &= v \sin \phi.
\end{align*}
\]  

The parallel component determines the pitch \( p \) of the helix — that is, the distance between adjacent turns (Fig. 28-11b). The perpendicular component determines the radius of the helix and is the quantity to be substituted for \( v \) in Eq. 28-16.

Figure 28-11c shows a charged particle spiraling in a nonuniform magnetic field. The more closely spaced field lines at the left and right sides indicate that the magnetic field is stronger there. When the field at an end is strong enough, the particle “reflects” from that end.

**Checkpoint 3**

The figure here shows the circular paths of two particles that travel at the same speed in a uniform magnetic field \( \vec{B} \), which is directed into the page. One particle is a proton; the other is an electron (which is less massive). (a) Which particle follows the smaller circle, and (b) does that particle travel clockwise or counterclockwise?

---

**Sample Problem 28.03  Helical motion of a charged particle in a magnetic field**

An electron with a kinetic energy of 22.5 eV moves into a region of uniform magnetic field \( \vec{B} \) of magnitude \( 4.55 \times 10^{-4} \) T. The angle between the directions of \( \vec{B} \) and the electron’s velocity \( \vec{v} \) is 65.5°. What is the pitch of the helical path taken by the electron?

**Calculations:** Using Eqs. 28-20 and 28-17, we find

\[
p = v_y T = (v \cos \phi) \frac{2\pi m}{|q|B}.
\]  

Calculating the electron’s speed \( v \) from its kinetic energy, we find that \( v = 2.81 \times 10^6 \) m/s, and so Eq. 28-21 gives us

\[
p = (2.81 \times 10^6 \) m/s)(cos 65.5°)
\times \frac{2\pi(9.11 \times 10^{-3} \) kg)}{(1.60 \times 10^{-19} \) C)(4.55 \times 10^{-4} \) T}

= 9.16 cm.  

(Answer)

---

**KEY IDEAS**

1. The pitch \( p \) is the distance the electron travels parallel to the magnetic field \( \vec{B} \) during one period \( T \) of circulation.
2. The period \( T \) is given by Eq. 28-17 for any nonzero angle between \( \vec{v} \) and \( \vec{B} \).

---

**WileyPLUS** Additional examples, video, and practice available at WileyPLUS
Sample Problem 28.04  Uniform circular motion of a charged particle in a magnetic field

Figure 28-12 shows the essentials of a mass spectrometer, which can be used to measure the mass of an ion; an ion of mass \( m \) (to be measured) and charge \( q \) is produced in source \( S \). The initially stationary ion is accelerated by the electric field due to a potential difference \( V \). The ion leaves \( S \) and enters a separator chamber in which a uniform magnetic field \( B \) is perpendicular to the path of the ion. A wide detector lines the bottom wall of the chamber, and the \( B \) causes the ion to move in a semicircle and thus strike the detector. Suppose that \( B = 80.000 \text{ mT} \), \( V = 1000.0 \text{ V} \), and ions of charge \( q = +1.6022 \times 10^{-19} \text{ C} \) strike the detector at a point that lies at \( x = 1.6254 \text{ m} \). What is the mass \( m \) of the individual ions, in atomic mass units (Eq. 1-7: 1 u = \( 1.6605 \times 10^{-27} \text{ kg} \))?  

**KEY IDEAS**

(1) Because the (uniform) magnetic field causes the (charged) ion to follow a circular path, we can relate the ion’s mass \( m \) to the path’s radius \( r \) with Eq. 28-16 \( (r = mv/|q|B) \). From Fig. 28-12 we see that \( r = x/2 \) (the radius is half the diameter). From the problem statement, we know the magnitude \( B \) of the magnetic field. However, we lack the ion’s speed \( v \) in the magnetic field after the ion has been accelerated due to the potential difference \( V \). (2) To relate \( v \) and \( V \), we use the fact that mechanical energy \( (E_{\text{mech}} = K + U) \) is conserved during the acceleration.

**Finding speed:** When the ion emerges from the source, its kinetic energy is approximately zero. At the end of the acceleration, its kinetic energy is \( \frac{1}{2}mv^2 \). Also, during the acceleration, the positive ion moves through a change in potential of \(-V\). Thus, because the ion has positive charge \( q \), its potential energy changes by \(-qV\). If we now write the conservation of mechanical energy as

\[
\Delta K + \Delta U = 0,
\]

we get

\[
\frac{1}{2}mv^2 - qV = 0
\]

or

\[
v = \sqrt{\frac{2qV}{m}}.
\]

**Finding mass:** Substituting this value for \( v \) into Eq. 28-16 gives us

\[
r = \frac{mv}{qB} = \frac{m}{qB} \sqrt{\frac{2qV}{m}} = \frac{1}{B} \sqrt{\frac{2mV}{q}}.
\]

Thus,

\[
x = 2r = \frac{2}{B} \sqrt{\frac{2mV}{q}}.
\]

Solving this for \( m \) and substituting the given data yield

\[
m = \frac{B^2qx^2}{8V}
\]

\[
= \frac{(0.080000 \text{ T})^2 (1.6022 \times 10^{-19} \text{ C})(1.6254 \text{ m})^2}{8(1000.0 \text{ V})}
\]

\[
= 3.3863 \times 10^{-25} \text{ kg} = 203.93 \text{ u}.
\]

(Answer)

**28-5 CYCLOTRONS AND SYNCHROTRONS**

**Learning Objectives**

After reading this module, you should be able to . . .

28.27 Describe how a cyclotron works, and in a sketch indicate a particle’s path and the regions where the kinetic energy is increased.

28.28 Identify the resonance condition.

28.29 For a cyclotron, apply the relationship between the particle’s mass and charge, the magnetic field, and the frequency of circling.

28.30 Distinguish between a cyclotron and a synchrotron.

**Key Ideas**

- In a cyclotron, charged particles are accelerated by electric forces as they circle in a magnetic field.

- A synchrotron is needed for particles accelerated to nearly the speed of light.
Cyclotrons and Synchrotrons

Beams of high-energy particles, such as high-energy electrons and protons, have been enormously useful in probing atoms and nuclei to reveal the fundamental structure of matter. Such beams were instrumental in the discovery that atomic nuclei consist of protons and neutrons and in the discovery that protons and neutrons consist of quarks and gluons. Because electrons and protons are charged, they can be accelerated to the required high energy if they move through large potential differences. The required acceleration distance is reasonable for electrons (low mass) but unreasonable for protons (greater mass).

A clever solution to this problem is first to let protons and other massive particles move through a modest potential difference (so that they gain a modest amount of energy) and then use a magnetic field to cause them to circle back and move through a modest potential difference again. If this procedure is repeated thousands of times, the particles end up with a very large energy.

Here we discuss two accelerators that employ a magnetic field to repeatedly bring particles back to an accelerating region, where they gain more and more energy until they finally emerge as a high-energy beam.

The Cyclotron

Figure 28-13 is a top view of the region of a cyclotron in which the particles (protons, say) circulate. The two hollow D-shaped objects (each open on its straight edge) are made of sheet copper. These dees, as they are called, are part of an electrical oscillator that alternates the electric potential difference across the gap between the dees. The electrical signs of the dees are alternated so that the electric field in the gap alternates in direction, first toward one dee and then toward the other dee, back and forth. The dees are immersed in a large magnetic field directed out of the plane of the page. The magnitude $B$ of this field is set via a control on the electromagnet producing the field.

Suppose that a proton, injected by source $S$ at the center of the cyclotron in Fig. 28-13, initially moves toward a negatively charged dee. It will accelerate toward this dee and enter it. Once inside, it is shielded from electric fields by the copper walls of the dee; that is, the electric field does not enter the dee. The magnetic field, however, is not screened by the (nonmagnetic) copper dee, so the proton moves in a circular path whose radius, which depends on its speed, is given by Eq. 28-16 ($r = \frac{mv}{q}\frac{1}{2}B$).

Let us assume that at the instant the proton emerges into the center gap from the first dee, the potential difference between the dees is reversed. Thus, the proton again faces a negatively charged dee and is again accelerated. This process continues, the circulating proton always being in step with the oscillations of the dee potential, until the proton has spiraled out to the edge of the dee system. There a deflector plate sends it out through a portal.

**Frequency.** The key to the operation of the cyclotron is that the frequency $f$ at which the proton circulates in the magnetic field (and that does not depend on its speed) must be equal to the fixed frequency $f_{\text{osc}}$ of the electrical oscillator, or

$$f = f_{\text{osc}} \quad \text{(resonance condition).} \quad (28-23)$$

This *resonance condition* says that, if the energy of the circulating proton is to increase, energy must be fed to it at a frequency $f_{\text{osc}}$ that is equal to the natural frequency $f$ at which the proton circulates in the magnetic field.

Combining Eqs. 28-18 ($f = \frac{|q|B/2\pi m}$) and 28-23 allows us to write the resonance condition as

$$|q|B = 2\pi mf_{\text{osc}}. \quad (28-24)$$

The oscillator (we assume) is designed to work at a single fixed frequency $f_{\text{osc}}$. We
then “tune” the cyclotron by varying $B$ until Eq. 28-24 is satisfied, and then many protons circulate through the magnetic field, to emerge as a beam.

**The Proton Synchrotron**

At proton energies above 50 MeV, the conventional cyclotron begins to fail because one of the assumptions of its design — that the frequency of revolution of a charged particle circulating in a magnetic field is independent of the particle’s speed — is true only for speeds that are much less than the speed of light. At greater proton speeds (above about 10% of the speed of light), we must treat the problem relativistically. According to relativity theory, as the speed of a circulating proton approaches speeds (above about 10% of the speed of light), we must treat the problem relativistically. At greater proton speeds (above about 10% of the speed of light), we must treat the problem relativistically. Thus, the proton gets out of step with the cyclotron’s oscillator — whose frequency remains fixed at $f_{osc}$ — and eventually the energy of the still circulating proton stops increasing.

There is another problem. For a 500 GeV proton in a magnetic field of 1.5 T, the path radius is 1.1 km. The corresponding magnet for a conventional cyclotron of the proper size would be impossibly expensive, the area of its pole faces being about $4 \times 10^6$ m$^2$.

The proton synchrotron is designed to meet these two difficulties. The magnetic field $B$ and the oscillator frequency $f_{osc}$, instead of having fixed values as in the conventional cyclotron, are made to vary with time during the accelerating cycle. When this is done properly, (1) the frequency of the circulating protons remains in step with the oscillator at all times, and (2) the protons follow a circular — not a spiral — path. Thus, the magnet need extend only along that circular path, not over some $4 \times 10^6$ m$^2$. The circular path, however, still must be large if high energies are to be achieved.

**Sample Problem 28.05  Accelerating a charged particle in a cyclotron**

Suppose a cyclotron is operated at an oscillator frequency of 12 MHz and has a dee radius $R = 53$ cm.

(a) What is the magnitude of the magnetic field needed for deuterons to be accelerated in the cyclotron? The deuteron mass is $m = 3.34 \times 10^{-27}$ kg (twice the proton mass).

**KEY IDEA**

For a given oscillator frequency $f_{osc}$, the magnetic field magnitude $B$ required to accelerate any particle in a cyclotron depends on the ratio $m/|q|$ of mass to charge for the particle, according to Eq. 28-24 ($|q|B = 2\pi mf_{osc}$).

**Calculation:** For deuterons and the oscillator frequency $f_{osc} = 12$ MHz, we find

$$B = \frac{2\pi mf_{osc}}{|q|} = \frac{(2\pi)(3.34 \times 10^{-27} \text{kg})(12 \times 10^6 \text{s}^{-1})}{1.60 \times 10^{-19} \text{C}} = 1.57 \text{ T} \approx 1.6 \text{ T}.$$  

(Answer)

Note that, to accelerate protons, $B$ would have to be reduced by a factor of 2, provided the oscillator frequency remained fixed at 12 MHz.

(b) What is the resulting kinetic energy of the deuterons?

**KEY IDEAS**

1. The kinetic energy ($\frac{1}{2}mv^2$) of a deuteron exiting the cyclotron is equal to the kinetic energy it had just before exiting, when it was traveling in a circular path with a radius approximately equal to the radius $R$ of the cyclotron dees. (Answer)

2. We can find the speed $v$ of the deuteron in that circular path with Eq. 28-16 ($r = mv/|q|B$).

**Calculations:** Solving that equation for $v$, substituting $R$ for $r$, and then substituting known data, we find

$$v = \frac{R|q|B}{m} = \frac{(0.53 \text{ m})(1.60 \times 10^{-19} \text{C})(1.57 \text{ T})}{3.34 \times 10^{-27} \text{kg}} = 3.99 \times 10^7 \text{ m/s}.$$  

This speed corresponds to a kinetic energy of

$$K = \frac{1}{2}mv^2 = \frac{1}{2}(3.34 \times 10^{-27} \text{kg})(3.99 \times 10^7 \text{m/s})^2 = 2.7 \times 10^{-12} \text{ J},$$  

(Answer) or about 17 MeV.
MAGNETIC FORCE ON A CURRENT-CARRYING WIRE

Learning Objectives

After reading this module, you should be able to . . .

28.31 For the situation where a current is perpendicular to a magnetic field, sketch the current, the direction of the magnetic field, and the direction of the magnetic force on the current (or wire carrying the current).

28.32 For a current in a magnetic field, apply the relationship between the magnetic force magnitude \( F_B \), the current \( i \), the length of the wire \( L \), and the angle \( \phi \) between the length vector \( \vec{L} \) and the field vector \( \vec{B} \).

28.33 Apply the right-hand rule for cross products to find the direction of the magnetic force on a current in a magnetic field.

28.34 For a current in a magnetic field, calculate the magnetic force with a cross product of the length vector and the field vector, in magnitude-angle and unit-vector notations.

28.35 Describe the procedure for calculating the force on a current-carrying wire in a magnetic field if the wire is not straight or if the field is not uniform.

Key Ideas

- A straight wire carrying a current \( i \) in a uniform magnetic field experiences a sideways force
  \[ \vec{F}_B = i \vec{L} \times \vec{B}. \]
- The force acting on a current element \( i \, d\vec{L} \) in a magnetic field is
  \[ d\vec{F}_B = i \, d\vec{L} \times \vec{B}. \]
- The direction of the length vector \( \vec{L} \) or \( d\vec{L} \) is that of the current \( i \).

Magnetic Force on a Current-Carrying Wire

We have already seen (in connection with the Hall effect) that a magnetic field exerts a sideways force on electrons moving in a wire. This force must then be transmitted to the wire itself, because the conduction electrons cannot escape sideways out of the wire.

In Fig. 28-14a, a vertical wire, carrying no current and fixed in place at both ends, extends through the gap between the vertical pole faces of a magnet. The magnetic field between the faces is directed outward from the page. In Fig. 28-14b, a current is sent upward through the wire; the wire deflects to the right. In Fig. 28-14c, we reverse the direction of the current and the wire deflects to the left.

Figure 28-15 shows what happens inside the wire of Fig. 28-14b. We see one of the conduction electrons, drifting downward with an assumed drift speed \( v_d \). Equation 28-3, in which we must put \( \phi = 90^\circ \), tells us that a force \( \vec{F}_B \) of magnitude \( ev_dB \) must act on each such electron. From Eq. 28-2 we see that this force must be directed to the right. We expect then that the wire as a whole will experience a force to the right, in agreement with Fig. 28-14b.

If, in Fig. 28-15, we were to reverse either the direction of the magnetic field or the direction of the current, the force on the wire would reverse, being directed now to the left. Note too that it does not matter whether we consider negative charges.
drifting downward in the wire (the actual case) or positive charges drifting upward. The direction of the deflecting force on the wire is the same. We are safe then in dealing with a current of positive charge, as we usually do in dealing with circuits.

**Find the Force.** Consider a length $L$ of the wire in Fig. 28-15. All the conduction electrons in this section of wire will drift past plane $xx$ in Fig. 28-15 in a time $t = L/v_d$. Thus, in that time a charge given by

$$q = it = i \frac{L}{v_d}$$

will pass through that plane. Substituting this into Eq. 28-3 yields

$$F_B = q v_d B \sin \phi = \frac{iL}{v_d} v_d B \sin 90^\circ$$

or

$$F_B = iL B.$$  \hspace{1cm} (28-25)

Note that this equation gives the magnetic force that acts on a length $L$ of straight wire carrying a current $i$ and immersed in a uniform magnetic field $\vec{B}$ that is perpendicular to the wire.

If the magnetic field is *not* perpendicular to the wire, as in Fig. 28-16, the magnetic force is given by a generalization of Eq. 28-25:

$$\vec{F}_B = i\vec{L} \times \vec{B} \hspace{0.5cm} \text{(force on a current).} \hspace{1cm} (28-26)$$

Here $\vec{L}$ is a *length vector* that has magnitude $L$ and is directed along the wire segment in the direction of the (conventional) current. The force magnitude $F_B$ is

$$F_B = iL B \sin \phi,$$  \hspace{1cm} (28-27)

where $\phi$ is the angle between the directions of $\vec{L}$ and $\vec{B}$. The direction of $\vec{F}_B$ is that of the cross product $\vec{L} \times \vec{B}$ because we take current $i$ to be a positive quantity. Equation 28-26 tells us that $\vec{F}_B$ is always perpendicular to the plane defined by vectors $\vec{L}$ and $\vec{B}$, as indicated in Fig. 28-16.

Equation 28-26 is equivalent to Eq. 28-2 in that either can be taken as the defining equation for $\vec{F}_B$. In practice, we define $\vec{F}_B$ from Eq. 28-26 because it is much easier to measure the magnetic force acting on a wire than that on a single moving charge.

**Crooked Wire.** If a wire is not straight or the field is not uniform, we can imagine the wire broken up into small straight segments and apply Eq. 28-26 to each segment. The force on the wire as a whole is then the vector sum of all the forces on the segments that make it up. In the differential limit, we can write

$$d\vec{F}_B = i d\vec{L} \times \vec{B},$$  \hspace{1cm} (28-28)

and we can find the resultant force on any given arrangement of currents by integrating Eq. 28-28 over that arrangement.

In using Eq. 28-28, bear in mind that there is no such thing as an isolated current-carrying wire segment of length $dL$. There must always be a way to introduce the current into the segment at one end and take it out at the other end.

**Checkpoint 4**

The figure shows a current $i$ through a wire in a uniform magnetic field $\vec{B}$, as well as the magnetic force $\vec{F}_B$ acting on the wire. The field is oriented so that the force is maximum. In what direction is the field?
KEY IDEAS

(1) Because the wire carries a current, a magnetic force \( \vec{F}_B \) can act on the wire if we place it in a magnetic field \( \vec{B} \). To balance the downward gravitational force \( \vec{F}_g \) on the wire, we want \( \vec{F}_B \) to be directed upward (Fig. 28-17). (2) The direction of \( \vec{F}_g \) is related to the directions of \( \vec{B} \) and the wire’s length vector \( \vec{L} \) by Eq. 28-26 \( \vec{F}_g = \vec{iL} \times \vec{B} \).

Calculations: Because \( \vec{L} \) is directed horizontally (and the current is taken to be positive), Eq. 28-26 and the right-hand rule for cross products tell us that \( \vec{B} \) must be horizontal and rightward (in Fig. 28-17) to give the required upward \( \vec{F}_B \).

The magnitude of \( \vec{F}_B \) is \( F_B = iLB \sin \phi \) (Eq. 28-27). Because we want \( \vec{F}_B \) to balance \( \vec{F}_g \), we want

\[
iLB \sin \phi = mg,
\]

where \( mg \) is the magnitude of \( \vec{F}_g \) and \( m \) is the mass of the wire. We also want the minimal field magnitude \( B \) for \( \vec{F}_B \) to balance \( \vec{F}_g \). Thus, we need to maximize \( \sin \phi \) in Eq. 28-29. To do so, we set \( \phi = 90^\circ \), thereby arranging for \( \vec{B} \) to be perpendicular to the wire. We then have \( \sin \phi = 1 \), so Eq. 28-29 yields

\[
B = \frac{mg}{iL} \sin \phi = \frac{(mL)g}{i}.
\]

We write the result this way because we know \( m/L \), the linear density of the wire. Substituting known data then gives us

\[
B = \frac{(46.6 \times 10^{-3} \text{ kg/m})(9.8 \text{ m/s}^2)}{28 \text{ A}} = 1.6 \times 10^{-2} \text{ T}.
\]

This is about 160 times the strength of Earth’s magnetic field.
Figure 28-18 shows a simple motor, consisting of a single current-carrying loop immersed in a magnetic field \( \vec{B} \). The two magnetic forces \( \vec{F} \) and \(-\vec{F}\) produce a torque on the loop, tending to rotate it about its central axis. Although many essential details have been omitted, the figure does suggest how the action of a magnetic field on a current loop produces rotary motion. Let us analyze that action.

Figure 28-19a shows a rectangular loop of sides \( a \) and \( b \), carrying current \( i \) through uniform magnetic field \( \vec{B} \). We place the loop in the field so that its long sides, labeled 1 and 3, are perpendicular to the field direction (which is into the page), but its short sides, labeled 2 and 4, are not. Wires to lead the current into and out of the loop are needed but, for simplicity, are not shown.

To define the orientation of the loop in the magnetic field, we use a normal vector \( \vec{n} \) that is perpendicular to the plane of the loop. Figure 28-19b shows a right-hand rule for finding the direction of \( \vec{n} \). Point or curl the fingers of your right hand in the direction of the current at any point on the loop. Your extended thumb then points in the direction of the normal vector \( \vec{n} \).

In Fig. 28-19c, the normal vector of the loop is shown at an arbitrary angle \( \theta \) to the direction of the magnetic field \( \vec{B} \). We wish to find the net force and net torque acting on the loop in this orientation.

**Net Torque.** The net force on the loop is the vector sum of the forces acting on its four sides. For side 2 the vector \( \vec{L} \) in Eq. 28-26 points in the direction of the current and has magnitude \( b \). The angle between \( \vec{L} \) and \( \vec{B} \) for side 2 (see Fig. 28-19c) is \( 90^\circ - \theta \). Thus, the magnitude of the force acting on this side is

\[
F_2 = ibB \sin(90^\circ - \theta) = ibB \cos \theta. \tag{28-31}
\]

You can show that the force \( \vec{F}_4 \) acting on side 4 has the same magnitude as \( \vec{F}_2 \) but the opposite direction. Thus, \( \vec{F}_2 \) and \( \vec{F}_4 \) cancel out exactly. Their net force is zero and, because their common line of action is through the center of the loop, their net torque is also zero.

The situation is different for sides 1 and 3. For them, \( \vec{L} \) is perpendicular to \( \vec{B} \), so the forces \( \vec{F}_1 \) and \( \vec{F}_3 \) have the common magnitude \( iaB \). Because these two forces have opposite directions, they do not tend to move the loop up or down. However, as Fig. 28-19c shows, these two forces do not share the same line of action; so they do not produce a net torque. The torque tends to rotate the loop so as to align its normal vector \( \vec{n} \) with the direction of the magnetic field \( \vec{B} \). That torque has moment arm \( (b/2) \sin \theta \) about the central axis of the loop. The magnitude \( \tau' \) of the torque due to forces \( \vec{F}_1 \) and \( \vec{F}_3 \) is then (see Fig. 28-19c)

\[
\tau' = \left( iab \frac{b}{2} \sin \theta \right) + \left( iab \frac{b}{2} \sin \theta \right) = iabB \sin \theta. \tag{28-32}
\]

**Coil.** Suppose we replace the single loop of current with a coil of \( N \) loops, or turns. Further, suppose that the turns are wound tightly enough that they can be...
approximated as all having the same dimensions and lying in a plane. Then the
turns form a flat coil, and a torque \( \tau' \) with the magnitude given in Eq. 28-32 acts
on each of them. The total torque on the coil then has magnitude

\[ \tau = N \tau' = Niab \sin \theta = (NiA)B \sin \theta, \quad (28-33) \]

in which \( A \) \((= ab)\) is the area enclosed by the coil. The quantities in parentheses
\((NiA)\) are grouped together because they are all properties of the coil: its number
of turns, its area, and the current it carries. Equation 28-33 holds for all flat coils,
no matter what their shape, provided the magnetic field is uniform. For example,
for the common circular coil, with radius \( r \), we have

\[ \tau = (Ni \pi r^2)B \sin \theta. \quad (28-34) \]

**Normal Vector.** Instead of focusing on the motion of the coil, it is simpler to
keep track of the vector \( \vec{n} \), which is normal to the plane of the coil. Equation 28-33
tells us that a current-carrying flat coil placed in a magnetic field will tend to
rotate so that \( \vec{n} \) has the same direction as the field. In a motor, the current in
the coil is reversed as \( \vec{n} \) begins to line up with the field direction, so that a torque
continues to rotate the coil. This automatic reversal of the current is done via
a commutator that electrically connects the rotating coil with the stationary con-
tacts on the wires that supply the current from some source.

---

**28-8 THE MAGNETIC DIPOLE MOMENT**

**Learning Objectives**

*After reading this module, you should be able to . . .*

- **28.38** Identify that a current-carrying coil is a magnetic dipole with a magnetic dipole moment \( \vec{\mu} \) that has the direction of the normal vector \( \vec{n} \), as given by a right-hand rule.
- **28.39** For a current-carrying coil, apply the relationship between the magnitude \( \mu \) of the magnetic dipole moment, the number of turns \( N \), the area \( A \) of each turn, and the current \( i \).
- **28.40** On a sketch of a current-carrying coil, draw the direction of the current, and then use a right-hand rule to determine the direction of the magnetic dipole moment vector \( \vec{\mu} \).
- **28.41** For a magnetic dipole in an external magnetic field, apply the relationship between the torque magnitude \( \tau \), the dipole moment magnitude \( \mu \), the magnetic field magnitude \( B \), and the angle \( \theta \) between the dipole moment vector \( \vec{\mu} \) and the magnetic field vector \( \vec{B} \).
- **28.42** Identify the convention of assigning a plus or minus sign to a torque according to the direction of rotation.
- **28.43** Calculate the torque on a magnetic dipole by evaluating a cross product of the dipole moment vector \( \vec{\mu} \) and the external magnetic field vector \( \vec{B} \), in magnitude-angle notation and unit-vector notation.
- **28.44** For a magnetic dipole in an external magnetic field, identify the dipole orientations at which the torque magnitude is minimum and maximum.
- **28.45** For a magnetic dipole in an external magnetic field, apply the relationship between the orientation energy \( U \), the dipole moment magnitude \( \mu \), the external magnetic field magnitude \( B \), and the angle \( \theta \) between the dipole moment vector \( \vec{\mu} \) and the magnetic field vector \( \vec{B} \).
- **28.46** Calculate the orientation energy \( U \) by taking a dot product of the dipole moment vector \( \vec{\mu} \) and the external magnetic field vector \( \vec{B} \), in magnitude-angle and unit-vector notations.
- **28.47** Identify the orientations of a magnetic dipole in an external magnetic field that give the minimum and maximum orientation energies.
- **28.48** For a magnetic dipole in a magnetic field, relate the orientation energy \( U \) to the work \( W_a \) done by an external torque as the dipole rotates in the magnetic field.

**Key Ideas**

- A coil (of area \( A \) and \( N \) turns, carrying current \( i \)) in a uniform magnetic field \( \vec{B} \) will experience a torque \( \vec{\tau} \) given by

\[ \vec{\tau} = \vec{\mu} \times \vec{B}. \]

Here \( \vec{\mu} \) is the magnetic dipole moment of the coil, with magnitude \( \mu = NiA \) and direction given by the right-hand rule.

- The orientation energy of a magnetic dipole in a magnetic field is

\[ U(\theta) = -\vec{\mu} \cdot \vec{B}. \]

- If an external agent rotates a magnetic dipole from an initial orientation \( \theta_i \) to some other orientation \( \theta_f \) and the dipole is stationary both initially and finally, the work \( W_a \) done on the dipole by the agent is

\[ W_a = \Delta U = U_f - U_i. \]
The Magnetic Dipole Moment

As we have just discussed, a torque acts to rotate a current-carrying coil placed in a magnetic field. In that sense, the coil behaves like a bar magnet placed in the magnetic field. Thus, like a bar magnet, a current-carrying coil is said to be a *magnetic dipole*. Moreover, to account for the torque on the coil due to the magnetic field, we assign a *magnetic dipole moment* \( \vec{\mu} \) to the coil. The direction of \( \vec{\mu} \) is that of the normal vector \( \vec{n} \) to the plane of the coil and thus is given by the same right-hand rule shown in Fig. 28-19. That is, grasp the coil with the fingers of your right hand in the direction of current \( i \); the outstretched thumb of that hand gives the direction of \( \vec{\mu} \). The magnitude of \( \vec{\mu} \) is given by

\[
\mu = NiA \quad \text{(magnetic moment)}, \quad (28-35)
\]

in which \( N \) is the number of turns in the coil, \( i \) is the current through the coil, and \( A \) is the area enclosed by each turn of the coil. From this equation, with \( i \) in amperes and \( A \) in square meters, we see that the unit of \( \vec{\mu} \) is the ampere–square meter (A m\(^2\)).

**Torque.** Using \( \vec{\mu} \), we can rewrite Eq. 28-33 for the torque on the coil due to a magnetic field as

\[
\tau = \mu B \sin \theta, \quad (28-36)
\]

in which \( \theta \) is the angle between the vectors \( \vec{\mu} \) and \( \vec{B} \).

We can generalize this to the vector relation

\[
\vec{\tau} = \vec{\mu} \times \vec{B}, \quad (28-37)
\]

which reminds us very much of the corresponding equation for the torque exerted by an electric field on an electric dipole—namely, Eq. 22-34:

\[
\vec{\tau} = \vec{p} \times \vec{E}.
\]

In each case the torque due to the field—either magnetic or electric—is equal to the vector product of the corresponding dipole moment and the field vector.

**Energy.** A magnetic dipole in an external magnetic field has an energy that depends on the dipole’s orientation in the field. For electric dipoles we have shown (Eq. 22-38) that

\[
U(\theta) = -\vec{\mu} \cdot \vec{E}.
\]

In strict analogy, we can write for the magnetic case

\[
U(\theta) = -\vec{\mu} \cdot \vec{B}. \quad (28-38)
\]

In each case the energy due to the field is equal to the negative of the scalar product of the corresponding dipole moment and the field vector.

A magnetic dipole has its lowest energy \((=-\mu B \cos 0 = -\mu B)\) when its dipole moment \( \vec{\mu} \) is lined up with the magnetic field (Fig. 28-20). It has its highest energy \((=-\mu B \cos 180^\circ = +\mu B)\) when \( \vec{\mu} \) is directed opposite the field. From Eq. 28-38, with \( U \) in joules and \( \vec{B} \) in teslas, we see that the unit of \( \vec{\mu} \) can be the joule per tesla (J/T) instead of the ampere–square meter as suggested by Eq. 28-35.

**Work.** If an applied torque (due to “an external agent”) rotates a magnetic dipole from an initial orientation \( \theta_i \) to another orientation \( \theta_f \), then work \( W_a \) is done on the dipole by the applied torque. *If the dipole is stationary* before and after the change in its orientation, then work \( W_a \) is

\[
W_a = U_f - U_i, \quad (28-39)
\]

where \( U_f \) and \( U_i \) are calculated with Eq. 28-38.
So far, we have identified only a current-carrying coil and a permanent magnet as a magnetic dipole. However, a rotating sphere of charge is also a magnetic dipole, as is Earth itself (approximately). Finally, most subatomic particles, including the electron, the proton, and the neutron, have magnetic dipole moments. As you will see in Chapter 32, all these quantities can be viewed as current loops. For comparison, some approximate magnetic dipole moments are shown in Table 28-2.

Language. Some instructors refer to $U$ in Eq. 28-38 as a potential energy and relate it to work done by the magnetic field when the orientation of the dipole changes. Here we shall avoid the debate and say that $U$ is an energy associated with the dipole orientation.

### Checkpoint 5

The figure shows four orientations, at angle $\theta$, of a magnetic dipole moment $\vec{\mu}$ in a magnetic field. Rank the orientations according to (a) the magnitude of the torque on the dipole and (b) the orientation energy of the dipole, greatest first.

#### Sample Problem 28.07 Rotating a magnetic dipole in a magnetic field

Figure 28-21 shows a circular coil with 250 turns, an area $A$ of $2.52 \times 10^{-4}$ m$^2$, and a current of 100 $\mu$A. The coil is at rest in a uniform magnetic field of magnitude $B = 0.85$ T, with its magnetic dipole moment $\vec{\mu}$ initially aligned with $\vec{B}$.

(a) In Fig. 28-21, what is the direction of the current in the coil?

**Right-hand rule:** Imagine cupping the coil with your right hand so that your right thumb is outstretched in the direction of $\vec{\mu}$. The direction in which your fingers curl around the coil is the direction of the current in the coil. Thus, in the wires on the near side of the coil—those we see in Fig. 28-21—the current is from top to bottom.

(b) How much work would the torque applied by an external agent have to do on the coil to rotate it 90° from its initial orientation, so that $\vec{\mu}$ is perpendicular to $\vec{B}$ and the coil is again at rest?

**KEY IDEA**

The work $W_a$ done by the applied torque would be equal to the change in the coil’s orientation energy due to its change in orientation.

**Calculations:** From Eq. 28-39 ($W_a = U_f - U_i$), we find

$$W_a = U(90°) - U(0°) = -\mu B \cos 90° - (-\mu B \cos 0°) = 0 + \mu B = \mu B.$$ 

Substituting for $\mu$ from Eq. 28-35 ($\mu = NiA$), we find that

$$W_a = (NiA)B = (250)(100 \times 10^{-6} A)(2.52 \times 10^{-4} m^2)(0.85 T) = 5.355 \times 10^{-6} J \approx 5.4 \mu J.$$ 

(Answer) Similarly, we can show that to change the orientation by another 90°, so that the dipole moment is opposite the field, another 5.4 $\mu J$ is required.
**Review & Summary**

**Magnetic Field** $\vec{B}$  
A magnetic field $\vec{B}$ is defined in terms of the force $\vec{F}_B$ acting on a test particle with charge $q$ moving through the field with velocity $\vec{v}$:

$$\vec{F}_B = q\vec{v} \times \vec{B}. \quad (28-2)$$

The SI unit for $\vec{B}$ is the **tesla** (T): $1 \, \text{T} = 1 \, \text{N} / (\text{A} \cdot \text{m}) = 10^4 \, \text{gauss}.$

**The Hall Effect**  
When a conducting strip carrying a current $i$ is placed in a uniform magnetic field $\vec{B}$, some charge carriers (with charge $e$) build up on one side of the conductor, creating a potential difference $V$ across the strip. The polarities of the sides indicate the sign of the charge carriers.

**A Charged Particle Circulating in a Magnetic Field**  
A charged particle with mass $m$ and charge magnitude $|q|$ moving with velocity $\vec{v}$ perpendicular to a uniform magnetic field $\vec{B}$ will travel in a circle. Applying Newton’s second law to the circular motion yields

$$|q|vB = \frac{mv^2}{r}, \quad (28-15)$$

from which we find the radius $r$ of the circle to be

$$r = \frac{mv}{|q|B}. \quad (28-16)$$

The frequency of revolution $f$, the angular frequency $\omega$, and the period of the motion $T$ are given by

$$f = \frac{\omega}{2\pi} = \frac{1}{T} = \frac{|q|B}{2\pi m} \quad (28-19, 28-18, 28-17)$$

**Questions**

1. Figure 28-22 shows three situations in which a positively charged particle moves at velocity $\vec{v}$ through a uniform magnetic field $\vec{B}$ and experiences a magnetic force $\vec{F}_B$. In each situation, determine whether the orientations of the vectors are physically reasonable.

   ![Figure 28-22](image)

2. Figure 28-23 shows a wire that carries current to the right through a uniform magnetic field. It also shows four choices for the direction of that field. (a) Rank the choices according to the magnitude of the electric potential difference that would be set up across the width of the wire, greatest first. (b) For which choice is the top side of the wire at higher potential than the bottom side of the wire?

3. Figure 28-24 shows a metallic, rectangular solid that is to move at a certain speed $v$ through the uniform magnetic field $\vec{B}$. The dimensions of the solid are multiples of $d$, as shown. You have six choices for the direction of the velocity: parallel to $x$, $y$, or $z$ in either the positive or negative direction. (a) Rank the six choices according to the potential difference set up across the solid, greatest first. (b) For which choice is the front face at lower potential?

4. Figure 28-25 shows the path of a particle through six regions of uniform magnetic field, where the path is either a half-circle or a quarter-circle. Upon leaving the last region, the particle travels between two charged, parallel plates and is deflected toward the plate of higher potential. What is the direction of the magnetic field in each of the six regions?

![Figure 28-24](image)

![Figure 28-25](image)
In Module 28-2, we discussed a charged particle moving through crossed fields with the forces \( \vec{F}_E \) and \( \vec{F}_B \) in opposition. We found that the particle moves in a straight line (that is, neither force dominates the motion) if its speed is given by Eq. 28-7 \( v = E/B \). Which of the two forces dominates if the speed of the particle is (a) \( v < E/B \) and (b) \( v > E/B \)?

Figure 28-26 shows crossed uniform electric and magnetic fields \( E \) and \( B \), and, at a certain instant, the velocity vectors of the 10 charged particles listed in Table 28-3. (The vectors are not drawn to scale.) The speeds given in the table are either less than or greater than \( E/B \) (see Question 5). Which particles will move out of the page toward you after the instant shown in Fig. 28-26?

Figure 28-26 Question 6.

Table 28-4 Question 10

Figure 28-29 Question 10.

Figure 28-27 shows the path of an electron that passes through two regions containing uniform magnetic fields of magnitudes \( B_1 \) and \( B_2 \). Its path in each region is a half-circle. (a) Which field is stronger? (b) What is the direction of each field? (c) Is the time spent by the electron in the \( B_1 \) region greater than, less than, or the same as the time spent in the \( B_2 \) region?

Figure 28-27 Question 7.

Figure 28-28 shows the path of an electron in a region of uniform magnetic field. The path consists of two straight sections, each between a pair of uniformly charged plates, and two half-circles. Which plate is at the higher electric potential in (a) the top pair of plates and (b) the bottom pair? (c) What is the direction of the magnetic field?

Figure 28-28 Question 8.

(a) In Checkpoint 5, if the dipole moment \( \mu \) is rotated from orientation 2 to orientation 1 by an external agent, is the work done on the dipole by the agent positive, negative, or zero? (b) Rank the work done on the dipole by the agent for these three rotations, greatest first: \( 2 \rightarrow 1, 2 \rightarrow 4, 2 \rightarrow 3 \).

Particle roundabout. Figure 28-29 shows 11 paths through a region of uniform magnetic field. One path is a straight line; the rest are half-circles. Table 28-4 gives the masses, charges, and speeds of 11 particles that take these paths through the field in the directions shown. Which path in the figure corresponds to which particle in the table? (The direction of the magnetic field can be determined by means of one of the paths, which is unique.)

Figure 28-29 Question 10.

Figure 28-30 gives snapshots for three situations in which a positively charged particle passes through a uniform magnetic field \( \vec{B} \) with speed \( v_o \), moves through a half-circle in time \( T_o \), and then leaves the field. (a) Is the charge positive or negative? (b) Is the final speed of the particle greater than, less than, or equal to \( v_o \)? (c) If the initial speed had been \( 0.5v_o \), would the time spent in field \( \vec{B} \) have been greater than, less than, or equal to \( T_o \)? (d) Would the path have been a half-circle, more than a half-circle, or less than a half-circle?

Figure 28-30 Question 11.

Figure 28-31 gives snapshots for three situations in which a positively charged particle passes through a uniform magnetic field \( \vec{B} \). The velocities \( \vec{v} \) of the particle differ in orientation in the three snapshots but not in magnitude. Rank the situations according to (a) the period, (b) the frequency, and (c) the pitch of the particle’s motion, greatest first.

Figure 28-31 Question 12.
Module 28-1 Magnetic Fields and the Definition of $\vec{B}$

1. A proton traveling at 23.0° with respect to the direction of a magnetic field of strength 2.60 T experiences a magnetic force of $6.50 \times 10^{-17}$ N. Calculate (a) the proton’s speed and (b) its kinetic energy in electron-volts.

2. A particle of mass 10 g and charge 80 $\mu$C moves through a uniform magnetic field, in a region where the free-fall acceleration is $-9.80$ m/s². The velocity of the particle is a constant $20i$ km/s, which is perpendicular to the magnetic field. What, then, is the magnetic field?

3. An electron that has an instantaneous velocity of $\vec{v} = (2.0 \times 10^6 \text{ m/s})\hat{i} + (3.0 \times 10^6 \text{ m/s})\hat{j}$ is moving through the uniform magnetic field $\vec{B} = (0.030 \text{ T})\hat{i} - (0.15 \text{ T})\hat{j}$. (a) Find the force on the electron due to the magnetic field. (b) Repeat your calculation for the proton having the same velocity.

4. An alpha particle travels at a velocity $\vec{v} = (550 \text{ m/s})\hat{i}$ through a uniform magnetic field $\vec{B}$ of magnitude 0.045 T. (An alpha particle has a charge of $+3.2 \times 10^{-19}$ C and a mass of $6.6 \times 10^{-27}$ kg.) The angle between $\vec{v}$ and $\vec{B}$ is 52°. What is the magnitude of (a) the force $\vec{F}_B$ acting on the particle due to the field and (b) the acceleration of the particle due to $\vec{F}_B$? (c) Does the speed of the particle increase, decrease, or remain the same?

5. An electron moves through a uniform magnetic field given by $\vec{B} = B_x\hat{i} + (3.0B_z)\hat{j}$. At a particular instant, the electron has velocity $\vec{v} = (2.0i + 4.0j)$ m/s and the magnetic force acting on it is $(6.4 \times 10^{-19})\text{ N}$. Find $B_z$.

6. A proton moves through a uniform magnetic field given by $\vec{B} = (10\hat{i} - 20\hat{j} + 30\hat{k})$ mT. At time $t_1$, the proton has a velocity given by $\vec{v} = v_x\hat{i} + v_y\hat{j} + (2.0 \text{ km/s})\hat{k}$ and the magnetic force on the proton is $\vec{F}_B = (4.0 \times 10^{-17})\text{ N}\hat{i} + (2.0 \times 10^{-17})\text{ N}\hat{j}$. At that instant, what are (a) $v_x$ and (b) $v_y$?

Module 28-2 Crossed Fields: Discovery of the Electron

7. An electron has an initial velocity of $(12.0\hat{i} + 15.0\hat{k})$ km/s and a constant acceleration of $(2.00 \times 10^{12} \text{ m/s}^2)\hat{i}$ in a region in which uniform electric and magnetic fields are present. If $\vec{E} = (400 \mu\text{T})\hat{i}$, find the electric field $\vec{E}$.

8. An electric field of 1.50 kV/m and a perpendicular magnetic field of 0.400 T act on a moving electron to produce no net force. What is the electron’s speed?

9. In Fig. 28-32, an electron accelerated from rest through potential difference $V_1 = 1.00 \text{ kV}$ enters the gap between two parallel plates having separation $d = 20.0 \text{ mm}$ and potential difference $V_2 = 100 \text{ V}$. The lower plate is at the lower potential. Neglect fringing and assume that the electron’s velocity vector is perpendicular to the electric field vector between the plates. In unit-vector notation, what uniform magnetic field allows the electron to travel in a straight line in the gap?

10. A proton travels through uniform magnetic and electric fields. The magnetic field is $\vec{B} = -2.50 \text{ mT}$. At one instant the velocity of the proton is $\vec{v} = (2000\text{ km/s})\hat{i}$. At that instant and in unit-vector notation, what is the net force acting on the proton if the electric field is (a) $(4.00 \text{ kV/m})\hat{i}$, (b) $-4.00 \text{ kV/m}$, and (c) $4.00 \text{ kV/m}$?

11. An ion source is producing $^6\text{Li}$ ions, which have charge $+e$ and mass $9.99 \times 10^{-27}$ kg. The ions are accelerated by a potential difference of 10 kV and pass horizontally into a region in which there is a uniform vertical magnetic field of magnitude $B = 1.2 \text{ T}$. Calculate the strength of the smallest electric field, to be set up over the same region, that will allow the $^6\text{Li}$ ions to pass through undeflected.

12. At time $t_1$, an electron is sent along the positive direction of an $x$ axis, through both an electric field $\vec{E}$ and a magnetic field $\vec{B}$, with $\vec{E}$ directed parallel to the $y$ axis. Figure 28-33 gives the $y$ component $F_{net,y}$ of the net force on the electron due to the two fields, as a function of the electron’s speed $v$ at time $t_1$. The scale of the velocity axis is set by $v = 100.0 \text{ m/s}$. The $x$ and $z$ components of the net force are zero at $t_1$. Assuming $\vec{B} = 0$, find (a) the magnitude $E$ and (b) $\vec{B}$ in unit-vector notation.

Module 28-3 Crossed Fields: The Hall Effect

13. A strip of copper 150 $\mu$m thick and 4.5 mm wide is placed in a uniform magnetic field $\vec{B}$ of magnitude 0.65 T, with $\vec{B}$ perpendicular to the strip. A current $i = 23 \text{ A}$ is then sent through the strip such that a Hall potential difference $V$ appears across the width of the strip. Calculate $V$. (The number of charge carriers per unit volume for copper is $8.47 \times 10^{28}$ electrons/m$^3$.)

14. A metal strip 6.50 cm long, 0.85 cm wide, and 0.76 mm thick moves with constant velocity $\vec{v}$ through a uniform magnetic field $B = 1.20 \text{ mT}$ directed perpendicular to the strip, as shown in Fig. 28-34. A potential difference of $3.90 \mu\text{V}$ is measured between points $x$ and $y$ across the strip. Calculate the speed $v$.

15. A conducting rectangular solid of dimensions $d_x = 5.00 \text{ m}$, $d_y = 3.00 \text{ m}$, and $d_z = 2.00 \text{ m}$ moves with a constant velocity $\vec{v} = (20.0 \text{ m/s})\hat{i}$ through a uniform magnetic field...
\( \vec{B} = (30.0 \text{ mT}) \hat{j} \) (Fig. 28-35). What are the resulting (a) electric field within the solid, in unit-vector notation, and (b) potential difference across the solid?

**16** Figure 28-35 shows a metallic block, with its faces parallel to coordinate axes. The block is in a uniform magnetic field of magnitude 0.020 T. One edge length of the block is 25 cm; the block is not drawn to scale. The block is moved at 3.0 m/s parallel to each axis, in turn, and the resulting potential difference \( V \) that appears across the block is measured. With the motion parallel to the \( y \) axis, \( V_y = 12 \text{ mV} \); with the motion parallel to the \( z \) axis, \( V_z = 18 \text{ mV} \); with the motion parallel to the \( x \) axis, \( V_x = 0 \). What are the block lengths (a) \( d_x \), (b) \( d_y \), and (c) \( d_z \)?

**Module 28-4 A Circulating Charged Particle**

**17** An alpha particle can be produced in certain radioactive decays of nuclei and consists of two protons and two neutrons. The particle has a charge of \( q = +2e \) and a mass of 4.00 u, where u is the atomic mass unit, with \( 1 \text{ u} = 1.661 \times 10^{-27} \text{ kg} \). Suppose an alpha particle travels in a circular path of radius 4.50 cm in a uniform magnetic field with \( B = 1.20 \text{ T} \). Calculate (a) its speed, (b) its period of revolution, (c) its kinetic energy, and (d) the potential difference through which it would have to be accelerated to achieve this energy.

**18** In Fig. 28-36, a particle moves along a circle in a region of uniform magnetic field of magnitude \( B = 4.00 \text{ mT} \). The particle is either a proton or an electron (you must decide which). It experiences a magnetic force of magnitude \( 3.20 \times 10^{-15} \text{ N} \). What are (a) the particle’s speed, (b) the radius of the circle, and (c) the period of the motion?

**19** A certain particle is sent into a uniform magnetic field, with the particle’s velocity vector perpendicular to the direction of the field. Figure 28-37 gives the period \( T \) of the particle’s motion versus the inverse of the field magnitude \( B \). The vertical axis scale is set by \( T_0 = 40.0 \text{ ns} \), and the horizontal axis scale is set by \( B_0^{-1} = 5.0 \text{ T}^{-1} \). What is the ratio \( m/q \) of the particle’s mass to the magnitude of its charge?

**20** An electron is accelerated from rest through potential difference \( V \) and then enters a region of uniform magnetic field, where it undergoes uniform circular motion. Figure 28-38 gives the radius \( r \) of that motion versus \( V^{1/2} \). The vertical axis scale is set by \( r_0 = 3.0 \text{ mm} \), and the horizontal axis scale is set by \( V_0^{1/2} = 40.0 \text{ V}^{1/2} \). What is the magnitude of the magnetic field?

**21** An electron of kinetic energy 1.20 keV circles in a plane perpendicular to a uniform magnetic field. The orbit radius is 25.0 cm. Find (a) the electron’s speed, (b) the magnetic field magnitude, (c) the circling frequency, and (d) the period of the motion.

**22** In a nuclear experiment a proton with kinetic energy 1.0 MeV moves in a circular path in a uniform magnetic field. What energy must (a) an alpha particle \( (q = +2e, m = 4.0 \text{ u}) \) and (b) a deuterion \( (q = +e, m = 2.0 \text{ u}) \) have if they are to circulate in the same circular path?

**23** What uniform magnetic field, applied perpendicular to a beam of electrons moving at \( 1.30 \times 10^6 \text{ m/s} \), is required to make the electrons travel in a circular arc of radius 0.350 m?

**24** An electron is accelerated from rest by a potential difference of 350 V. It then enters a uniform magnetic field of magnitude \( 200 \text{ mT} \) with its velocity perpendicular to the field. Calculate (a) the speed of the electron and (b) the radius of its path in the magnetic field.

**25** (a) Find the frequency of revolution of an electron with an energy of 100 eV in a uniform magnetic field of magnitude \( 350 \mu \text{T} \). (b) Calculate the radius of the path of this electron if its velocity is perpendicular to the magnetic field.

**26** In Fig. 28-39, a charged particle moves into a region of uniform magnetic field \( \vec{B} \), goes through half a circle, and then exits that region. The particle is either a proton or an electron (you must decide which). It spends 130 ns in the region. (a) What is the magnitude of \( B \)? (b) If the particle is sent back through the magnetic field (along the same initial path) but with 2.00 times its previous kinetic energy, how much time does it spend in the field during this trip?

**27** A mass spectrometer (Fig. 28-12) is used to separate uranium ions of mass \( 3.92 \times 10^{-25} \text{ kg} \) and charge \( 3.20 \times 10^{-19} \text{ C} \) from related species. The ions are accelerated through a potential difference of 100 kV and then pass into a uniform magnetic field, where they are bent in a path of radius 1.00 m. After traveling through 180° and passing through a slit of width 1.00 mm and height 1.00 cm, they are collected in a cup. (a) What is the magnitude of the (perpendicular) magnetic field in the separator? If the machine is used to separate out 100 mg of material per hour, calculate (b) the current of the desired ions in the machine and (c) the thermal energy produced in the cup in 1.00 h.

**28** A particle undergoes uniform circular motion of radius 26.1 \( \mu \text{m} \) in a uniform magnetic field. The magnetic force on the particle has a magnitude of \( 1.60 \times 10^{-17} \text{ N} \). What is the kinetic energy of the particle?

**29** An electron follows a helical path in a uniform magnetic field of magnitude 0.300 T. The pitch of the path is 6.00 \( \mu \text{m} \), and the
forming into an electron $e^-$.

- **•30** In Fig. 28-40, an electron with an initial kinetic energy of 4.0 keV enters region 1 at time $t = 0$. That region contains a uniform magnetic field directed into the page, with magnitude 0.010 T. The electron goes through a half-circle and then exits region 1, headed toward region 2 across a gap of 25.0 cm. There is an electric potential difference $\Delta V = 200$ V across the gap, with a polarity such that the electron’s speed increases uniformly as it traverses the gap. Region 2 contains a uniform magnetic field directed out of the page, with magnitude 0.020 T. The electron goes through a half-circle and then leaves region 2. At what time $t$ does it leave?

- **•31** A particular type of fundamental particle decays by transforming into an electron $e^-$ and a positron $e^+$. Suppose the decaying particle is at rest in a uniform magnetic field $B$ of magnitude 3.53 mT and the $e^-$ and $e^+$ move away from the decay point in paths lying in a plane perpendicular to $B$. How long after the decay do the $e^-$ and $e^+$ collide?

- **•32** A source injects an electron of speed $v = 1.5 \times 10^7$ m/s into a uniform magnetic field of magnitude $B = 1.0 \times 10^{-2}$ T. The velocity of the electron makes an angle $\theta = 10^\circ$ with the direction of the magnetic field. Find the distance $d$ from the point of injection at which the electron next crosses the field line that passes through the injection point.

- **•33 SSM WWW** A positron with kinetic energy 2.00 keV is projected into a uniform magnetic field $B$ of magnitude 0.100 T, with its velocity vector making an angle of 89.0° with $B$. Find (a) the period, (b) the pitch $p$, and (c) the radius $r$ of its helical path.

- **•34** An electron follows a helical path in a uniform magnetic field given by $B = (20i - 50j - 30k)$ mT. At time $t = 0$, the electron’s velocity is given by $v = (20i - 30j + 50k)$ m/s. (a) What is the angle $\phi$ between $v$ and $B$? The electron’s velocity changes with time. Do (b) its speed and (c) the angle $\phi$ change with time? (d) What is the radius of the helical path?

**Module 28-5 Cyclotrons and Synchrotrons**

- **•35** A proton circulates in a cyclotron, beginning approximately at rest at the center. Whenever it passes through the gap between dees, the electric potential difference between the dees is 200 V. (a) By how much does its kinetic energy increase with each passage through the gap? (b) What is its kinetic energy as it completes 100 passes through the gap? Let $r_{100}$ be the radius of the proton’s circular path as it completes those 100 passes and enters a dee, and let $r_{101}$ be its next radius, as it enters a dee the next time. (c) By what percentage does the radius increase when it changes from $r_{100}$ to $r_{101}$? That is, what is the percentage increase $\frac{r_{101} - r_{100}}{r_{100}} \times 100\%$?

- **•36** A cyclotron with dee radius 53.0 cm is operated at an oscillator frequency of 12.0 MHz to accelerate protons. (a) What magnitude $B$ of magnetic field is required to achieve resonance? (b) At that field magnitude, what is the kinetic energy of a proton emerging from the cyclotron? Suppose, instead, that $B = 1.57$ T. (c) What oscillator frequency is required to achieve resonance now? (d) At that frequency, what is the kinetic energy of an emerging proton?

- **•37** Estimate the total path length traveled by a deuteron in a cyclotron of radius 53 cm and operating frequency 12 MHz during the (entire) acceleration process. Assume that the accelerating potential between the dees is 80 kV.

- **•38** In a certain cyclotron a proton moves in a circle of radius 0.500 m. The magnitude of the magnetic field is 1.20 T. (a) What is the oscillator frequency? (b) What is the kinetic energy of the proton, in electron-volts?

**Module 28-6 Magnetic Force on a Current-Carrying Wire**

- **•39 SSM** A horizontal power line carries a current of 5000 A from south to north. Earth’s magnetic field (60.0 $\mu$T) is directed toward the north and inclined downward at 70.0° to the horizontal. Find the (a) magnitude and (b) direction (left or right) of the current required to remove the tension in the supporting leads.

- **•40** A wire 1.80 m long carries a current of 13.0 A and makes an angle of 35.0° with a uniform magnetic field of magnitude $B = 1.50$ T. Calculate the magnetic force on the wire.

- **•41 ILW** A 13.0 g wire of length $L = 62.0$ cm is suspended by a pair of flexible leads in a uniform magnetic field of magnitude 0.440 T (Fig. 28-41). What are the (a) magnitude and (b) direction (left or right) of the current required to remove the tension in the supporting leads?

- **•42** The bent wire shown in Fig. 28-42 lies in a uniform magnetic field. Each straight section is 2.0 m long and makes an angle of $\theta = 60^\circ$ with the $x$ axis, and the wire carries a current of 2.0 A. What is the net magnetic force on the wire in unit-vector notation if the magnetic field is given by (a) 4.0$i$ T and (b) 4.0$i$ T?

- **•43** A single-turn current loop, carrying a current of 4.00 A, is in the shape of a right triangle with sides 50.0, 120, and 130 cm. The loop is in a uniform magnetic field of magnitude 75.0 mT whose direction is parallel to the current in the 130 cm side of the loop. What is the magnitude of the magnetic force on (a) the 130 cm side, (b) the 50.0 cm side, and (c) the 120 cm side? (d) What is the magnitude of the net force on the loop?

- **•44** Figure 28-43 shows a wire ring of radius $r = 1.8$ cm that is perpendicular to the general direction of a radially symmetric, diverging magnetic field. The magnetic field at the ring is everywhere of the same magnitude $B = 3.4$ mT, and its direction at the ring everywhere makes an angle $\theta = 20^\circ$ with a normal to the plane of the ring. The twisted lead wires have no effect on the problem. Find the magnitude of the force the field exerts on the ring if the ring carries a current $i = 4.6$ mA.

- **•45** A wire 50.0 cm long carries a 0.500 A current in the positive direction of an $x$ axis through a magnetic field $B = (3.00 \text{ mT})\hat{j} + (10.0 \text{ mT})\hat{k}$. In unit-vector notation, what is the magnetic force on the wire?
In Fig. 28-44, a metal wire of mass \( m = 24.1 \text{ mg} \) can slide with negligible friction on two horizontal parallel rails separated by distance \( d = 2.56 \text{ cm} \). The track lies in a vertical uniform magnetic field of magnitude 56.3 mT. At time \( t = 0 \), device \( G \) is connected to the rails, producing a constant current \( i = 9.13 \text{ mA} \) in the wire and rails (even as the wire moves). At \( t = 61.1 \text{ ms} \), what are the wire’s (a) speed and (b) direction of motion (left or right)?

![Figure 28-44 Problem 46.](image)

In Fig. 28-47, a rectangular loop carrying current lies in the plane of a uniform magnetic field of magnitude 0.040 T. The loop consists of a single turn of flexible conducting wire that is wrapped around a flexible mount such that the dimensions of the rectangle can be changed. (The total length of the wire is not changed.) As edge length \( x \) is varied from approximately zero to its maximum value of approximately 4.0 cm, the magnitude \( \tau \) of the torque on the loop changes. The maximum value of \( \tau \) is \( 4.80 \times 10^{-5} \text{ N} \cdot \text{m} \). What is the current in the loop?

![Figure 28-47 Problem 52.](image)

Prove that the relation \( \tau = NiAB \sin \theta \) holds not only for the rectangular loop of Fig. 28-19 but also for a closed loop of any shape. (Hint: Replace the loop of arbitrary shape with an assembly of adjacent long, thin, approximately rectangular loops that are nearly equivalent to the loop of arbitrary shape as far as the distribution of current is concerned.)

**Module 28-8 The Magnetic Dipole Moment**

A magnetic dipole with a dipole moment of magnitude 0.020 J/T is released from rest in a uniform magnetic field of magnitude 52 mT. The rotation of the dipole due to the magnetic force on it is unimpeded. When the dipole rotates through the orientation where its dipole moment is aligned with the magnetic field, its kinetic energy is 0.80 mJ. (a) What is the initial angle between the dipole moment and the magnetic field? (b) What is the angle when the dipole is next (momentarily) at rest?

Two concentric, circular wire loops, of radii \( r_1 = 20.0 \text{ cm} \) and \( r_2 = 30.0 \text{ cm} \), are located in an \( xy \) plane; each carries a clockwise current of 7.00 A (Fig. 28-48). (a) Find the magnitude of the net magnetic dipole moment of the system. (b) Repeat for reversed current in the inner loop.

A circular wire loop of radius 15.0 cm carries a current of 2.60 A. It is placed so that the normal to its plane makes an angle of 41.0° with a uniform magnetic field of magnitude 12.0 T. (a) Calculate the magnitude of the magnetic dipole moment of the loop. (b) What is the magnitude of the torque acting on the loop?

A circular coil of 160 turns has a radius of 1.90 cm. (a) Calculate the current that results in a magnetic dipole moment of magnitude 2.30 A \cdot \text{m}^2. \) (b) Find the maximum magnitude of the torque that the coil, carrying this current, can experience in a uniform 35.0 mT magnetic field.

The magnetic dipole moment of Earth has magnitude \( 8.00 \times 10^{22} \text{ J/T} \). Assume that this is produced by charges flowing in Earth’s molten outer core. If the radius of their circular path is 3500 km, calculate the current they produce.

A current loop, carrying a current of 5.0 A, is in the shape of a right triangle with sides 30, 40, and 50 cm. The loop is in a uniform magnetic field of magnitude 80 mT whose direction is parallel to the current in the 50 cm side of the loop. Find the magnitude of (a) the magnetic dipole moment of the loop and (b) the torque on the loop.

**Module 28-7 Torque on a Current Loop**

A 1.0 kg copper rod rests on two horizontal rails 1.0 m apart and carries a current of 50 A from one rail to the other. The coefficient of static friction between rod and rails is 0.60. What are the (a) magnitude and (b) angle (relative to the vertical) of the smallest magnetic field that puts the rod on the verge of sliding?

A long, rigid conductor, lying along an \( x \) axis, carries a current of 5.0 A in the negative \( x \) direction. A magnetic field \( B \) is present, given by \( B = 3.0i + 8.0x^2j \), with \( x \) in meters and \( B \) in milliteslas. Find, in unit-vector notation, the force on the 2.0 m segment of the conductor that lies between \( x = 1.0 \text{ m} \) and \( x = 3.0 \text{ m} \).

An electron moves in a circle of radius \( r = 5.29 \times 10^{-11} \text{ m} \) with speed \( 2.19 \times 10^6 \text{ m/s} \). Treat the circular path as a current loop with a constant current equal to the ratio of the electron’s charge magnitude to the period of the motion. If the circle lies in a uniform magnetic field of magnitude \( B = 7.10 \text{ mT} \), what is the maximum possible magnitude of the torque produced on the loop by the field?

An electron moves in a circle of radius \( r = 5.29 \times 10^{-11} \text{ m} \) with speed \( 2.19 \times 10^6 \text{ m/s} \). Treat the circular path as a current loop with a constant current equal to the ratio of the electron’s charge magnitude to the period of the motion. If the circle lies in a uniform magnetic field of magnitude \( B = 7.10 \text{ mT} \), what is the maximum possible magnitude of the torque produced on the loop by the field?

Figure 28-45 Problem 49.

Figure 28-46 Problem 51.

A 0.250 kg wood cylinder of mass \( m = 0.250 \text{ kg} \) and length \( L = 0.100 \text{ m} \), with \( N = 10.0 \) turns of wire wrapped around it longitudinally, so that the plane of the wire coil contains the long central axis of the cylinder. The cylinder is released on a plane inclined at an angle \( \theta \) to the horizontal, with the plane of the coil parallel to the incline plane. If there is a vertical uniform magnetic field of magnitude 0.500 T, what is the least current \( i \) through the coil that keeps the cylinder from rolling down the plane?

Figure 28-46 Problem 51.
60 Figure 28-49 shows a current loop ABCDEFA carrying a current \( i = 5.00 \text{ A} \). The sides of the loop are parallel to the coordinate axes shown, with \( AB = 20.0 \text{ cm} \), \( BC = 30.0 \text{ cm} \), and \( FA = 10.0 \text{ cm} \). In unit-vector notation, what is the magnetic dipole moment of this loop? (Hint: Imagine equal and opposite currents \( i \) in the line segment \( AD \); then treat the two rectangular loops \( ABCDA \) and \( ADEFA \).)

61 SSM The coil in Fig. 28-50 carries current \( i = 2.00 \text{ A} \) in the direction indicated, is parallel to an \( xz \) plane, has 3.00 turns and an area of \( 4.00 \times 10^{-3} \text{ m}^2 \), and lies in a uniform magnetic field \( \vec{B} = (2.00\hat{i} - 3.00\hat{j} - 4.00\hat{k}) \text{ mT} \). What are (a) the orientation energy of the coil in the magnetic field and (b) the torque (in unit-vector notation) on the coil due to the magnetic field?

62 In Fig. 28-51a, two concentric coils, lying in the same plane, carry currents in opposite directions. The current in the larger coil 1 is fixed. Current \( i_2 \) in coil 2 can be varied. Figure 28-51b gives the net magnetic moment of the two-coil system as a function of \( i_2 \). The vertical axis scale is set by \( \mu_{net,1} = 2.0 \times 10^{-5} \text{ A} \cdot \text{m}^2 \), and the horizontal axis scale is set by \( i_{20} = 10.0 \text{ mA} \). If the current in coil 2 is then reversed, what is the magnitude of the net magnetic moment of the two-coil system when \( i_2 = 7.0 \text{ mA} \)?

63 A circular loop of wire having a radius of 8.0 cm carries a current of 0.20 A. A vector of unit length and parallel to the dipole moment \( \vec{\mu} \) of the loop is given by \( 0.60\hat{i} - 0.80\hat{j} \). (This unit vector gives the orientation of the dipole moment vector.) If the loop is located in a uniform magnetic field given by \( \vec{B} = (0.25 \text{ T})\hat{i} + (0.30 \text{ T})\hat{k} \), find (a) the torque on the loop (in unit-vector notation) and (b) the orientation energy of the loop.

64 Figure 28-52 gives the orientation energy \( U \) of a magnetic dipole in an external magnetic field \( \vec{B} \), as a function of angle \( \phi \) between the directions of \( \vec{B} \) and the dipole moment. The vertical axis scale is set by \( U_0 = 2.0 \times 10^{-4} \text{ J} \). The dipole can be rotated about an axle with negligible friction in order to change \( \phi \). Counter-clockwise rotation from \( \phi = 0 \) yields positive values of \( \phi \), and clockwise rotations yield negative values. The dipole is to be released at angle \( \phi = 0 \) with a rotational kinetic energy of \( 6.7 \times 10^{-4} \text{ J} \), so that it rotates counterclockwise. To what maximum value of \( \phi \) will it rotate? (In the language of Module 8-3, what value \( \phi \) is the turning point in the potential well of Fig. 28-52?)

65 SSM ILW A wire of length 25.0 cm carrying a current of 4.51 mA is to be formed into a circular coil placed in a uniform magnetic field \( \vec{B} \) of magnitude 5.71 mT. If the torque on the coil from the field is maximized, what are (a) the angle between \( \vec{B} \) and the coil’s magnetic dipole moment and (b) the number of turns in the coil? (c) What is the magnitude of that maximum torque?

Additional Problems

66 A proton of charge \(+e\) and mass \( m \) enters a uniform magnetic field \( \vec{B} = Bi \) with an initial velocity \( \vec{v} = v_{0i}\hat{i} + v_{0j}\hat{j} \). Find an expression in unit-vector notation for its velocity \( \vec{v} \) at any later time \( t \).

67 A stationary circular wall clock has a face with a radius of 15 cm. Six turns of wire are wound around its perimeter; the wire carries a current of 2.0 A in the clockwise direction. The clock is located where there is a constant, uniform external magnetic field of magnitude 70 mT (but the clock still keeps perfect time). At exactly 1:00 P.M., the hour hand of the clock points in the direction of the external magnetic field. (a) After how many minutes will the minute hand point in the direction of the torque on the winding due to the magnetic field? (b) Find the torque magnitude.

68 A wire lying along a \( y \) axis from \( y = 0 \) to \( y = 0.250 \text{ m} \) carries a current of 2.00 mA in the negative direction of the axis. The wire fully lies in a nonuniform magnetic field that is given by \( \vec{B} = (0.300 \text{ T/m})\hat{y} + (0.400 \text{ T/m})\hat{j} \). In unit-vector notation, what is the magnetic force on the wire?

69 Atom 1 of mass 35 u and atom 2 of mass 37 u are both singly ionized with a charge of \(+e\). After being introduced into a mass spectrometer (Fig. 28-12) and accelerated from rest through a potential difference \( V = 7.3 \text{ kV} \), each ion follows a circular path in a uniform magnetic field of magnitude \( B = 0.50 \text{ T} \). What is the distance \( \Delta x \) between the points where the ions strike the detector?

70 An electron with kinetic energy 2.5 keV moving along the positive direction of an \( x \) axis enters a region in which a uniform electric field of magnitude 10 kV/m is in the negative direction of the \( y \) axis. A uniform magnetic field \( \vec{B} \) is to be set up to keep the electron moving along the \( x \) axis, and the direction of \( \vec{B} \) is to be chosen to minimize the required magnitude of \( \vec{B} \). In unit-vector notation, what \( \vec{B} \) should be set up?

71 Physicist S. A. Goudsmit devised a method for measuring the mass of heavy ions by timing their period of revolution in a known magnetic field. A singly charged ion of iodine makes 7.00 rev in a 45.0 mT field in 1.29 ms. Calculate its mass in atomic mass units.
72 A beam of electrons whose kinetic energy is \( K \) emerges from a thin-foil “window” at the end of an accelerator tube. A metal plate at distance \( d \) from this window is perpendicular to the direction of the emerging beam (Fig. 28-53). (a) Show that we can prevent the beam from hitting the plate if we apply a uniform magnetic field such that

\[
B \geq \sqrt{\frac{2mK}{e^2d^2}}.
\]

in which \( m \) and \( e \) are the electron mass and charge. (b) How should \( B \) be oriented?

73 SSM At time \( t = 0 \), an electron with kinetic energy 12 keV moves through \( x = 0 \) in the positive direction of an x axis that is parallel to the horizontal component of Earth’s magnetic field \( \vec{B} \). The field’s vertical component is downward and has magnitude 55.0 \( \mu \)T. (a) What is the magnitude of the electron’s acceleration due to \( \vec{B} \)? (b) What is the electron’s distance from the x axis when the electron reaches coordinate \( x = 20 \) cm?

74 A particle with charge 2.0 C moves through a uniform magnetic field. At one instant the velocity of the particle is \( \vec{v} = (2.0i + 4.0j + 6.0k) \) m/s and the magnetic force on the particle is \( (4.0i - 20j + 12k) \) N. The x and y components of the magnetic field are equal. What is \( \vec{B} \)?

75 A proton, a deuteron (\( q = +e, \ m = 2.0 \) u), and an alpha particle (\( q = +2e, \ m = 4.0 \) u) all having the same kinetic energy enter a region of uniform magnetic field \( \vec{B} \), moving perpendicular to \( \vec{B} \). What is the ratio of (a) the radius \( r_p \) of the proton path to the radius \( r_a \) of the proton path and (b) the radius \( r_v \) of the alpha particle path to \( r_a \)?

76 Bainbridge’s mass spectrometer, shown in Fig. 28-54, separates ions having the same velocity. The ions, after entering through slits, \( S_1 \) and \( S_2 \), pass through a velocity selector composed of an electric field produced by the charged plates \( P \) and \( P' \), and a magnetic field \( \vec{B} \) perpendicular to the electric field and the ion path. The ions that then pass undeflected through the crossed \( \vec{E} \) and \( \vec{B} \) fields enter into a region where a second magnetic field \( \vec{B}' \) exists, where they are made to follow circular paths. A photographic plate (or a modern detector) registers their arrival. Show that, for the ions, \( q/m = E/rBB' \), where \( r \) is the radius of the circular orbit.

77 SSM In Fig. 28-55, an electron moves at speed \( \vec{v} = 100 \) m/s along an x axis through uniform electric and magnetic fields. The magnetic field \( \vec{B} \) is directed into the page and has magnitude 5.00 T. In unit-vector notation, what is the electric field?

78 (a) In Fig. 28-8, show that the ratio of the Hall electric field magnitude \( E \) to the magnitude \( E_C \) of the electric field responsible for moving charge (the current) along the length of the strip is

\[
\frac{E}{E_C} = \frac{B}{npe}.
\]

where \( \rho \) is the resistivity of the material and \( n \) is the number density of the charge carriers. (b) Compute this ratio numerically for Problem 13. (See Table 26-1.)

79 SSM A proton, a deuteron (\( q = +e, \ m = 2.0 \) u), and an alpha particle (\( q = +2e, \ m = 4.0 \) u) are accelerated through the same potential difference and then enter the same region of uniform magnetic field \( \vec{B} \), moving perpendicular to \( \vec{B} \). What is the ratio of (a) the proton’s kinetic energy \( K_p \) to the alpha particle’s kinetic energy \( K_\alpha \) and (b) the deuteron’s kinetic energy \( K_d \) to \( K_\alpha \)? If the radius of the proton’s circular path is 10 cm, what is the radius of (c) the deuteron’s path and (d) the alpha particle’s path?

80 An electron is moving at \( 7.20 \times 10^6 \) m/s in a magnetic field of strength 83.0 mT. What is the (a) maximum and (b) minimum magnitude of the force acting on the electron due to the field? (c) At one point the electron has an acceleration of magnitude \( 4.90 \times 10^4 \) m/s\(^2\). What is the angle between the electron’s velocity and the magnetic field?

81 A 5.0 \( \mu \)C particle moves through a region containing the uniform magnetic field \( -20 \) mT and the uniform electric field \( \vec{E} = 300i + 120j \) mV/m. At a certain instant the velocity of the particle is \( (7i - 12j + 7.0k) \) km/s. At that instant and in unit-vector notation, what is the net electromagnetic force (the sum of the electric and magnetic forces) on the particle?

82 In a Hall-effect experiment, a current of 3.0 A sent lengthwise through a conductor 1.0 cm wide, 4.0 cm long, and 10 \( \mu \)m thick produces a transverse (across the width) Hall potential difference of 10 \( \mu \)V when a magnetic field of 1.5 T is passed perpendicularly through the thickness of the conductor. From these data, find (a) the drift velocity of the charge carriers and (b) the number density of charge carriers. (c) Show on a diagram the polarity of the Hall potential difference with assumed current and magnetic field directions, assuming also that the charge carriers are electrons.

83 SSM A particle of mass 6.0 g moves at 4.0 km/s in an xy plane, in a region with a uniform magnetic field given by 5.0i mT. At one instant, when the particle’s velocity is directed \( 37^\circ \) counterclockwise from the positive direction of the x axis, the magnetic force on the particle is 0.48 kN. What is the particle’s charge?

84 A wire lying along an x axis from \( x = 0 \) to \( x = 1.0 \) m carries a current of 3.00 A in the positive x direction. The wire is immersed in a nonuniform magnetic field that is given by \( \vec{B} = (4.00 \text{T/m}^2)x^2y - (0.600 \text{T/m}^3)x^2z \). In unit-vector notation, what is the magnetic force on the wire?

85 At one instant, \( \vec{v} = (-2.00i + 4.00j - 6.00k) \) m/s is the velocity of a proton in a uniform magnetic field \( \vec{B} = (2.00i - 4.00j + 8.00k) \) mT. At that instant, what are (a) the magnitude of \( \vec{F} \) acting on the proton, in unit-vector notation, (b) the angle between \( \vec{v} \) and \( \vec{F} \), and (c) the angle between \( \vec{v} \) and \( \vec{B} \)?

86 An electron has velocity \( \vec{v} = (32i + 40j) \) km/s as it enters a uniform magnetic field \( \vec{B} = 60i \mu \text{T} \). What are (a) the radius of the helical path taken by the electron and (b) the pitch of that path? (c) To an observer looking into the magnetic field region from the entrance point of the electron, does the electron spiral clockwise or counterclockwise as it moves?
87 Figure 28-56 shows a homopolar generator, which has a solid conducting disk as rotor and which is rotated by a motor (not shown). Conducting brushes connect this emf device to a circuit through which the device drives current. The device can produce a greater emf than wire loop rotors because they can spin at a much higher angular speed without rupturing. The disk has radius \( R = 0.250 \text{ m} \) and rotation frequency \( f = 4000 \text{ Hz} \), and the device is in a uniform magnetic field of magnitude \( B = 60.0 \text{ mT} \) that is perpendicular to the disk. As the disk is rotated, conduction electrons along the conducting path (dashed line) are forced to move through the magnetic field. (a) For the indicated rotation, is the magnetic force on those electrons up or down in the figure? (b) Is the magnitude of that force greater at the rim or near the center of the disk? (c) What is the work per unit charge done by that force in moving charge along the radial line, between the rim and the center? (d) What, then, is the emf of the device? (e) If the current is 50.0 A, what is the power at which electrical energy is being produced?

88 In Fig. 28-57, the two ends of a U-shaped wire of mass \( m = 10.0 \text{ g} \) and length \( L = 20.0 \text{ cm} \) are immersed in mercury (which is a conductor). The wire is in a uniform field of magnitude \( B = 0.100 \text{ T} \). A switch (unshown) is rapidly closed and then reopened, sending a pulse of current through the wire, which causes the wire to jump upward. If jump height \( h = 3.00 \text{ m} \), how much charge was in the pulse? Assume that the duration of the pulse is much less than the time of flight. Consider the definition of impulse (Eq. 9-30) and its relationship with momentum (Eq. 9-31). Also consider the relationship between charge and current (Eq. 26-2).

89 In Fig. 28-58, an electron of mass \( m \), charge \( -e \), and low (negligible) speed enters the region between two plates of potential difference \( V \) and plate separation \( d \), initially headed directly toward the top plate. A uniform magnetic field of magnitude \( B \) is normal to the plane of the figure. Find the minimum value of \( B \) such that the electron will not strike the top plate.

90 A particle of charge \( q \) moves in a circle of radius \( r \) with speed \( v \). Treating the circular path as a current loop with an average current, find the maximum torque exerted on the loop by a uniform field of magnitude \( B \).

91 In a Hall-effect experiment, express the number density of charge carriers in terms of the Hall-effect electric field magnitude \( E \), the current density magnitude \( J \), and the magnetic field magnitude \( B \).

92 An electron that is moving through a uniform magnetic field has velocity \( \vec{v} = (40 \text{ km/s})\mathbf{i} + (35 \text{ km/s})\mathbf{j} \) when it experiences a force \( \vec{F} = -(4.2 \text{ fN})\mathbf{i} + (4.8 \text{ fN})\mathbf{j} \) due to the magnetic field. If \( B_x = 0 \), calculate the magnetic field \( \vec{B} \).
CHAPTER 29

Magnetic Fields Due to Currents

29-1 MAGNETIC FIELD DUE TO A CURRENT

Learning Objectives

After reading this module, you should be able to . . .

29.01 Sketch a current-length element in a wire and indicate the direction of the magnetic field that it sets up at a given point near the wire.
29.02 For a given point near a wire and a given current-element in the wire, determine the magnitude and direction of the magnetic field due to that element.
29.03 Identify the magnitude of the magnetic field set up by a current-length element at a point in line with the direction of that element.
29.04 For a point to one side of a long straight wire carrying current, apply the relationship between the magnetic field magnitude, the current, and the distance to the point.
29.05 For a point to one side of a long straight wire carrying current, use a right-hand rule to determine the direction of the field vector.
29.06 Identify that around a long straight wire carrying current, the magnetic field lines form circles.
29.07 For a point to one side of the end of a semi-infinite wire carrying current, apply the relationship between the magnetic field magnitude, the current, and the distance to the point.
29.08 For the center of curvature of a circular arc of wire carrying current, apply the relationship between the magnetic field magnitude, the current, the radius of curvature, and the angle subtended by the arc (in radians).
29.09 For a point to one side of a short straight wire carrying current, integrate the Biot–Savart law to find the magnetic field set up at the point by the current.

Key Ideas

- The magnetic field set up by a current-carrying conductor can be found from the Biot–Savart law. This law asserts that the contribution $d\mathbf{B}$ to the field produced by a current-length element $i\,d\mathbf{s}$ at a point $P$ located a distance $r$ from the current element is

$$d\mathbf{B} = \frac{\mu_0}{4\pi} \frac{i\,d\mathbf{s} \times \hat{r}}{r^2} \quad \text{(Biot–Savart law)}.$$  

Here $\hat{r}$ is a unit vector that points from the element toward $P$. The quantity $\mu_0$, called the permeability constant, has the value $4\pi \times 10^{-7} \, \text{T} \cdot \text{m/A} = 1.26 \times 10^{-6} \, \text{T} \cdot \text{m/A}$.

- For a long straight wire carrying a current $i$, the Biot–Savart law gives, for the magnitude of the magnetic field at a perpendicular distance $R$ from the wire,

$$B = \frac{\mu_0 i}{2\pi R} \quad \text{(at center of circular arc).}$$

What Is Physics?

One basic observation of physics is that a moving charged particle produces a magnetic field around itself. Thus a current of moving charged particles produces a magnetic field around the current. This feature of electromagnetism, which is the combined study of electric and magnetic effects, came as a surprise to the people who discovered it. Surprise or not, this feature has become enormously important in everyday life because it is the basis of countless electromagnetic devices. For example, a magnetic field is produced in maglev trains and other devices used to lift heavy loads.

Our first step in this chapter is to find the magnetic field due to the current in a very small section of current-carrying wire. Then we shall find the magnetic field due to the entire wire for several different arrangements of the wire.
Calculating the Magnetic Field Due to a Current

Figure 29-1 shows a wire of arbitrary shape carrying a current \( i \). We want to find the magnetic field \( \vec{B} \) at a nearby point \( P \). We first mentally divide the wire into differential elements \( ds \) and then define for each element a length vector \( d\vec{s} \) that has length \( ds \) and whose direction is the direction of the current in \( ds \). We can then define a differential current-length element to be \( i\,d\vec{s} \); we wish to calculate the field \( d\vec{B} \) produced at \( P \) by a typical current-length element. From experiment we find that magnetic fields, like electric fields, can be superimposed to find a net field. Thus, we can calculate the net field at \( P \) by summing, via integration, the contributions \( d\vec{B} \) from all the current-length elements. However, this summation is more challenging than the process associated with electric fields because of a complexity; whereas a charge element \( dq \) producing an electric field is a scalar, a current-length element \( i\,d\vec{s} \) producing a magnetic field is a vector, being the product of a scalar and a vector.

**Magnitude.** The magnitude of the field \( d\vec{B} \) produced at point \( P \) at distance \( r \) by a current-length element \( i\,d\vec{s} \) turns out to be

\[
dB = \frac{\mu_0}{4\pi} \frac{i\,d\vec{s} \sin \theta}{r^2},
\]

where \( \theta \) is the angle between the directions of \( d\vec{s} \) and \( \hat{r} \), a unit vector that points from \( ds \) toward \( P \). Symbol \( \mu_0 \) is a constant, called the **permeability constant**, whose value is defined to be exactly

\[
\mu_0 = 4\pi \times 10^{-7} \text{ T} \cdot \text{m/A} = 1.26 \times 10^{-6} \text{ T} \cdot \text{m/A}.
\]  

**Direction.** The direction of \( d\vec{B} \), shown as being into the page in Fig. 29-1, is that of the cross product \( d\vec{s} \times \hat{r} \). We can therefore write Eq. 29-1 in vector form as

\[
d\vec{B} = \frac{\mu_0}{4\pi} \frac{i\,d\vec{s} \times \hat{r}}{r^2} \quad \text{(Biot–Savart law).} \tag{29-3}
\]

This vector equation and its scalar form, Eq. 29-1, are known as the **law of Biot and Savart** (rhymes with “Leo and bazaar”). The law, which is experimentally deduced, is an inverse-square law. We shall use this law to calculate the net magnetic field \( \vec{B} \) produced at a point by various distributions of current.

Here is one easy distribution: If current in a wire is either directly toward or directly away from a point \( P \) of measurement, can you see from Eq. 29-1 that the magnetic field at \( P \) from the current is simply zero (the angle \( \theta \) is either 0° for toward or 180° for away, and both result in \( \sin \theta = 0 \)?)

**Magnetic Field Due to a Current in a Long Straight Wire**

Shortly we shall use the law of Biot and Savart to prove that the magnitude of the magnetic field at a perpendicular distance \( R \) from a long (infinite) straight wire carrying a current \( i \) is given by

\[
B = \frac{\mu_0 i}{2\pi R} \quad \text{(long straight wire).} \tag{29-4}
\]

The field magnitude \( B \) in Eq. 29-4 depends only on the current and the perpendicular distance \( R \) of the point from the wire. We shall show in our derivation that the field lines of \( \vec{B} \) form concentric circles around the wire, as Fig. 29-2 shows.
and as the iron filings in Fig. 29-3 suggest. The increase in the spacing of the lines in Fig. 29-2 with increasing distance from the wire represents the $1/R$ decrease in the magnitude of $\vec{B}$ predicted by Eq. 29-4. The lengths of the two vectors $\vec{B}$ in the figure also show the $1/R$ decrease.

**Directions.** Plugging values into Eq. 29-4 to find the field magnitude $B$ at a given radius is easy. What is difficult for many students is finding the direction of a field vector $\vec{B}$ at a given point. The field lines form circles around a long straight wire, and the field vector at any point on a circle must be tangent to the circle. That means it must be perpendicular to a radial line extending to the point from the wire. But there are two possible directions for that perpendicular vector, as shown in Fig. 29-4. One is correct for current into the figure, and the other is correct for current out of the figure. How can you tell which is which? Here is a simple right-hand rule for telling which vector is correct:

**Curlèd-straight right-hand rule:** Grasp the element in your right hand with your extended thumb pointing in the direction of the current. Your fingers will then naturally curl around in the direction of the magnetic field lines due to that element.

The result of applying this right-hand rule to the current in the straight wire of Fig. 29-2 is shown in a side view in Fig. 29-5a. To determine the direction of the magnetic field $\vec{B}$ set up at any particular point by this current, mentally wrap your right hand around the wire with your thumb in the direction of the current. Let your fingertips pass through the point; their direction is then the direction of the magnetic field at that point. In the view of Fig. 29-2, $\vec{B}$ at any point is **tangent to a magnetic field line**; in the view of Fig. 29-5, it is **perpendicular to a dashed radial line connecting the point and the current.**
Proof of Equation 29-4

Figure 29-6, which is just like Fig. 29-1 except that now the wire is straight and of infinite length, illustrates the task at hand. We seek the field \( \vec{B} \) at point \( P \), a perpendicular distance \( R \) from the wire. The magnitude of the differential magnetic field produced at \( P \) by the current-length element \( i \, ds \) located a distance \( r \) from \( P \) is given by Eq. 29-1:

\[
\frac{dB}{r} = \frac{\mu_0}{4\pi} i \, ds \sin \theta.
\]

The direction of \( dB \) in Fig. 29-6 is that of the vector \( ds \times \hat{r} \) — namely, directly into the page.

Note that \( dB \) at point \( P \) has this same direction for all the current-length elements into which the wire can be divided. Thus, we can find the magnitude of the magnetic field produced at \( P \) by the current-length elements in the upper half of the infinitely long wire by integrating \( dB \) in Eq. 29-1 from 0 to \( \infty \).

Now consider a current-length element in the lower half of the wire, one that is as far below \( P \) as \( ds \) is above \( P \). By Eq. 29-3, the magnetic field produced at \( P \) by this current-length element has the same magnitude and direction as that from element \( i \, ds \) in Fig. 29-6. Further, the magnetic field produced by the lower half of the wire is exactly the same as that produced by the upper half. To find the magnitude of the total magnetic field \( \vec{B} \) at \( P \), we need only multiply the result of our integration by 2. We get

\[
B = 2 \int_0^\infty dB = \frac{\mu_0 i}{2\pi} \int_0^\infty \frac{\sin \theta \, ds}{r^2}.
\]

(29-5)

The variables \( \theta, s, \) and \( r \) in this equation are not independent; Fig. 29-6 shows that they are related by

\[
r = \sqrt{s^2 + R^2}
\]

and

\[
\sin \theta = \sin(\pi - \theta) = \frac{R}{\sqrt{s^2 + R^2}}.
\]

With these substitutions and integral 19 in Appendix E, Eq. 29-5 becomes

\[
B = \frac{\mu_0 i}{2\pi} \int_0^\infty \frac{R \, ds}{(s^2 + R^2)^{3/2}}
\]

\[
= \frac{\mu_0 i}{2\pi R} \left[ \frac{s}{(s^2 + R^2)^{1/2}} \right]_0^s = \frac{\mu_0 i}{2\pi R},
\]

(29-6)

as we wanted. Note that the magnetic field at \( P \) due to either the lower half or the upper half of the infinite wire in Fig. 29-6 is half this value; that is,

\[
B = \frac{\mu_0 i}{4\pi R} \quad \text{(semi-infinite straight wire).}
\]

(29-7)

Magnetic Field Due to a Current in a Circular Arc of Wire

To find the magnetic field produced at a point by a current in a curved wire, we would again use Eq. 29-1 to write the magnitude of the field produced by a single current-length element, and we would again integrate to find the net field produced by all the current-length elements. That integration can be difficult, depending on the shape of the wire; it is fairly straightforward, however, when the wire is a circular arc and the point is the center of curvature.

Figure 29-7a shows such an arc-shaped wire with central angle \( \phi \), radius \( R \), and center \( C \), carrying current \( i \). At \( C \), each current-length element \( i \, ds \) of the wire produces a magnetic field of magnitude \( dB \) given by Eq. 29-1. Moreover, as Fig. 29-7b shows, no matter where the element is located on the wire, the angle \( \theta \)
between the vectors $\vec{ds}$ and $\hat{r}$ is $90^\circ$; also, $r = R$. Thus, by substituting $R$ for $r$ and $90^\circ$ for $\theta$ in Eq. 29-1, we obtain

$$dB = \frac{\mu_0}{4\pi} \frac{i ds \sin 90^\circ}{R^2} = \frac{\mu_0}{4\pi} \frac{i ds}{R^2}. \tag{29-8}$$

The field at $C$ due to each current-length element in the arc has this magnitude.

**Directions.** How about the direction of the differential field set up by an element? From above we know that the vector must be perpendicular to a radial line extending through point $C$ from the element, either into the plane of Fig. 29-7a or out of it. To tell which direction is correct, we use the right-hand rule for any of the elements, as shown in Fig. 29-7c. Grasping the wire with the thumb in the direction of the current and bringing the fingers into the region near $C$, we see that the vector due to any of the differential elements is out of the plane of the figure, not into it.

**Total Field.** To find the total field at $C$ due to all the elements on the arc, we need to add all the differential field vectors. However, because the vectors are all in the same direction, we do not need to find components. We just sum the magnitudes $dB$ as given by Eq. 29-8. Since we have a vast number of those magnitudes, we sum via integration. We want the result to indicate how the total field depends on the angle $\phi$ of the arc (rather than the arc length). So, in Eq. 29-8 we switch from $ds$ to $d\phi$ by using the identity $ds = R d\phi$. The summation by integration then becomes

$$B = \int dB = \int_0^\phi \frac{\mu_0}{4\pi} \frac{iR d\phi}{R^2} = \frac{\mu_0}{4\pi R} \int_0^\phi d\phi.$$

Integrating, we find that

$$B = \frac{\mu_0 i\phi}{4\pi R} \quad \text{(at center of circular arc).} \quad \tag{29-9}$$

**Heads Up.** Note that this equation gives us the magnetic field only at the center of curvature of a circular arc of current. When you insert data into the equation, you must be careful to express $\phi$ in radians rather than degrees. For example, to find the magnitude of the magnetic field at the center of a full circle of current, you would substitute $2\pi$ rad for $\phi$ in Eq. 29-9, finding

$$B = \frac{\mu_0 i(2\pi)}{4\pi R} = \frac{\mu_0 i}{2R} \quad \text{(at center of full circle).} \quad \tag{29-10}$$

**Sample Problem 29.01 Magnetic field at the center of a circular arc of current**

The wire in Fig. 29-8a carries a current $i$ and consists of a circular arc of radius $R$ and central angle $\pi/2$ rad, and two straight sections whose extensions intersect the center $C$ of the arc. What magnetic field $\vec{B}$ (magnitude and direction) does the current produce at $C$?

**KEY IDEAS**

We can find the magnetic field $\vec{B}$ at point $C$ by applying the Biot–Savart law of Eq. 29-3 to the wire, point by point along the full length of the wire. However, the application of Eq. 29-3 can be simplified by evaluating $\vec{B}$ separately for the three distinguishable sections of the wire—namely, (1) the straight section at the left, (2) the straight section at the right, and (3) the circular arc.

**Straight sections:** For any current-length element in section 1, the angle $\theta$ between $\vec{ds}$ and $\hat{r}$ is zero (Fig. 29-8b); so Eq. 29-1 gives us

$$dB_1 = \frac{\mu_0}{4\pi} \frac{i ds \sin \theta}{r^2} = \frac{\mu_0}{4\pi} \frac{i ds \sin 0}{r^2} = 0.$$

Thus, the current along the entire length of straight section 1 contributes no magnetic field at $C$: $B_1 = 0$. 

The circular arc; the field is into the page there.

(your right hand as in Fig. 29-8 displayed in Fig. 29-5. Mentally grasp the circular arc with the angle at the arc’s center is $\pi/2$ rad. Thus from Eq. 29-9, the magnitude of the magnetic field $B_3$ at the center of a circular arc leads to $B_3 = \frac{\mu_0 i (\pi/2)}{4\pi R} = \frac{\mu_0 i}{8R}$.)

Circular arc: Application of the Biot–Savart law to evaluate the magnetic field at the center of a circular arc leads to Eq. 29-9 ($B = \mu_0 i (\phi/4\pi R)$). Here the central angle $\phi$ of the arc is $\pi/2$ rad. Thus from Eq. 29-9, the magnitude of the magnetic field $B_3$ at the arc’s center $C$ is

$$B_3 = \frac{\mu_0 i (\pi/2)}{4\pi R} = \frac{\mu_0 i}{8R}.$$ 

To find the direction of $B_3$, we apply the right-hand rule displayed in Fig. 29-5. Mentally grasp the circular arc with your right hand as in Fig. 29-8c, with your thumb in the direction of the current. The direction in which your fingers curl around the wire indicates the direction of the magnetic field lines around the wire. They form circles around the wire, coming out of the page above the arc and going into the page inside the arc. In the region of point $C$ (inside the arc), your fingertips point into the plane of the page. Thus, $B_3$ is directed into that plane.

Net field: Generally, we combine multiple magnetic fields as vectors. Here, however, only the circular arc produces a magnetic field at point $C$. Thus, we can write the magnitude of the net field $B$ as

$$B = B_1 + B_2 + B_3 = 0 + 0 + \frac{\mu_0 i}{8R} = \frac{\mu_0 i}{8R}.$$ (Answer)

The direction of $B$ is the direction of $B_3$—namely, into the plane of Fig. 29-8.

Sample Problem 29.02  Magnetic field off to the side of two long straight currents

Figure 29-9a shows two long parallel wires carrying currents $i_1$ and $i_2$ in opposite directions. What are the magnitude and direction of the net magnetic field at point $P$? Assume the following values: $i_1 = 15$ A, $i_2 = 32$ A, and $d = 5.3$ cm.

KEY IDEAS

(1) The net magnetic field $\vec{B}$ at point $P$ is the vector sum of the magnetic fields due to the currents in the two wires. (2) We can find the magnetic field due to any current by applying the Biot–Savart law to the current. For points near the current in a long straight wire, that law leads to Eq. 29-4.

Finding the vectors: In Fig. 29-9a, point $P$ is distance $R$ from both currents $i_1$ and $i_2$. Thus, Eq. 29-4 tells us that at point $P$ those currents produce magnetic fields $\vec{B}_1$ and $\vec{B}_2$ with magnitudes

$$B_1 = \frac{\mu_0 |i_1|}{2\pi R} \quad \text{and} \quad B_2 = \frac{\mu_0 |i_2|}{2\pi R}.$$ 

In the right triangle of Fig. 29-9a, note that the base angles (between sides $R$ and $d$) are both $45^\circ$. This allows us to write $\cos 45^\circ = R/d$ and replace $R$ with $d \cos 45^\circ$. Then the field magnitudes $B_1$ and $B_2$ become

$$B_1 = \frac{\mu_0 |i_1|}{2\pi d \cos 45^\circ} \quad \text{and} \quad B_2 = \frac{\mu_0 |i_2|}{2\pi d \cos 45^\circ}.$$
29-2 FORCE BETWEEN TWO PARALLEL CURRENTS

Learning Objectives

After reading this module, you should be able to . . .

29.10 Given two parallel or antiparallel currents, find the magnetic field of the first current at the location of the second current and then find the force acting on that second current.

29.11 Identify that parallel currents attract each other, and antiparallel currents repel each other.

29.12 Describe how a rail gun works.

Key Ideas

- Parallel wires carrying currents in the same direction attract each other, whereas parallel wires carrying currents in opposite directions repel each other. The magnitude of the force on a length $L$ of either wire is

\[ F_{ba} = i_b L B_a \sin 90^\circ = \frac{\mu_0 L i_a i_b}{2\pi d}, \]

where $d$ is the wire separation, and $i_a$ and $i_b$ are the currents in the wires.

Force Between Two Parallel Currents

Two long parallel wires carrying currents exert forces on each other. Figure 29-10 shows two such wires, separated by a distance $d$ and carrying currents $i_a$ and $i_b$. Let us analyze the forces on these wires due to each other.

We seek first the force on wire $b$ in Fig. 29-10 due to the current in wire $a$. That current produces a magnetic field $B_a$, and it is this magnetic field that actually causes the force we seek. To find the force, then, we need the magnitude and direction of the field $B_a$ at the site of wire $b$. The magnitude of $B_a$ at every point of wire $b$ is, from Eq. 29-4,

\[ B_a = \frac{\mu_0 i_a}{2\pi d}. \] (29-11)
The curled–straight right-hand rule tells us that the direction of $\vec{B}_a$ at wire $b$ is down, as Fig. 29-10 shows. Now that we have the field, we can find the force it produces on wire $b$. Equation 28-26 tells us that the force $\vec{F}_{ba}$ on a length $L$ of wire $b$ due to the external magnetic field $\vec{B}_a$ is

$$\vec{F}_{ba} = i_b \vec{L} \times \vec{B}_a,$$

(29-12)

where $\vec{L}$ is the length vector of the wire. In Fig. 29-10, vectors $\vec{L}$ and $\vec{B}_a$ are perpendicular to each other, and so with Eq. 29-11, we can write

$$F_{ba} = i_b L B_a \sin 90^\circ = \frac{\mu_0 L i_b i_b}{2 \pi d}.$$

(29-13)

The direction of $\vec{F}_{ba}$ is the direction of the cross product $\vec{L} \times \vec{B}_a$. Applying the right-hand rule for cross products to $\vec{L}$ and $\vec{B}_a$ in Fig. 29-10, we see that $\vec{F}_{ba}$ is directly toward wire $a$, as shown.

The general procedure for finding the force on a current-carrying wire is this:

1. To find the force on a current-carrying wire due to a second current-carrying wire, first find the field due to the second wire at the site of the first wire. Then find the force on the first wire due to that field.

We could now use this procedure to compute the force on wire $a$ due to the current in wire $b$. We would find that the force is directly toward wire $b$; hence, the two wires with parallel currents attract each other. Similarly, if the two currents were antiparallel, we could show that the two wires repel each other. Thus, parallel currents attract each other, and antiparallel currents repel each other.

The force acting between currents in parallel wires is the basis for the definition of the ampere, which is one of the seven SI base units. The definition, adopted in 1946, is this: The ampere is that constant current which, if maintained in two straight, parallel conductors of infinite length, of negligible circular cross section, and placed 1 m apart in vacuum, would produce on each of these conductors a force of magnitude $2 \times 10^{-7}$ newton per meter of wire length.

**Rail Gun**

The basics of a rail gun are shown in Fig. 29-11a. A large current is sent out along one of two parallel conducting rails, across a conducting “fuse” (such as a narrow piece of copper) between the rails, and then back to the current source along the second rail. The projectile to be fired lies on the far side of the fuse and fits loosely between the rails. Immediately after the current begins, the fuse element melts and vaporizes, creating a conducting gas between the rails where the fuse had been.

The curled–straight right-hand rule of Fig. 29-5 reveals that the currents in the rails of Fig. 29-11a produce magnetic fields that are directed downward between the rails. The net magnetic field $\vec{B}$ exerts a force $\vec{F}$ on the gas due to the current $i$ through the gas (Fig. 29-11b). With Eq. 29-12 and the right-hand rule for cross products, we find that $\vec{F}$ points outward along the rails. As the gas is forced outward along the rails, it pushes the projectile, accelerating it by as much as $5 \times 10^6$ g, and then launches it with a speed of 10 km/s, all within 1 ms. Someday rail guns may be used to launch materials into space from mining operations on the Moon or an asteroid.

**Checkpoint 1**

The figure here shows three long, straight, parallel, equally spaced wires with identical currents either into or out of the page. Rank the wires according to the magnitude of the force on each due to the currents in the other two wires, greatest first.
29-3 AMPERE’S LAW

Learning Objectives

After reading this module, you should be able to . . .

29.13 Apply Ampere’s law to a loop that encircles current.
29.14 With Ampere’s law, use a right-hand rule for determining the algebraic sign of an encircled current.
29.15 For more than one current within an Amperian loop, determine the net current to be used in Ampere’s law.

29.16 Apply Ampere’s law to a long straight wire with current, to find the magnetic field magnitude inside and outside the wire, identifying that only the current encircled by the Amperian loop matters.

Key Idea

● Ampere’s law states that

\[ \oint \vec{B} \cdot d\vec{s} = \mu_0 i_{\text{enc}} \]  

(Ampere’s law).

The line integral in this equation is evaluated around a closed loop called an Amperian loop. The current \( i \) on the right side is the net current encircled by the loop.

Ampere’s Law

We can find the net electric field due to any distribution of charges by first writing the differential electric field \( d\vec{E} \) due to a charge element and then summing the contributions of \( d\vec{E} \) from all the elements. However, if the distribution is complicated, we may have to use a computer. Recall, however, that if the distribution has planar, cylindrical, or spherical symmetry, we can apply Gauss’ law to find the net electric field with considerably less effort.

Similarly, we can find the net magnetic field due to any distribution of currents by first writing the differential magnetic field \( dB \) (Eq. 29-3) due to a current-length element and then summing the contributions of \( dB \) from all the elements. Again we may have to use a computer for a complicated distribution. However, if the distribution has some symmetry, we may be able to apply Ampere’s law to find the magnetic field with considerably less effort. This law, which can be derived from the Biot–Savart law, has traditionally been credited to André-Marie Ampère (1775–1836), for whom the SI unit of current is named. However, the law actually was advanced by English physicist James Clerk Maxwell. Ampère’s law is

\[ \oint \vec{B} \cdot d\vec{s} = \mu_0 i_{\text{enc}} \]  

(Ampere’s law).

The loop on the integral sign means that the scalar (dot) product \( \vec{B} \cdot d\vec{s} \) is to be integrated around a closed loop, called an Amperian loop. The current \( i_{\text{enc}} \) is the net current encircled by that closed loop.

To see the meaning of the scalar product \( \vec{B} \cdot d\vec{s} \) and its integral, let us first apply Ampere’s law to the general situation of Fig. 29-12. The figure shows cross sections of three long straight wires that carry currents \( i_1, i_2, \) and \( i_3 \) either directly into or directly out of the page. An arbitrary Amperian loop lying in the plane of the page encircles two of the currents but not the third. The counterclockwise direction marked on the loop indicates the arbitrarily chosen direction of integration for Eq. 29-14.

To apply Ampere’s law, we mentally divide the loop into differential vector elements \( d\vec{s} \) that are everywhere directed along the tangent to the loop in the direction of integration. Assume that at the location of the element \( d\vec{s} \) shown in Fig. 29-12, the net magnetic field due to the three currents is \( \vec{B} \). Because the wires are perpendicular to the page, we know that the magnetic
field at \( ds \) due to each current is in the plane of Fig. 29-12; thus, their net magnetic field \( \vec{B} \) at \( ds \) must also be in that plane. However, we do not know the orientation of \( \vec{B} \) within the plane. In Fig. 29-12, \( \vec{B} \) is arbitrarily drawn at an angle \( \theta \) to the direction of \( ds \). The scalar product \( \vec{B} \cdot ds \) on the left side of Eq. 29-14 is equal to \( B \cos \theta ds \). Thus, Ampere’s law can be written as

\[
\oint \vec{B} \cdot ds = \oint B \cos \theta ds = \mu_0 i_{\text{enc}}.
\]  

(29-15)

We can now interpret the scalar product \( \vec{B} \cdot ds \) as being the product of a length \( ds \) of the Amperian loop and the field component \( B \cos \theta \) tangent to the loop. Then we can interpret the integration as being the summation of all such products around the entire loop.

**Signs.** When we can actually perform this integration, we do not need to know the direction of \( \vec{B} \) before integrating. Instead, we arbitrarily assume \( \vec{B} \) to be generally in the direction of integration (as in Fig. 29-12). Then we use the following curled–straight right-hand rule to assign a plus sign or a minus sign to each of the currents that make up the net encircled current \( i_{\text{enc}} \).

![Curl your right hand around the Amperian loop, with the fingers pointing in the direction of integration. A current through the loop in the general direction of your outstretched thumb is assigned a plus sign, and a current generally in the opposite direction is assigned a minus sign.](image)

Finally, we solve Eq. 29-15 for the magnitude of \( B \). If \( B \) turns out positive, then the direction we assumed for \( \vec{B} \) is correct. If it turns out negative, we neglect the minus sign and redraw \( \vec{B} \) in the opposite direction.

**Net Current.** In Fig. 29-13 we apply the curled–straight right-hand rule for Ampere’s law to the situation of Fig. 29-12. With the indicated counterclockwise direction of integration, the net current encircled by the loop is

\[ i_{\text{enc}} = i_1 - i_2. \]

(Current \( i_3 \) is not encircled by the loop.) We can then rewrite Eq. 29-15 as

\[
\oint B \cos \theta ds = \mu_0 (i_1 - i_2).
\]  

(29-16)

You might wonder why, since current \( i_3 \) contributes to the magnetic-field magnitude \( B \) on the left side of Eq. 29-16, it is not needed on the right side. The answer is that the contributions of current \( i_3 \) to the magnetic field cancel out because the integration in Eq. 29-16 is made around the full loop. In contrast, the contributions of an encircled current to the magnetic field do not cancel out.

We cannot solve Eq. 29-16 for the magnitude \( B \) of the magnetic field because for the situation of Fig. 29-12 we do not have enough information to simplify and solve the integral. However, we do know the outcome of the integration; it must be equal to \( \mu_0 (i_1 - i_2) \), the value of which is set by the net current passing through the loop.

We shall now apply Ampere’s law to two situations in which symmetry does allow us to simplify and solve the integral, hence to find the magnetic field.

### Magnetic Field Outside a Long Straight Wire with Current

Figure 29-14 shows a long straight wire that carries current \( i \) directly out of the page. Equation 29-4 tells us that the magnetic field \( \vec{B} \) produced by the current has the same magnitude at all points that are the same distance \( r \) from the wire; that is, the field \( \vec{B} \) has cylindrical symmetry about the wire. We can take advantage of that symmetry to simplify the integral in Ampere’s law (Eqs. 29-14 and 29-15) if we encircle the wire with a concentric circular Amperian loop of radius \( r \), as in Fig. 29-14. The magnetic field then has the same magnitude \( B \) at every point on the loop. We shall integrate counterclockwise, so that \( ds \) has the direction shown in Fig. 29-14.
We can further simplify the quantity $B \cos \theta$ in Eq. 29-15 by noting that $\vec{B}$ is tangent to the loop at every point along the loop, as is $ds$. Thus, $\vec{B}$ and $ds$ are either parallel or antiparallel at each point of the loop, and we shall arbitrarily assume the former. Then at every point the angle $\theta$ between $ds$ and $\vec{B}$ is $0^\circ$, so $\cos \theta = \cos 0^\circ = 1$. The integral in Eq. 29-15 then becomes

$$\oint \vec{B} \cdot ds = \oint B \cos \theta ds = B \oint ds = B(2\pi r).$$

Note that $\oint ds$ is the summation of all the line segment lengths $ds$ around the circular loop; that is, it simply gives the circumference $2\pi r$ of the loop.

Our right-hand rule gives us a plus sign for the current of Fig. 29-14. The right side of Ampere’s law becomes

$$B(2\pi r) = \mu_0 i,$$

or

$$B = \frac{\mu_0 i}{2\pi r} \quad \text{(outside straight wire).} \quad (29-17)$$

With a slight change in notation, this is Eq. 29-4, which we derived earlier—with considerably more effort—using the law of Biot and Savart. In addition, because the magnitude $B$ turned out positive, we know that the correct direction of $\vec{B}$ must be the one shown in Fig. 29-14.

**Magnetic Field Inside a Long Straight Wire with Current**

Figure 29-15 shows the cross section of a long straight wire of radius $R$ that carries a uniformly distributed current $i$ directly out of the page. Because the current is uniformly distributed over a cross section of the wire, the magnetic field $\vec{B}$ produced by the current must be cylindrically symmetrical. Thus, to find the magnetic field at points inside the wire, we can again use an Amperian loop of radius $r$, as shown in Fig. 29-15, where now $r < R$. Symmetry again suggests that $\vec{B}$ is tangent to the loop, as shown; so the left side of Ampere’s law again yields

$$\oint \vec{B} \cdot ds = B \oint ds = B(2\pi r). \quad (29-18)$$

Because the current is uniformly distributed, the current $i_{enc}$ encircled by the loop is proportional to the area encircled by the loop; that is,

$$i_{enc} = i \frac{\pi r^2}{\pi R^2}. \quad (29-19)$$

Our right-hand rule tells us that $i_{enc}$ gets a plus sign. Then Ampere’s law gives us

$$B(2\pi r) = \mu_0 \frac{\pi r^2}{\pi R^2}$$

or

$$B = \left( \frac{\mu_0 i}{2\pi R^2} \right) r \quad \text{(inside straight wire).} \quad (29-20)$$

Thus, inside the wire, the magnitude $B$ of the magnetic field is proportional to $r$, is zero at the center, and is maximum at $r = R$ (the surface). Note that Eqs. 29-17 and 29-20 give the same value for $B$ at the surface.

**Checkpoint 2**

The figure here shows three equal currents $i$ (two parallel and one antiparallel) and four Amperian loops. Rank the loops according to the magnitude of $\oint \vec{B} \cdot ds$ along each, greatest first.
Sample Problem 29.03  Ampere’s law to find the field inside a long cylinder of current

Figure 29-16 shows the cross section of a long conducting cylinder with inner radius \( a = 2.0 \text{ cm} \) and outer radius \( b = 4.0 \text{ cm} \). The cylinder carries a current out of the page, and the magnitude of the current density in the cross section is given by \( J = cr^2 \), with \( c = 3.0 \times 10^6 \text{ A/m}^4 \) and \( r \) in meters. What is the magnetic field \( \vec{B} \) at the dot in Fig. 29-16a, which is at radius \( r = 3.0 \text{ cm} \) from the central axis of the cylinder? 

**KEY IDEAS**

The point at which we want to evaluate \( \vec{B} \) is inside the material of the conducting cylinder, between its inner and outer radii. We note that the current distribution has cylindrical symmetry (it is the same all around the cross section for any given radius). Thus, the symmetry allows us to use Ampere’s law to find \( \vec{B} \) at the point. We first draw the Amperian loop shown in Fig. 29-16b. The loop is concentric with the cylinder and has radius \( r = 3.0 \text{ cm} \) because we want to evaluate \( \vec{B} \) at that distance from the cylinder’s central axis.

Next, we must compute the current \( i_{\text{enc}} \) that is encircled by the Amperian loop. However, we cannot set up a proportionality as in Eq. 29-19, because here the current is not uniformly distributed. Instead, we must integrate the current density magnitude from the cylinder’s inner radius \( a \) to the loop radius \( r \), using the steps shown in Figs. 29-16c through h.

**Calculations:** We write the integral as

\[
i_{\text{enc}} = \int J \, dA = \int_a^r cr^2 (2 \pi r \, dr)
\]

\[
= 2 \pi c \int_a^r r^3 \, dr = 2 \pi c \left[ \frac{r^4}{4} \right]_a^r
\]

\[
= \frac{\pi c (r^4 - a^4)}{2}.
\]

Note that in these steps we took the differential area \( dA \) to be the area of the thin ring in Figs. 29-16d–f and then

---

**Figure 29-16** (a)–(b) To find the magnetic field at a point within this conducting cylinder, we use a concentric Amperian loop through the point. We then need the current encircled by the loop. (c)–(h) Because the current density is nonuniform, we start with a thin ring and then sum (via integration) the currents in all such rings in the encircled area.
replaced it with its equivalent, the product of the ring’s circumference $2\pi r$ and its thickness $dr$.

For the Amperian loop, the direction of integration indicated in Fig. 29-16b is (arbitrarily) clockwise. Applying the right-hand rule for Ampere’s law to that loop, we find that we should take $i_{\text{enc}}$ as negative because the current is directed out of the page but our thumb is directed into the page.

We next evaluate the left side of Ampere’s law as we did in Fig. 29-15, and we again obtain Eq. 29-18. Then Ampere’s law,

$$\oint B \cdot d\vec{s} = \mu_0 i_{\text{enc}},$$

gives us

$$B(2\pi r) = -\frac{\mu_0 \pi}{2} (r^4 - a^4).$$

Solving for $B$ and substituting known data yield

$$B = -\frac{\mu_0 c}{4r} (r^4 - a^4)$$

$$= -\frac{(4\pi \times 10^{-7} \text{T} \cdot \text{m/A})(3.0 \times 10^6 \text{A/m}^2)}{4(0.030 \text{ m})}$$

$$\times [(0.030 \text{ m})^4 - (0.020 \text{ m})^4]$$

$$= -2.0 \times 10^{-5} \text{T}.$$

Thus, the magnetic field $\vec{B}$ at a point 3.0 cm from the central axis has magnitude

$$B = 2.0 \times 10^{-5} \text{T} \quad \text{(Answer)}$$

and forms magnetic field lines that are directed opposite our direction of integration, hence counterclockwise in Fig. 29-16b.

---

### 29-4 SOLENOIDS AND TOROIDS

#### Learning Objectives

After reading this module, you should be able to . . .

29.17 Describe a solenoid and a toroid and sketch their magnetic field lines.
29.18 Explain how Ampere’s law is used to find the magnetic field inside a solenoid.
29.19 Apply the relationship between a solenoid’s internal magnetic field $B$, the current $i$, and the number of turns per unit length $n$ of the solenoid.
29.20 Explain how Ampere’s law is used to find the magnetic field inside a toroid.
29.21 Apply the relationship between a toroid’s internal magnetic field $B$, the current $i$, the radius $r$, and the total number of turns $N$.

#### Key Ideas

- Inside a long solenoid carrying current $i$, at points not near its ends, the magnitude $B$ of the magnetic field is

$$B = \mu_0 in \quad \text{(ideal solenoid)},$$

where $n$ is the number of turns per unit length.

- At a point inside a toroid, the magnitude $B$ of the magnetic field is

$$B = \frac{\mu_0 iN}{2\pi} \frac{1}{r} \quad \text{(toroid)},$$

where $r$ is the distance from the center of the toroid to the point.

#### Solenoids and Toroids

**Magnetic Field of a Solenoid**

We now turn our attention to another situation in which Ampere’s law proves useful. It concerns the magnetic field produced by the current in a long, tightly wound helical coil of wire. Such a coil is called a solenoid (Fig. 29-17). We assume that the length of the solenoid is much greater than the diameter.

Figure 29-18 shows a section through a portion of a “stretched-out” solenoid. The solenoid’s magnetic field is the vector sum of the fields produced by the individual turns (windings) that make up the solenoid. For points very
close to a turn, the wire behaves magnetically almost like a long straight wire, and the lines of $\mathbf{B}$ there are almost concentric circles. Figure 29-18 suggests that the field tends to cancel between adjacent turns. It also suggests that, at points inside the solenoid and reasonably far from the wire, is approximately parallel to the (central) solenoid axis. In the limiting case of an ideal solenoid, which is infinitely long and consists of tightly packed (close-packed) turns of square wire, the field inside the coil is uniform and parallel to the solenoid axis.

At points above the solenoid, such as $P$ in Fig. 29-18, the magnetic field set up by the upper parts of the solenoid turns (these upper turns are marked $\bigcirc$) is directed to the left (as drawn near $P$) and tends to cancel the field set up at $P$ by the lower parts of the turns (these lower turns are marked $\bigotimes$), which is directed to the right (not drawn). In the limiting case of an ideal solenoid, the magnetic field outside the solenoid is zero. Taking the external field to be zero is an excellent assumption for a real solenoid if its length is much greater than its diameter and if we consider external points such as point $P$ that are not at either end of the solenoid. The direction of the magnetic field along the solenoid axis is given by a curled–straight right-hand rule: Grasp the solenoid with your right hand so that your fingers follow the direction of the current in the windings; your extended right thumb then points in the direction of the axial magnetic field.

Figure 29-19 shows the lines of $\mathbf{B}$ for a real solenoid. The spacing of these lines in the central region shows that the field inside the coil is fairly strong and uniform over the cross section of the coil. The external field, however, is relatively weak.

**Ampere’s Law.** Let us now apply Ampere’s law,

$$\oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 i_{\text{enc}}, \quad (29-21)$$

to the ideal solenoid of Fig. 29-20, where $\mathbf{B}$ is uniform within the solenoid and zero outside it, using the rectangular Amperian loop $abcd$. We write $\oint \mathbf{B} \cdot d\mathbf{s}$ as the sum of four integrals, one for each loop segment:

$$\oint \mathbf{B} \cdot d\mathbf{s} = \int_{a}^{b} \mathbf{B} \cdot d\mathbf{s} + \int_{b}^{c} \mathbf{B} \cdot d\mathbf{s} + \int_{c}^{d} \mathbf{B} \cdot d\mathbf{s} + \int_{d}^{a} \mathbf{B} \cdot d\mathbf{s}. \quad (29-22)$$
The first integral on the right of Eq. 29-22 is \( Bh \), where \( B \) is the magnitude of the uniform field \( \vec{B} \) inside the solenoid and \( h \) is the (arbitrary) length of the segment from \( a \) to \( b \). The second and fourth integrals are zero because for every element \( ds \) of these segments, \( \vec{B} \cdot ds \) is either perpendicular to \( ds \) or is zero, and thus the product \( \vec{B} \cdot ds \) is zero. The third integral, which is taken along a segment that lies outside the solenoid, is zero because \( B = 0 \) at all external points. Thus, \( \oint \vec{B} \cdot ds \) for the entire rectangular loop has the value \( Bh \).

Net Current. The net current \( i_{\text{enc}} \) encircled by the rectangular Amperian loop in Fig. 29-20 is not the same as the current \( i \) in the solenoid windings because the windings pass more than once through this loop. Let \( n \) be the number of turns per unit length of the solenoid; then the loop encloses \( nh \) turns and

\[ i_{\text{enc}} = i(nh) \]

Ampere’s law then gives us

\[ Bh = \mu_0 i nh \]

or

\[ B = \mu_0 i n \quad \text{(ideal solenoid)} \]  
(29-23)

Although we derived Eq. 29-23 for an infinitely long ideal solenoid, it holds quite well for actual solenoids if we apply it only at interior points and well away from the solenoid ends. Equation 29-23 is consistent with the experimental fact that the magnetic field magnitude \( B \) within a solenoid does not depend on the diameter or the length of the solenoid and that \( B \) is uniform over the solenoidal cross section. A solenoid thus provides a practical way to set up a known uniform magnetic field for experimentation, just as a parallel-plate capacitor provides a practical way to set up a known uniform electric field.

Magnetic Field of a Toroid

Figure 29-21a shows a toroid, which we may describe as a (hollow) solenoid that has been curved until its two ends meet, forming a sort of hollow bracelet. What magnetic field \( \vec{B} \) is set up inside the toroid (inside the hollow of the bracelet)? We can find out from Ampere’s law and the symmetry of the bracelet.

From the symmetry, we see that the lines of form concentric circles inside the toroid, directed as shown in Fig. 29-21b. Let us choose a concentric circle of radius \( r \) as an Amperian loop and traverse it in the clockwise direction. Ampere’s law (Eq. 29-14) yields

\[ (B)(2\pi r) = \mu_0 iN, \]

where \( i \) is the current in the toroid windings (and is positive for those windings enclosed by the Amperian loop) and \( N \) is the total number of turns. This gives

\[ B = \frac{\mu_0 iN}{2\pi} \frac{1}{r} \quad \text{(toroid).} \]  
(29-24)

In contrast to the situation for a solenoid, \( B \) is not constant over the cross section of a toroid.

It is easy to show, with Ampere’s law, that \( B = 0 \) for points outside an ideal toroid (as if the toroid were made from an ideal solenoid). The direction of the magnetic field within a toroid follows from our curled–straight right-hand rule: Grasp the toroid with the fingers of your right hand curled in the direction of the current in the windings; your extended right thumb points in the direction of the magnetic field.
Sample Problem 29.04  The field inside a solenoid (a long coil of current)

A solenoid has length $L = 1.23$ m and inner diameter $d = 3.55$ cm, and it carries a current $i = 5.57$ A. It consists of five close-packed layers, each with 850 turns along length $L$. What is $B$ at its center?

**Calculation:** Because $B$ does not depend on the diameter of the windings, the value of $n$ for five identical layers is simply five times the value for each layer. Equation 29-23 then tells us

$$B = \mu_0 in = (4\pi \times 10^{-7} \text{T} \cdot \text{m/A})(5.57 \text{ A}) \frac{5 \times 850 \text{ turns}}{1.23 \text{ m}}$$

$$= 2.42 \times 10^{-2} \text{T} = 24.2 \text{ mT}. \quad (\text{Answer})$$

To a good approximation, this is the field magnitude throughout most of the solenoid.

---

29-5 A CURRENT-CARRYING COIL AS A MAGNETIC DIPOLE

**Learning Objectives**

*After reading this module, you should be able to . . .

29.22 Sketch the magnetic field lines of a flat coil that is carrying current.

29.23 For a current-carrying coil, apply the relationship between the dipole moment magnitude $\mu$ and the coil’s current $i$, number of turns $N$, and area per turn $A$.

29.24 For a point along the central axis, apply the relationship between the magnetic field magnitude $B$, the magnetic moment $\mu$, and the distance $z$ from the center of the coil.

**Key Idea**

- The magnetic field produced by a current-carrying coil, which is a magnetic dipole, at a point $P$ located a distance $z$ along the coil’s perpendicular central axis is parallel to the axis and is given by

$$\vec{B}(z) = \frac{\mu_0 \vec{\mu}}{2\pi z^3},$$

where $\vec{\mu}$ is the dipole moment of the coil. This equation applies only when $z$ is much greater than the dimensions of the coil.

**A Current-Carrying Coil as a Magnetic Dipole**

So far we have examined the magnetic fields produced by current in a long straight wire, a solenoid, and a toroid. We turn our attention here to the field produced by a coil carrying a current. You saw in Module 28-8 that such a coil behaves as a magnetic dipole in that, if we place it in an external magnetic field $\vec{B}$, a torque $\vec{\tau}$ given by

$$\vec{\tau} = \vec{\mu} \times \vec{B} \quad (29-25)$$

acts on it. Here $\vec{\mu}$ is the magnetic dipole moment of the coil and has the magnitude $Na$, where $N$ is the number of turns, $i$ is the current in each turn, and $A$ is the area enclosed by each turn. (*Caution:* Don’t confuse the magnetic dipole moment $\vec{\mu}$ with the permeability constant $\mu_0$.)

Recall that the direction of $\vec{\mu}$ is given by a curled–straight right-hand rule: Grasp the coil so that the fingers of your right hand curl around it in the direction of the current; your extended thumb then points in the direction of the dipole moment $\vec{\mu}$. 

---

Additional examples, video, and practice available at *WileyPLUS*
Magnetic Field of a Coil

We turn now to the other aspect of a current-carrying coil as a magnetic dipole. What magnetic field does it produce at a point in the surrounding space? The problem does not have enough symmetry to make Ampere’s law useful; so we must turn to the law of Biot and Savart. For simplicity, we first consider only a coil with a single circular loop and only points on its perpendicular central axis, which we take to be a $z$ axis. We shall show that the magnitude of the magnetic field at such points is

$$B(z) = \frac{\mu_0 i R^2}{2(R^2 + z^2)^{3/2}},$$

in which $R$ is the radius of the circular loop and $z$ is the distance of the point in question from the center of the loop. Furthermore, the direction of the magnetic field $\vec{B}$ is the same as the direction of the magnetic dipole moment $\vec{\mu}$ of the loop.

**Large $z$.** For axial points far from the loop, we have $z \gg R$ in Eq. 29-26. With that approximation, the equation reduces to

$$B(z) = \frac{\mu_0 i R^2}{2z^3}.$$

Recalling that $\pi R^2$ is the area $A$ of the loop and extending our result to include a coil of $N$ turns, we can write this equation as

$$B(z) = \frac{\mu_0}{2\pi} \frac{N i A}{z^3}.$$

Further, because $\vec{B}$ and $\vec{\mu}$ have the same direction, we can write the equation in vector form, substituting from the identity $\mu = NiA$:

$$\vec{B}(z) = \frac{\mu_0}{2\pi} \frac{\vec{\mu}}{z^3} \quad \text{(current-carrying coil).}$$

Thus, we have two ways in which we can regard a current-carrying coil as a magnetic dipole: (1) it experiences a torque when we place it in an external magnetic field; (2) it generates its own intrinsic magnetic field, given, for distant points along its axis, by Eq. 29-27. Figure 29-22 shows the magnetic field of a current loop; one side of the loop acts as a north pole (in the direction of $\vec{\mu}$).
and the other side as a south pole, as suggested by the lightly drawn magnet in
the figure. If we were to place a current-carrying coil in an external magnetic
field, it would tend to rotate just like a bar magnet would.

**Checkpoint 3**

The figure here shows four arrangements of circular loops of radius \( r \) or \( 2r \), centered
on vertical axes (perpendicular to the loops) and carrying identical currents in the di-
rections indicated. Rank the arrangements according to the magnitude of the net
magnetic field at the dot, midway between the loops on the central axis, greatest first.

![Figure 29-23](image)

**Proof of Equation 29-26**

Figure 29-23 shows the back half of a circular loop of radius \( R \) carrying a current
\( i \). Consider a point \( P \) on the central axis of the loop, a distance \( z \) from its plane.
Let us apply the law of Biot and Savart to a differential element \( ds \) of the loop,
located at the left side of the loop. The length vector \( ds' \) for this element points
perpendicularly out of the page. The angle \( \theta \) between \( ds' \) and \( \hat{r} \) in Fig. 29-23 is 90°;
the plane formed by these two vectors is perpendicular to the plane of the page
and contains both \( \hat{r} \) and \( ds' \). From the law of Biot and Savart (and the right-hand
rule), the differential field \( dB \) produced at point \( P \) by the current in this element
is perpendicular to this plane and thus is directed in the plane of the figure,
perpendicular to \( \hat{r} \), as indicated in Fig. 29-23.

Let us resolve \( dB \) into two components: \( dB_\parallel \) along the axis of the loop
and \( dB_\perp \) perpendicular to this axis. From the symmetry, the vector sum of all the per-
pendicular components \( dB_\perp \) due to all the loop elements \( ds \) is zero. This leaves
only the axial (parallel) components \( dB_\parallel \) and we have

\[
B = \int dB_\parallel.
\]

For the element \( ds' \) in Fig. 29-23, the law of Biot and Savart (Eq. 29-1) tells us
that the magnetic field at distance \( r \) is

\[
dB = \frac{\mu_0 i ds \sin 90^\circ}{4\pi r^2}.
\]

We also have

\[
dB_\parallel = dB \cos \alpha.
\]

Combining these two relations, we obtain

\[
dB_\parallel = \frac{\mu_0 i \cos \alpha ds}{4\pi r^2}.
\] (29-28)

Figure 29-23 shows that \( r \) and \( \alpha \) are related to each other. Let us express each in
terms of the variable \( z \), the distance between point \( P \) and the center of the loop.
The relations are

\[
r = \sqrt{R^2 + z^2}
\] (29-29)
and \[ \cos \alpha = \frac{R}{r} = \frac{R}{\sqrt{R^2 + z^2}}. \quad (29-30) \]

Substituting Eqs. 29-29 and 29-30 into Eq. 29-28, we find
\[ dB = \frac{\mu_0 i R}{4\pi (R^2 + z^2)^{3/2}} \, ds. \]
Note that \( i, R, \) and \( z \) have the same values for all elements \( ds \) around the loop; so when we integrate this equation, we find that
\[ B = \int dB = \frac{\mu_0 i R}{4\pi (R^2 + z^2)^{3/2}} \int ds \]
or, because \( \int ds \) is simply the circumference \( 2\pi R \) of the loop,
\[ B(z) = \frac{\mu_0 i R^2}{2(R^2 + z^2)^{3/2}}. \]
This is Eq. 29-26, the relation we sought to prove.

**Review & Summary**

**The Biot–Savart Law**  The magnetic field set up by a current-carrying conductor can be found from the Biot–Savart law. This law asserts that the contribution \( d\vec{B} \) to the field produced by a current-length element \( i \, ds \) at a point \( P \) located a distance \( r \) from the current element is
\[ d\vec{B} = \frac{\mu_0 i \hat{r} \times \vec{r}}{4\pi r^2} \]  \( \text{(Biot–Savart law).} \quad (29-3) \]
Here \( \hat{r} \) is a unit vector that points from the element toward \( P \). The quantity \( \mu_0 \), called the permeability constant, has the value
\[ 4\pi \times 10^{-7} \, \text{T} \cdot \text{m/A} \approx 1.26 \times 10^{-6} \, \text{T} \cdot \text{m/A}. \]

**Magnetic Field of a Long Straight Wire**  For a long straight wire carrying a current \( i \), the Biot–Savart law gives, for the magnitude of the magnetic field at a perpendicular distance \( R \) from the wire,
\[ B = \frac{\mu_0 i}{2\pi R} \]  \( \text{(long straight wire).} \quad (29-4) \]

**Magnetic Field of a Circular Arc**  The magnitude of the magnetic field at the center of a circular arc, of radius \( R \) and central angle \( \phi \) (in radians), carrying current \( i \), is
\[ B = \frac{\mu_0 i \phi}{4\pi R} \]  \( \text{(at center of circular arc).} \quad (29-9) \]

**Force Between Parallel Currents**  Parallel wires carrying currents in the same direction attract each other, whereas parallel wires carrying currents in opposite directions repel each other. The magnitude of the force on a length \( L \) of either wire is
\[ F_{ba} = i_b L B_a \sin 90^\circ = \frac{\mu_0 i_a i_b}{2\pi d}, \]  \( \text{(29-13)} \)
where \( d \) is the wire separation, and \( i_a \) and \( i_b \) are the currents in the wires.

**Ampere's Law**  **Ampere’s law** states that
\[ \oint \vec{B} \cdot d\vec{s} = \mu_0 i_{\text{enc}} \]  \( \text{(Ampere’s law).} \quad (29-14) \]
The line integral in this equation is evaluated around a closed loop called an Amperian loop. The current \( i \) on the right side is the net current encircled by the loop. For some current distributions, Eq. 29-14 is easier to use than Eq. 29-3 to calculate the magnetic field due to the currents.

**Fields of a Solenoid and a Toroid**  Inside a long solenoid carrying current \( i \), at points not near its ends, the magnitude \( B \) of the magnetic field is
\[ B = \mu_0 \mu_i n \]  \( \text{(ideal solenoid),} \quad (29-23) \)
where \( n \) is the number of turns per unit length. Thus the internal magnetic field is uniform. Outside the solenoid, the magnetic field is approximately zero.

At a point inside a toroid, the magnitude \( B \) of the magnetic field is
\[ B = \frac{\mu_0 i N}{2\pi r} \]  \( \text{(toroid),} \quad (29-24) \)
where \( r \) is the distance from the center of the toroid to the point.

**Field of a Magnetic Dipole**  The magnetic field produced by a current-carrying coil, which is a magnetic dipole, at a point \( P \) located a distance \( z \) along the coil’s perpendicular central axis is parallel to the axis and is given by
\[ \vec{B}(z) = \frac{\mu_0 \vec{\mu}}{2\pi z^3}, \]  \( \text{(29-27)} \)
where \( \vec{\mu} \) is the dipole moment of the coil. This equation applies only when \( z \) is much greater than the dimensions of the coil.
1. Figure 29-24 shows three circuits, each consisting of two radial lengths and two concentric circular arcs, one of radius \( r \) and the other of radius \( R > r \). The circuits have the same current through them and the same angle between the two radial lengths. Rank the circuits according to the magnitude of the net magnetic field at the center, greatest first.

![Figure 29-24](image)

**Figure 29-24** Question 1.

2. Figure 29-25 represents a snapshot of the velocity vectors of four electrons near a wire carrying current \( i \). The four velocities have the same magnitude; velocity \( \vec{v}_2 \) is directed into the page. Electrons 1 and 2 are at the same distance from the wire, as are electrons 3 and 4. Rank the electrons according to the magnitudes of the magnetic forces on them due to current \( i \), greatest first.

![Figure 29-25](image)

**Figure 29-25** Question 2.

3. Figure 29-26 shows four arrangements in which long parallel wires carry equal currents directly into or out of the page at the corners of identical squares. Rank the arrangements according to the magnitude of the net magnetic field at the center of the square, greatest first.

![Figure 29-26](image)

**Figure 29-26** Question 3.

4. Figure 29-27 shows cross sections of two long straight wires; the left-hand wire carries current \( i_1 \) directly out of the page. If the net magnetic field due to the two currents is to be zero at point \( P \), (a) should the direction of current \( i_2 \) in the right-hand wire be directly into or out of the page and (b) should \( i_2 \) be greater than, less than, or equal to \( i_1 \)?

![Figure 29-27](image)

**Figure 29-27** Question 4.

5. Figure 29-28 shows three circuits consisting of straight radial lengths and concentric circular arcs (either half- or quarter-circles of radii \( r, 2r, \) and \( 3r \)). The circuits carry the same current. Rank them according to the magnitude of the magnetic field produced at the center of curvature (the dot), greatest first.

![Figure 29-28](image)

**Figure 29-28** Question 5.

6. Figure 29-29 gives, as a function of radial distance \( r \), the magnitude \( B \) of the magnetic field inside and outside four wires (a, b, c, and d), each of which carries a current that is uniformly distributed across the wire’s cross section. Overlapping portions of the plots (drawn slightly separated) are indicated by double labels. Rank the wires according to (a) radius, (b) the magnitude of the magnetic field on the surface, and (c) the value of the current, greatest first. (d) Is the magnitude of the current density in wire a greater than, less than, or equal to that in wire c?

![Figure 29-29](image)

**Figure 29-29** Question 6.

7. Figure 29-30 shows four circular Amperian loops (a, b, c, d) concentric with a wire whose current is directed out of the page. The current is uniform across the wire’s circular cross section (the shaded region). Rank the loops according to the magnitude of \( \oint B \cdot ds \) around each, greatest first.

![Figure 29-30](image)

**Figure 29-30** Question 7.

8. Figure 29-31 shows four arrangements in which long, parallel, equally spaced wires carry equal currents directly into or out of the page. Rank the arrangements according to the magnitude of the net force on the central wire due to the currents in the other wires, greatest first.

![Figure 29-31](image)

**Figure 29-31** Question 8.

9. Figure 29-32 shows four circular Amperian loops (a, b, c, d) and, in cross section, four long circular conductors (the shaded regions), all of which are concentric. Three of the conductors are hollow cylinders; the central conductor is a solid cylinder. The currents in the conductors are, from smallest radius to largest radius, 4 A out of...
the page, 9 A into the page, 5 A out of the page, and 3 A into the page. Rank the Amperian loops according to the magnitude of \( \oint B \cdot ds \) around each, greatest first.

10 Figure 29-33 shows four identical currents \( i \) and five Amperian paths (a through e) encircling them. Rank the paths according to the value of \( \oint B \cdot ds \) taken in the directions shown, most positive first.

Figure 29-33 Question 10.

11 Figure 29-34 shows three arrangements of three long straight wires carrying equal currents directly into or out of the page. (a) Rank the arrangements according to the magnitude of the net force on wire \( A \) due to the currents in the other wires, greatest first. (b) In arrangement 3, is the angle between the net force on wire \( A \) and the dashed line equal to, less than, or more than 45°?

Figure 29-34 Question 11.

Module 29-1 Magnetic Field Due to a Current

1 A surveyor is using a magnetic compass 6.1 m below a power line in which there is a steady current of 100 A. (a) What is the magnetic field at the site of the compass due to the power line? (b) Will this field interfere seriously with the compass reading? The horizontal component of Earth’s magnetic field at the site is 20 \( \mu \)T.

2 Figure 29-35a shows an element of length \( ds = 1.00 \mu \text{m} \) in a very long straight wire carrying current. The current in that element sets up a differential magnetic field \( dB \) at points in the surrounding space. Figure 29-35b gives the magnitude \( dB \) of the field for points 2.5 cm from the element, as a function of angle \( \theta \) between the wire and a straight line to the point. The vertical scale is set by \( dB_s = 60.0 \) pT. What is the magnitude of the magnetic field set up by the entire wire at perpendicular distance 2.5 cm from the wire?

3 At a certain location in the Philippines, Earth’s magnetic field of 39 \( \mu \)T is horizontal and directed due north. Suppose the net field is zero exactly 8.0 cm above a long, straight, horizontal wire that carries a constant current. What are the (a) magnitude and (b) direction of the current?

4 A straight conductor carrying current \( i = 5.0 \) A splits into identical semicircular arcs as shown in Fig. 29-36. What is the magnetic field at the center \( C \) of the resulting circular loop?

5 In Fig. 29-37, a current \( i = 10 \) A is set up in a long hairpin conductor formed by bending a wire into a semicircle of radius \( R = 5.0 \) mm. Point \( b \) is midway between the straight sections and so distant from the semicircle that each straight section can be approximated as being an infinite wire. What are the (a) magnitude and (b) direction (into or out of the page) of \( B \) at \( a \) and the (c) magnitude and (d) direction of \( B \) at \( b \)?

6 In Fig. 29-38, point \( P \) is at perpendicular distance \( R = 2.00 \) cm from a very long straight wire carrying a current. The magnetic field \( B \) set up at point \( P \) is due to contributions from all the identical current-length elements \( i \ ds \) along the wire. What is the distance \( s \) to the
element making (a) the greatest contribution to field \( \vec{B} \) and (b) 10.0% of the greatest contribution?

**7** In Fig. 29-39, two circular arcs have radii \( a = 13.5 \text{ cm} \) and \( b = 10.7 \text{ cm} \), subtend angle \( \theta = 74.0^\circ \), carry current \( i = 0.411 \text{ A} \), and share the same center of curvature \( P \). What are the (a) magnitude and (b) direction (into or out of the page) of the net magnetic field at \( P \)?

**8** In Fig. 29-40, two semicircular arcs have radii \( R_0 = 7.80 \text{ cm} \) and \( R_1 = 3.15 \text{ cm} \), carry current \( i = 0.281 \text{ A} \), and have the same center of curvature \( C \). What are the (a) magnitude and (b) direction (into or out of the page) of the net magnetic field at \( C \)?

**9** SSM Two long straight wires are parallel and 8.0 cm apart. They are to carry equal currents such that the magnetic field at a point halfway between them has magnitude 300 \( \mu \text{T} \). (a) Should the currents be in the same or opposite directions? (b) How much current is needed?

**10** In Fig. 29-41, a wire forms a semicircle of radius \( R = 9.26 \text{ cm} \) and two (radial) straight segments each of length \( L = 13.1 \text{ cm} \). The wire carries current \( i = 34.8 \text{ mA} \). What are the (a) magnitude and (b) direction (into or out of the page) of the net magnetic field at the semicircle’s center of curvature \( C \)?

**11** In Fig. 29-42, two long straight wires are perpendicular to the page and separated by distance \( d_1 = 0.75 \text{ cm} \). Wire 1 carries 6.5 A into the page. What are the (a) magnitude and (b) direction (into or out of the page) of the current in wire 2 if the net magnetic field due to the two currents is zero at point \( P \) located at distance \( d_2 = 1.50 \text{ cm} \) from wire 2?

**12** In Fig. 29-43, two long straight wires at separation \( d = 16.0 \text{ cm} \) carry currents \( i_1 = 3.61 \text{ mA} \) and \( i_2 = 3.00i_1 \) out of the page. (a) Where on the \( x \) axis is the net magnetic field equal to zero? (b) If the two currents are doubled, is the zero-field point shifted toward wire 1, shifted toward wire 2, or unchanged?

**13** In Fig. 29-44, point \( P_1 \) is at distance \( R = 13.1 \text{ cm} \) on the perpendicular bisector of a straight wire of length \( L = 18.0 \text{ cm} \) carrying current \( i = 58.2 \text{ mA} \). (Note that the wire is not long.) What is the magnitude of the magnetic field at \( P_1 \) due to it?

**14** Equation 29-4 gives the magnitude \( B \) of the magnetic field set up by a current in an infinitely long straight wire, at a point \( P \) at perpendicular distance \( R \) from the wire. Suppose that point \( P \) is actually at perpendicular distance \( R \) from the midpoint of a wire with a finite length \( L \). Using Eq. 29-4 to calculate \( B \) then results in a certain percentage error. What value must the ratio \( L/R \) exceed if the percentage error is to be less than 1.00%? That is, what \( L/R \) gives

\[
\frac{(B \text{ from Eq. 29-4}) - (B \text{ actual})}{(B \text{ actual})} (100\%) = 1.00\%?
\]

**15** Figure 29-45 shows two current segments. The lower segment carries a current of \( i_1 = 0.40 \text{ A} \) and includes a semicircular arc with radius 5.0 cm, angle 180°, and center point \( P \). The upper segment carries current \( i_2 = 2i_1 \) and includes a circular arc with radius 4.0 cm, angle 120°, and the same center point \( P \). What are the (a) magnitude and (b) direction of the net magnetic field \( \vec{B} \) at \( P \) for the indicated current directions? What are the (c) magnitude and (d) direction of \( \vec{B} \) if \( i_1 \) is reversed?

**16** SSM In Fig. 29-46, two concentric circular loops of wire carrying current in the same direction lie in the same plane. Loop 1 has radius 1.50 cm and carries 4.00 mA. Loop 2 has radius 2.50 cm and carries 6.00 mA. Loop 2 is to be rotated about a diameter while the net magnetic field \( \vec{B} \) set up by the two loops at their common center is measured. Through what angle must loop 2 be rotated so that the magnitude of that net field is 100 \( \mu \text{T} \)?

**17** SSM In Fig. 29-44, point \( P_2 \) is at perpendicular distance \( R = 25.1 \text{ cm} \) from one end of a straight wire of length \( L = 13.6 \text{ cm} \) carrying current \( i = 0.693 \text{ A} \). (Note that the wire is not long.) What is the magnitude of the magnetic field at \( P_2 \)?

**18** A current is set up in a wire loop consisting of a semicircle of radius 4.00 cm, a smaller concentric semicircle, and two radial straight lengths, all in the same plane. Figure 29-47a shows the arrangement but is not drawn to scale. The magnitude of the magnetic field produced at the center of curvature is 47.25 \( \mu \text{T} \). The smaller semicircle is then flipped over (rotated) until the loop is again entirely in the same plane (Fig. 29-47b). The magnetic field produced at the (same) center of curvature now has magnitude 15.75 \( \mu \text{T} \), and its direction is reversed from the initial magnetic field. What is the radius of the smaller semicircle?

**19** One long wire lies along an \( x \) axis and carries a current of 30 A in the positive \( x \) direction. A second long wire is perpendicular to the \( xy \) plane, passes through the point \((0, 4.0 \text{ m}, 0)\), and carries a current of 40 A in the positive \( z \) direction. What is the magnitude of the resulting magnetic field at the point \((0, 2.0 \text{ m}, 0)\)?
In Fig. 29-48, part of a long insulated wire carrying current $i = 5.78 \text{ mA}$ is bent into a circular section of radius $R = 1.89 \text{ cm}$. In unit-vector notation, what is the magnitude of the magnetic field at the center of curvature $C$ if the circular section (a) lies in the plane of the page as shown and (b) is perpendicular to the plane of the page after being rotated 90° counterclockwise as indicated?

Figure 29-49 shows two very long straight wires (in cross section) that each carry a current of 4.00 A directly out of the page. Distance $d_1 = 6.00 \text{ m}$ and distance $d_2 = 4.00 \text{ m}$. What is the magnitude of the net magnetic field at point $P$, which lies on a perpendicular bisector to the wires?

Figure 29-50a shows, in cross section, two long, parallel wires carrying current and separated by distance $L$. The ratio $i_1/i_2$ of their currents is 4.00; the directions of the currents are not indicated. Figure 29-50b shows the $y$ component $B_y$ of their net magnetic field along the $x$ axis to the right of wire 2. The vertical scale is set by $B_y = 4.0 \text{ nT}$, and the horizontal scale is set by $x_y = 20.0 \text{ cm}$. (a) At what value of $x > 0$ is $B_y$ maximum? (b) If $i_2 = 3 \text{ mA}$, what is the value of that maximum? What is the direction (into or out of the page) of (c) $i_1$ and (d) $i_2$?

Figure 29-51 shows a snapshot of a proton moving at velocity $\vec{v} = (-200 \text{ m/s})\hat{j}$ toward a long straight wire with current $i = 350 \text{ mA}$. At the instant shown, the proton’s distance from the wire is $d = 2.89 \text{ cm}$. In unit-vector notation, what is the magnetic force on the proton due to the current?

Figure 29-52 shows, in cross section, four thin wires that are parallel, straight, and very long. They carry identical currents in the directions indicated. Initially all four wires are at distance $d = 15.0 \text{ cm}$ from the origin of the coordinate system, where they create a net magnetic field $\vec{B}$. (a) To what value of $x$ must you move wire 3 along the $x$ axis to rotate $\vec{B}$ by 30° back to its initial orientation? (b) With wire 1 in that new position, to what value of $x$ must you move wire 2 along the $x$ axis to rotate $\vec{B}$ by 30° back to its initial orientation?

In Fig. 29-53, two semi-infinite straight sections, both tangent to the same circle, are connected by a circular arc that has a central angle $\theta$ and runs along the circumference of the circle. The arc and the two straight sections all lie in the same plane. If $\vec{B} = 0$ at the circle’s center, what is $\theta$?

In Fig. 29-54a, wire 1 consists of a circular arc and two radial lengths; it carries current $i_1 = 0.50 \text{ A}$ in the direction indicated. Wire 2, shown in cross section, is long, straight, and perpendicular to the plane of the figure. Its distance from the center of the arc is equal to the radius $R$ of the arc, and it carries a current $i_2$ that can be varied. The two currents set up a net magnetic field $\vec{B}$ at the center of the arc. Figure 29-54b gives the square of the field’s magnitude $B^2$ plotted versus the square of the current $i_2^2$. The vertical scale is set by $B_0^2 = 10.0 \times 10^{-10} \text{T}^2$. What angle is subtended by the arc?

In Fig. 29-55, two long straight wires (shown in cross section) carry the currents $i_1 = 30.0 \text{ mA}$ and $i_2 = 40.0 \text{ mA}$ directly out of the page. They are equal distances from the origin, where they set up a magnetic field $\vec{B}$. To what value must current $i_1$ be changed in order to rotate $\vec{B}$ 20.0° clockwise?

Figure 29-56a shows two wires, each carrying a current. Wire 1 consists of a circular arc of radius $R = 1.89 \text{ cm}$ and carries a current $i_1 = 2.89 \text{ mA}$ directly out of the page. Wire 2, shown in cross section, is long, straight, and perpendicular to the plane of the figure. Its distance from the center of the arc is equal to the radius $R$ of the arc, and it carries a current $i_2$ that can be varied. The two currents set up a net magnetic field $\vec{B}$ at the center of the arc. Figure 29-56b gives the magnitude of the field $B^2$ plotted versus the square of the current $i_2^2$. The vertical scale is set by $B_0^2 = 10.0 \times 10^{-8} \text{T}^2$. What angle is subtended by the arc?
radius $R$ and two radial lengths; it carries current $i_1 = 2.0$ A in the direction indicated. Wire 2 is long and straight; it carries a current $i_2$ that can be varied; and it is at distance $R/2$ from the center of the arc. The net magnetic field $\mathbf{B}$ due to the two currents is measured at the center of curvature of the arc. Figure 29-56b is a plot of the component of $\mathbf{B}$ in the direction perpendicular to the figure as a function of current $i_2$. The horizontal scale is set by $i_{20} = 1.00$ A. What is the angle subtended by the arc?

**29 SSM** In Fig. 29-57, four straight wires are perpendicular to the page, and their cross sections form a square of edge length $a = 20$ cm. The currents are out of the page in wires 1 and 4 and into the page in wires 2 and 3, and each wire carries 20 A. In unit-vector notation, what is the net magnetic field at the square’s center?

![Figure 29-57](image)

**30** Two long thin wires with current lie against an equally long plastic cylinder, at radius $R = 20.0$ cm from the cylinder’s central axis. Figure 29-58a shows, in cross section, the cylinder and wire 1 but not wire 2. With wire 2 fixed in place, wire 1 is moved around the cylinder, from angle $\theta_1 = 0^\circ$ to angle $\theta_1 = 180^\circ$, through the first and second quadrants of the $xy$ coordinate system. The net magnetic field $\mathbf{B}$ at the center of the cylinder is measured as a function of $\theta_1$. Figure 29-58b gives the $x$ component $B_x$ of that field as a function of $\theta_1$ (the vertical scale is set by $B_{xi} = 6.0$ $\mu$T), and Fig. 29-58c gives the $y$ component $B_y$ (the vertical scale is set by $B_{yi} = 4.0$ $\mu$T). (a) At what angle $\theta_1$ is wire 2 located? What are the (b) size and (c) direction (into or out of the page) of the current in wire 1 and the (d) size and (e) direction of the current in wire 2?

![Figure 29-58](image)

**31** In Fig. 29-59, length $a$ is 4.7 cm (short) and current $i$ is 13 A. What are the (a) magnitude and (b) direction (into or out of the page) of the magnetic field at point $P$?

![Figure 29-59](image)

**32** The current-carrying wire loop in Fig. 29-60a lies all in one plane and consists of a semicircle of radius 10.0 cm, a smaller semicircle with the same center, and two radial lengths. The smaller semicircle is rotated out of that plane by angle $\theta$, until it is perpendicular to the plane (Fig. 29-60b). Figure 29-60c gives the magnitude of the net magnetic field at the center of curvature versus angle $\theta$. The vertical scale is set by $B_\theta = 10.0$ $\mu$T and $B_\phi = 12.0$ $\mu$T. What is the radius of the smaller semicircle?

![Figure 29-60](image)

**33 SSM ILW** Figure 29-61 shows a cross section of a long thin ribbon of width $w = 4.91$ cm that is carrying a uniformly distributed total current $i = 4.61$ mA into the page. In unit-vector notation, what is the magnetic field $\mathbf{B}$ at a point $P$ in the plane of the ribbon at a distance $d = 2.16$ cm from its edge? (Hint: Imagine the ribbon as being constructed from many long, thin, parallel wires.)

![Figure 29-61](image)

**34** Figure 29-62 shows, in cross section, two long straight wires held against a plastic cylinder of radius 20.0 cm. Wire 1 carries current $i_1 = 60.0$ mA out of the page and is fixed in place at the left side of the cylinder. Wire 2 carries current $i_2 = 40.0$ mA out of the page and can be moved around the cylinder. At what (positive) angle $\theta_2$ should wire 2 be positioned such that, at the origin, the net magnetic field due to the two currents has magnitude 80.0 nT?

**Module 29-2 Force Between Two Parallel Currents**

**35 SSM** Figure 29-63 shows wire 1 in cross section; the wire is long
and straight, carries a current of 4.00 mA out of the page, and is at distance \( d_1 = 2.40 \text{ cm} \) from a surface. Wire 2, which is parallel to wire 1 and also long, is at horizontal distance \( d_2 = 5.00 \text{ cm} \) from wire 1 and carries a current of 6.80 mA into the page. What is the \( x \) component of the magnetic force per unit length on wire 2 due to wire 1?

**36** In Fig. 29-64, five long parallel wires in an \( xy \) plane are separated by distance \( d = 8.00 \text{ cm} \), have lengths of 10.0 m, and carry identical currents of 3.00 A out of the page. Each wire experiences a magnetic force due to the currents in the other wires. In unit-vector notation, what is the net magnetic force on (a) wire 1, (b) wire 2, (c) wire 3, (d) wire 4, and (e) wire 5?

**37** In Fig. 29-57, four long straight wires are perpendicular to the page, and their cross sections form a square of edge length \( a = 13.5 \text{ cm} \). Each wire carries 7.50 A, and the currents are out of the page in wires 1 and 4 and into the page in wires 2 and 3. In unit-vector notation, what is the net magnetic force per meter of wire length on wire 4?

**38** Figure 29-65a shows, in cross section, three current-carrying wires that are long, straight, and parallel to one another. Wires 1 and 2 are fixed in place on an \( x \) axis, with separation \( d \). Wire 1 has a current of 0.750 A, but the direction of the current is not given. Wire 3, with a current of 0.250 A out of the page, can be moved along the \( x \) axis to the right of wire 2. As wire 3 is moved, the magnitude of the magnetic force \( F_y \) on wire 2 due to the currents in wires 1 and 3 changes. The \( x \) component of force is \( F_x \), and the value per unit length of wire 2 is \( F_x/L_2 \). Figure 29-65b gives \( F_x/L_2 \) versus the position \( x \) of wire 3. The plot has an asymptote \( F_x/L_2 = -0.627 \mu \text{N/m} \) as \( x \to \infty \). The horizontal scale is set by \( x_1 = 12.0 \text{ cm} \). What are the (a) size and (b) direction (into or out of the page) of the current in wire 2?

**39** In Fig. 29-64, five long parallel wires in an \( xy \) plane are separated by distance \( d = 50.0 \text{ cm} \). The currents into the page are \( i_1 = 2.00 \text{ A} \), \( i_2 = 0.250 \text{ A} \), \( i_3 = 4.00 \text{ A} \), and \( i_4 = 2.00 \text{ A} \); the current out of the page is \( i_5 = 4.00 \text{ A} \). What is the magnitude of the net force per unit length acting on wire 3 due to the currents in the other wires?

**40** In Fig. 29-57, four long straight wires are perpendicular to the page, and their cross sections form a square of edge length \( a = 8.50 \text{ cm} \). Each wire carries 15.0 A, and all the currents are out of the page. In unit-vector notation, what is the net magnetic force per meter of wire length on wire 1?

**41** In Fig. 29-66, a long straight wire carries a current \( i_1 = 30.0 \text{ A} \) and a rectangular loop carries current \( i_2 = 20.0 \text{ A} \). Take the dimensions to be \( a = 1.00 \text{ cm} \), \( b = 8.00 \text{ cm} \), and \( L = 30.0 \text{ cm} \). In unit-vector notation, what is the net force on the loop due to \( i_1 \)?

**Ampere’s Law**

**42** In a particular region there is a uniform current density of 15 A/m\(^2\) in the positive \( z \) direction. What is the value of \( \oint \mathbf{B} \cdot d\mathbf{s} \) when that line integral is calculated along a closed path consisting of the three straight-line segments from \((x, y, z)\) coordinates \((4d, 0, 0)\) to \((4d, 3d, 0)\) to \((0, 0, 0)\) to \((4d, 0, 0)\), where \( d = 20 \text{ cm} \)?

**43** Figure 29-67 shows a cross section of a long cylindrical conductor of radius \( a = 2.00 \text{ cm} \) carrying uniform current \( 170 \text{ A} \). What is the magnitude of the current’s magnetic field at radial distance \( a \), \( b = 1.00 \text{ cm} \), \( c = 2.00 \text{ cm} \) (wire’s surface), and \( d = 4.00 \text{ cm} \)\(?

**44** Figure 29-68 shows two closed paths wrapped around two conducting loops carrying currents \( i_1 = 5.0 \text{ A} \) and \( i_2 = 3.0 \text{ A} \). What is the value of the integral \( \oint \mathbf{B} \cdot d\mathbf{s} \) for (a) path 1 and (b) path 2?

**45** Each of the eight conductors in Fig. 29-69 carries 2.0 A of current into or out of the page. Two paths are indicated for the line integral \( \oint \mathbf{B} \cdot d\mathbf{s} \). What is the value of the integral for (a) path 1 and (b) path 2?

**46** Eight wires cut the page perpendicularly at the points shown in Fig. 29-70. A wire labeled with the integer \( k \) (\( k = 1, 2, \ldots, 8 \)) carries the current \( ki \), where \( i = 4.50 \text{ mA} \). For those wires with odd \( k \), the current is out of the page; for those with even \( k \), it is into the page. Evaluate \( \oint \mathbf{B} \cdot d\mathbf{s} \) along the closed path indicated and in the direction shown.

**47** In Fig. 29-69, a long straight wire carries a current \( i_1 = 30.0 \text{ A} \) and a rectangular loop carries current \( i_2 = 20.0 \text{ A} \). Take the dimensions to be \( a = 1.00 \text{ cm} \), \( b = 8.00 \text{ cm} \), and \( L = 30.0 \text{ cm} \). In unit-vector notation, what is the net force on the loop due to \( i_1 \)?

**Module 29-3**

**42** In a particular region there is a uniform current density of 15 A/m\(^2\) in the positive \( z \) direction. What is the value of \( \oint \mathbf{B} \cdot d\mathbf{s} \) when that line integral is calculated along a closed path consisting of the three straight-line segments from \((x, y, z)\) coordinates \((4d, 0, 0)\) to \((4d, 3d, 0)\) to \((0, 0, 0)\) to \((4d, 0, 0)\), where \( d = 20 \text{ cm} \)?

**43** Figure 29-67 shows a cross section of a long cylindrical conductor of radius \( a = 2.00 \text{ cm} \) carrying uniform current \( 170 \text{ A} \). What is the magnitude of the current’s magnetic field at radial distance \( a \), \( b = 1.00 \text{ cm} \), \( c = 2.00 \text{ cm} \) (wire’s surface), and \( d = 4.00 \text{ cm} \)\(?

**44** Figure 29-68 shows two closed paths wrapped around two conducting loops carrying currents \( i_1 = 5.0 \text{ A} \) and \( i_2 = 3.0 \text{ A} \). What is the value of the integral \( \oint \mathbf{B} \cdot d\mathbf{s} \) for (a) path 1 and (b) path 2?

**45** Each of the eight conductors in Fig. 29-69 carries 2.0 A of current into or out of the page. Two paths are indicated for the line integral \( \oint \mathbf{B} \cdot d\mathbf{s} \). What is the value of the integral for (a) path 1 and (b) path 2?

**46** Eight wires cut the page perpendicularly at the points shown in Fig. 29-70. A wire labeled with the integer \( k \) (\( k = 1, 2, \ldots, 8 \)) carries the current \( ki \), where \( i = 4.50 \text{ mA} \). For those wires with odd \( k \), the current is out of the page; for those with even \( k \), it is into the page. Evaluate \( \oint \mathbf{B} \cdot d\mathbf{s} \) along the closed path indicated and in the direction shown.

**47** In Fig. 29-69, a long straight wire carries a current \( i_1 = 30.0 \text{ A} \) and a rectangular loop carries current \( i_2 = 20.0 \text{ A} \). Take the dimensions to be \( a = 1.00 \text{ cm} \), \( b = 8.00 \text{ cm} \), and \( L = 30.0 \text{ cm} \). In unit-vector notation, what is the net force on the loop due to \( i_1 \)?
310 A/m². Find the magnitude of the magnetic field at (a) \( r = 0 \), (b) \( r = a/2 \), and (c) \( r = a \).

48 In Fig. 29-71, a long circular pipe with outside radius \( R = 2.6 \) cm carries a (uniformly distributed) current \( i = 8.00 \) mA into the page. A wire runs parallel to the pipe at a distance of 3.00 \( R \) from center to center. Find the (a) magnitude and (b) direction (into or out of the page) of the current in the wire such that the net magnetic field at point \( P \) has the same magnitude as the net magnetic field at the center of the pipe but is in the opposite direction.

**Module 29-4 Solenoids and Toroids**

49 A toroid having a square cross section, 5.00 cm on a side, and an inner radius of 15.0 cm has 500 turns and carries a current of 0.800 A. (It is made up of a square solenoid—instead of a round one as in Fig. 29-17—bent into a doughnut shape.) What is the magnetic field inside the toroid at (a) the inner radius and (b) the outer radius?

50 A solenoid that is 95.0 cm long has a radius of 2.00 cm and a winding of 1200 turns; it carries a current of 3.60 A. Calculate the magnitude of the magnetic field inside the solenoid.

51 A 200-turn solenoid having a length of 25 cm and a diameter of 10 cm carries a current of 0.29 A. Calculate the magnitude of the magnetic field inside the solenoid.

52 A solenoid 1.30 m long and 2.60 cm in diameter carries a current of 18.0 A. The magnetic field inside the solenoid is 23.0 mT. Find the length of the wire forming the solenoid.

53 A long solenoid has 100 turns/cm and carries current \( i \). An electron moves within the solenoid in a circle of radius 2.30 cm perpendicular to the solenoid axis. The speed of the electron is 0.0460c (\( c = \) speed of light). Find the current \( i \) in the solenoid.

54 An electron is shot into one end of a solenoid. As it enters the uniform magnetic field within the solenoid, its speed is 800 m/s and its velocity vector makes an angle of 30° with the central axis of the solenoid. The solenoid carries 4.0 A and has 8000 turns along its length. How many revolutions does the electron make along its helical path within the solenoid by the time it emerges from the solenoid’s opposite end? (In a real solenoid, where the field is not uniform at the two ends, the number of revolutions would be slightly less than the answer here.)

55 SSM ILW WWW A long solenoid with 10.0 turns/cm and a radius of 7.00 cm carries a current of 20.0 mA. A current of 6.00 A exists in a straight conductor located along the central axis of the solenoid. (a) At what radial distance from the axis will the direction of the resulting magnetic field be at 45.0° to the axial direction? (b) What is the magnitude of the magnetic field there?

**Module 29-5 A Current-Carrying Coil as a Magnetic Dipole**

56 Figure 29-72 shows an arrangement known as a Helmholtz coil. It consists of two circular coaxial coils, each of 200 turns and radius \( R = 25.0 \) cm, separated by a distance \( r = R \). The two coils carry equal currents \( i = 12.2 \) mA in the same direction. Find the magnitude of the net magnetic field at \( P \), midway between the coils.

57 SSM A student makes a short electromagnet by winding 300 turns of wire around a wooden cylinder of diameter \( d = 5.0 \) cm. The coil is connected to a battery producing a current of 4.0 A in the wire. (a) What is the magnitude of the magnetic dipole moment of this device? (b) At what axial distance \( z \gg d \) will the magnetic field have the magnitude 5.0 \( \mu \)T (approximately one-tenth that of Earth’s magnetic field)?

58 Figure 29-73a shows a length of wire carrying a current \( i \) and bent into a circular coil of one turn. In Fig. 29-73b the same length of wire has been bent to give a coil of two turns, each of half the original radius. (a) If \( B_a \) and \( B_b \) are the magnitudes of the magnetic fields at the centers of the two coils, what is the ratio \( B_b/B_a^2 \)? (b) What is the ratio \( \mu_b/\mu_a \) of the dipole moment magnitudes of the coils?

59 SSM What is the magnitude of the magnetic dipole moment \( \mu \) of the solenoid described in Problem 51?

60 SSM In Fig. 29-74a, two circular loops, with different currents but the same radius of 4.0 cm, are centered on a y axis. They are initially separated by distance \( L = 3.0 \) cm, with loop 2 positioned at the origin of the axis. The currents in the two loops produce a net magnetic field at the origin, with y component \( B_y \). That component is to be measured as loop 2 is gradually moved in the positive direction of the y axis. Figure 29-74b gives \( B_y \) as a function of the position \( y \) of loop 2. The curve approaches an asymptote of \( B_y = 7.20 \mu \)T as \( y \to \infty \). The horizontal scale is set by \( y_s = 10.0 \) cm. What are (a) current \( i_1 \) in loop 1 and (b) current \( i_2 \) in loop 2?

61 A circular loop of radius 12 cm carries a current of 15 A. A flat coil of radius 0.82 cm, having 50 turns and a current of 1.3 A, is concentric with the loop. The plane of the loop is perpendicular to the plane of the coil. Assume the loop’s magnetic field is uniform across the coil. What is the magnitude of (a) the magnetic field produced by the loop at its center and (b) the torque on the loop due to the loop?

62 In Fig. 29-75, current \( i = 56.2 \) mA is set up in a loop having two radial lengths and two semicircles...
icles of radii \(a = 5.72 \text{ cm}\) and \(b = 9.36 \text{ cm}\) with a common center \(P\). What are the (a) magnitude and (b) direction (into or out of the page) of the magnetic field at \(P\) and the (c) magnitude and (d) direction of the loop's magnetic dipole moment?

**63** In Fig. 29-76, a conductor carries 6.0 A along the closed path \(abcdefgaha\) running along 8 of the 12 edges of a cube of edge length 10 cm. (a) Taking the path to be a combination of three square current loops (\(bcfgb, abgfa\), and \(cdefc\)), find the net magnetic moment of the path in unit-vector notation. (b) What is the magnitude of the net magnetic field at the center of the wire is there a point within the wire where the curvature is zero, what are the \((a)\) magnitude and \((b)\) direction (into or out of the page) of the net magnetic field at the center of curvature? (c) If the current in wire 1 is reversed, at what value of \(y\) does \(B = 0\)? (d) If the current in wire 1 is reversed, at what value of \(y\) does \(B = 0\)?

**64** In Fig. 29-77, a closed loop carries current \(i = 200 \text{ mA}\). The loop consists of two radial straight wires and two concentric circular arcs of radii 2.00 m and 4.00 m. The angle \(\theta\) is \(\pi/4\) rad. What are the (a) magnitude and (b) direction (into or out of the page) of the net magnetic field at the center of curvature \(P\)?

**65** A cylindrical cable of radius 8.00 mm carries a current of 25.0 A, uniformly spread over its cross-sectional area. At what distance from the center of the wire is there a point within the wire where the magnetic field magnitude is 0.100 mT?

**66** Two long wires lie in an \(xy\) plane, and each carries a current in the positive direction of the \(x\) axis. Wire 1 is at \(y = 10.0 \text{ cm}\) and carries 6.00 A; wire 2 is at \(y = 5.00 \text{ cm}\) and carries 10.0 A. (a) In unit-vector notation, what is the net magnetic field \(\vec{B}\) at the origin? (b) At what value of \(y\) does \(B = 0\)? (c) If the current in wire 1 is reversed, at what value of \(y\) does \(B = 0\)?

**67** Two wires, both of length \(L\), are formed into a circle and a square, and each carries current \(i\). Show that the square produces a greater magnetic field at its center than the circle produces at its center.

**68** A long straight wire carries a current of 50 A. An electron, traveling at \(1.0 \times 10^7 \text{ m/s}\), is 5.0 cm from the wire. What is the magnitude of the magnetic force on the electron if the electron velocity is directed (a) toward the wire, (b) parallel to the wire in the direction of the current, and (c) perpendicular to the two directions defined by (a) and (b)?

**69** Three long wires are parallel to a \(z\) axis, and each carries a current of 10 A in the positive \(z\) direction. Their points of intersection with the \(xy\) plane form an equilateral triangle with sides of 50 cm, as shown in Fig. 29-78. A fourth wire (wire \(b\)) passes through the midpoint of the base of the triangle and is parallel to the other three wires. If the net magnetic force on wire \(a\) is zero, what are the (a) size and (b) direction (+ \(z\) or − \(z\)) of the current in wire \(b\)?

**70** Figure 29-79 shows a closed loop with current \(i = 2.00 \text{ A}\). The loop consists of a half-circle of radius 4.00 m, two quarter-circles each of radius 2.00 m, and three radial straight wires. What is the magnitude of the magnetic field at the common center of the circular sections?

**71** A 10-gauge bare copper wire (2.6 mm in diameter) can carry a current of 50 A without overheating. For this current, what is the magnitude of the magnetic field at the surface of the wire?

**72** A long vertical wire carries an unknown current. Coaxial with the wire is a long, thin, cylindrical conducting surface that carries a current of 30 mA upward. The cylindrical surface has a radius of 3.0 mm. If the magnitude of the magnetic field at a point 5.0 mm from the wire is 1.0 \(\mu\text{T}\), what are the (a) size and (b) direction of the current in the wire?

**73** Figure 29-80 shows a cross section of a long cylindrical conductor of radius \(a = 4.00 \text{ cm}\) containing a long cylindrical hole of radius \(b = 1.50 \text{ cm}\). The central axes of the cylinder and hole are parallel and are distance \(d = 2.00 \text{ cm}\) apart; current \(i = 5.25 \text{ A}\) is uniformly distributed over the tinted area. (a) What is the magnitude of the magnetic field at the center of the hole? (b) Discuss the two special cases \(b = 0\) and \(d = 0\).

**74** The magnitude of the magnetic field at a point 88.0 cm from the central axis of a long straight wire is 7.30 \(\mu\text{T}\). What is the current in the wire?

**75** Figure 29-81 shows a wire segment of length \(\Delta s = 3.00 \text{ cm}\), centered at the origin, carrying current \(i = 2.00 \text{ A}\) in the positive \(y\) direction (as part of some complete circuit). To calculate the magnitude of the magnetic field \(\vec{B}\) produced by the segment at a point several meters from the origin, we can use \(B = (\mu_0 / 4\pi) \Delta s (\sin \theta) / r^2\) as the Biot–Savart law. This is because \(r\) and \(\theta\) are essentially constant over the segment. Calculate \(\vec{B}\) (in unit-vector notation) at the \((x, y, z)\) coordinates \((a)\) \((0, 0, 5.0 \text{ m})\), \((b)\) \((0, 6.0 \text{ m}, 0)\), \((c)\) \((7.0 \text{ m}, 7.0 \text{ m}, 0)\), and \((d)\) \((-3.0 \text{ m}, -4.0 \text{ m}, 0)\).

**76** Figure 29-82 shows, in cross section, two long parallel wires spaced by distance \(d = 10.0 \text{ cm}\); each carries 100 A, out of the page in wire 1. Point \(P\) is on a perpendicular bisector of the line connecting the wires. In unit-vector notation, what is the net magnetic field at \(P\) if the current in wire 2 is (a) out of the page and (b) into the page?
In Fig. 29-83, two infinitely long wires carry equal currents $i$. Each follows a 90° arc on the circumference of the same circle of radius $R$. Show that the magnetic field $\vec{B}$ at the center of the circle is the same as the field $\vec{B}$ at a distance $R$ below an infinite straight wire carrying a current $i$ to the left.

A long wire carrying 100 A is perpendicular to the magnetic field lines of a uniform magnetic field of magnitude 5.0 mT. At what distance from the wire is the net magnetic field equal to zero?

A long, hollow, cylindrical conductor (with inner radius 2.0 mm and outer radius 4.0 mm) carries a current of 24 A distributed uniformly across its cross section. A long thin wire that is coaxial with the cylinder carries a current of 24 A in the opposite direction. What is the magnitude of the magnetic field (a) 1.0 mm, (b) 3.0 mm, and (c) 5.0 mm from the central axis of the wire and cylinder?

A long wire is known to have a radius greater than 4.0 mm and to carry a current that is uniformly distributed over its cross section. The magnitude of the magnetic field due to that current is 0.28 mT at a point 4.0 mm from the axis of the wire, and 0.20 mT at a point 10 mm from the axis of the wire. What is the radius of the wire?

Figure 29-84 shows a cross section of an infinite conducting sheet carrying a current per unit $x$-length of $\lambda$; the current emerges perpendicularly out of the page. (a) Use the Biot–Savart law and symmetry to show that for all points $P$ above the sheet and all points $P'$ below it, the magnetic field $\vec{B}$ is parallel to the sheet and directed as shown. (b) Use Ampere’s law to prove that $\vec{B} = \frac{1}{2} \mu_0 \lambda$ at all points $P$ and $P'$.

Figure 29-85 shows, in cross section, two parallel wires that are separated by distance $d = 18.6$ cm. Each carries 4.23 A, out of the page in wire 1 and into the page in wire 2. In unit-vector notation, what is the net magnetic field at point $P$ at distance $R = 34.2$ cm, due to the two currents?

In unit-vector notation, what is the magnetic field at point $P$ in Fig. 29-86 if $i = 10$ A and $a = 8.0$ cm? (Note that the wires are not long.)

Three long wires all lie in an $xy$ plane parallel to the $x$ axis. They are spaced equally, 10 cm apart. The two outer wires each carry a current of 5.0 A in the positive $x$ direction. What is the magnitude of the force on a 3.0 m section of either of the outer wires if the current in the center wire is 3.2 A (a) in the positive $x$ direction and (b) in the negative $x$ direction?

Figure 29-87 shows a cross section of a hollow cylindrical conductor of radii $a$ and $b$, carrying a uniformly distributed current $i$. (a) Show that the magnetic field magnitude $B(r)$ for the radial distance $r$ in the range $b < r < a$ is given by

$$B = \frac{\mu_0 i}{2\pi(a^2 - b^2)} \frac{r^2 - b^2}{r}.$$  

(b) Show that when $r = a$, this equation gives the magnetic field magnitude $B$ at the surface of a long straight wire carrying current $i$; when $r = b$, it gives zero magnetic field; and when $b = 0$, it gives the magnetic field inside a solid conductor of radius $a$ carrying current $i$. (c) Assume that $a = 2$ cm, $b = 1.8$ cm, and $i = 100$ A, and then plot $B(r)$ for the range $0 < r < 6$ cm.

Show that the magnitude of the magnetic field produced at the center of a rectangular loop of wire of length $L$ and width $W$, carrying a current $i$, is

$$B = \frac{2\mu_0 i}{\pi} \frac{(L^2 + W^2)^{1/2}}{LW}.$$  

Figure 29-88 shows a cross section of a long conducting coaxial cable and gives its radii ($a$, $b$, $c$). Equal but opposite currents $i$ are uniformly distributed in the two conductors. Derive expressions for $B(r)$ with radial distance $r$ in the ranges (a) $r < c$, (b) $c < r < b$, (c) $b < r < a$, and (d) $r > a$. (e) Test these expressions for all the special cases that occur to you. (f) Assume that $a = 2.0$ cm, $b = 1.8$ cm, $c = 0.40$ cm, and $i = 120$ A and plot the function $B(r)$ over the range $0 < r < 3$ cm.

Figure 29-89 is an idealized schematic drawing of a rail gun. Projectile $P$ sits between two wide rails of circular cross section; a source of current sends current through the rails and through the (conducting) projectile (a fuse is not used). (a) Let $w$ be the distance between the rails, $R$ the radius of each rail, and $i$ the current. Show that the force on the projectile is directed right along the rails and is given approximately by

$$F = \frac{i^2 \mu_0}{2\pi} \ln \frac{w + R}{R}$$  

(b) If the projectile starts from the left end of the rails at rest, find the speed $v$ at which it is expelled at the right. Assume that $i = 450$ kA, $w = 12$ mm, $R = 6.7$ cm, $L = 4.0$ m, and the projectile mass is 10 g.
CHAPTER 30

Induction and Inductance

30-1 FARADAY’S LAW AND LENZ’S LAW

Learning Objectives

After reading this module, you should be able to . . .

30.01 Identify that the amount of magnetic field piercing a surface (not skimming along the surface) is the magnetic flux \( \Phi \) through the surface.

30.02 Identify that an area vector for a flat surface is a vector that is perpendicular to the surface and that has a magnitude equal to the area of the surface.

30.03 Identify that any surface can be divided into area elements (patch elements) that are each small enough and flat enough for an area vector \( d\vec{A} \) to be assigned to it, with the vector perpendicular to the element and having a magnitude equal to the area of the element.

30.04 Calculate the magnetic flux \( \Phi \) through a surface by integrating the dot product of the magnetic field vector \( \vec{B} \) and the area vector \( d\vec{A} \) (for patch elements) over the surface, in magnitude-angle notation and unit-vector notation.

30.05 Identify that a current is induced in a conducting loop while the number of magnetic field lines intercepted by the loop is changing.

30.06 Identify that an induced current in a conducting loop is driven by an induced emf.

30.07 Apply Faraday’s law, which is the relationship between an induced emf in a conducting loop and the rate at which magnetic flux through the loop changes.

30.08 Extend Faraday’s law from a loop to a coil with multiple loops.

30.09 Identify the three general ways in which the magnetic flux through a coil can change.

30.10 Use a right-hand rule for Lenz’s law to determine the direction of induced emf and induced current in a conducting loop.

30.11 Identify that when a magnetic flux through a loop changes, the induced current in the loop sets up a magnetic field to oppose that change.

30.12 If an emf is induced in a conducting loop containing a battery, determine the net emf and calculate the corresponding current in the loop.

Key Ideas

- The magnetic flux \( \Phi_B \) through an area \( A \) in a magnetic field \( \vec{B} \) is defined as
  \[
  \Phi_B = \int \vec{B} \cdot d\vec{A},
  \]
  where the integral is taken over the area. The SI unit of magnetic flux is the weber, where 1 Wb = 1 T \cdot m^2.
- If \( \vec{B} \) is perpendicular to the area and uniform over it, the flux is
  \[
  \Phi_B = BA \quad (\vec{B} \perp A, \vec{B} \text{ uniform}).
  \]
- If the magnetic flux \( \Phi_B \) through an area bounded by a closed conducting loop changes with time, a current and an emf are produced in the loop; this process is called induction. The induced emf is
  \[
  \varepsilon = -\frac{d\Phi_B}{dt} \quad \text{(Faraday’s law)}.
  \]
- If the loop is replaced by a closely packed coil of \( N \) turns, the induced emf is
  \[
  \varepsilon = -N \frac{d\Phi_B}{dt}.
  \]
- An induced current has a direction such that the magnetic field due to the current opposes the change in the magnetic flux that induces the current. The induced emf has the same direction as the induced current.

What Is Physics?

In Chapter 29 we discussed the fact that a current produces a magnetic field. That fact came as a surprise to the scientists who discovered the effect. Perhaps even more surprising was the discovery of the reverse effect: A magnetic field can produce an electric field that can drive a current. This link between a magnetic field and the electric field it produces (induces) is now called *Faraday’s law of induction*. 
The observations by Michael Faraday and other scientists that led to this law were at first just basic science. Today, however, applications of that basic science are almost everywhere. For example, induction is the basis of the electric guitars that revolutionized early rock and still drive heavy metal and punk today. It is also the basis of the electric generators that power cities and transportation lines and of the huge induction furnaces that are commonplace in foundries where large amounts of metal must be melted rapidly.

Before we get to applications like the electric guitar, we must examine two simple experiments about Faraday’s law of induction.

Two Experiments

Let us examine two simple experiments to prepare for our discussion of Faraday’s law of induction.

First Experiment. Figure 30-1 shows a conducting loop connected to a sensitive ammeter. Because there is no battery or other source of emf included, there is no current in the circuit. However, if we move a bar magnet toward the loop, a current suddenly appears in the circuit. The current disappears when the magnet stops. If we then move the magnet away, a current again suddenly appears, but now in the opposite direction. If we experimented for a while, we would discover the following:

1. A current appears only if there is relative motion between the loop and the magnet (one must move relative to the other); the current disappears when the relative motion between them ceases.
2. Faster motion produces a greater current.
3. If moving the magnet’s north pole toward the loop causes, say, clockwise current, then moving the north pole away causes counterclockwise current. Moving the south pole toward or away from the loop also causes currents, but in the reversed directions.

The current produced in the loop is called an induced current; the work done per unit charge to produce that current (to move the conduction electrons that constitute the current) is called an induced emf; and the process of producing the current and emf is called induction.

Second Experiment. For this experiment we use the apparatus of Fig. 30-2, with the two conducting loops close to each other but not touching. If we close switch S, to turn on a current in the right-hand loop, the meter suddenly and briefly registers a current—an induced current—in the left-hand loop. If we then open the switch, another sudden and brief induced current appears in the left-hand loop, but in the opposite direction. We get an induced current (and thus an induced emf) only when the current in the right-hand loop is changing (either turning on or turning off) and not when it is constant (even if it is large).

The induced emf and induced current in these experiments are apparently caused when something changes—but what is that “something”? Faraday knew.

Faraday’s Law of Induction

Faraday realized that an emf and a current can be induced in a loop, as in our two experiments, by changing the amount of magnetic field passing through the loop. He further realized that the “amount of magnetic field” can be visualized in terms of the magnetic field lines passing through the loop. Faraday’s law of induction, stated in terms of our experiments, is this:

An emf is induced in the loop at the left in Figs. 30-1 and 30-2 when the number of magnetic field lines that pass through the loop is changing.

The magnet’s motion creates a current in the loop.

Figure 30-1 An ammeter registers a current in the wire loop when the magnet is moving with respect to the loop.

Closing the switch causes a current in the left-hand loop.

Figure 30-2 An ammeter registers a current in the left-hand wire loop just as switch S is closed (to turn on the current in the right-hand wire loop) or opened (to turn off the current in the right-hand loop). No motion of the coils is involved.
The actual number of field lines passing through the loop does not matter; the values of the induced emf and induced current are determined by the rate at which that number changes.

In our first experiment (Fig. 30-1), the magnetic field lines spread out from the north pole of the magnet. Thus, as we move the north pole closer to the loop, the number of field lines passing through the loop increases. That increase apparently causes conduction electrons in the loop to move (the induced current) and provides energy (the induced emf) for their motion. When the magnet stops moving, the number of field lines through the loop no longer changes and the induced current and induced emf disappear.

In our second experiment (Fig. 30-2), when the switch is open (no current), there are no field lines. However, when we turn on the current in the right-hand loop, the increasing current builds up a magnetic field around that loop and at the left-hand loop. While the field builds, the number of magnetic field lines through the left-hand loop increases. As in the first experiment, the increase in field lines through that loop apparently induces a current and an emf there. When the current in the right-hand loop reaches a final, steady value, the number of field lines through the left-hand loop no longer changes, and the induced current and induced emf disappear.

A Quantitative Treatment
To put Faraday’s law to work, we need a way to calculate the amount of magnetic field that passes through a loop. In Chapter 23, in a similar situation, we needed to calculate the amount of electric field that passes through a surface. There we defined an electric flux \( \Phi_E = \int \vec{E} \cdot d\vec{A} \). Here we define a magnetic flux: Suppose a loop enclosing an area \( A \) is placed in a magnetic field \( \vec{B} \). Then the magnetic flux through the loop is

\[
\Phi_B = \int \vec{B} \cdot d\vec{A} \quad \text{(magnetic flux through area \( A \)).} \tag{30-1}
\]

As in Chapter 23, \( d\vec{A} \) is a vector of magnitude \( dA \) that is perpendicular to a differential area \( dA \). As with electric flux, we want the component of the field that pierces the surface (not skims along it). The dot product of the field and the area vector automatically gives us that piercing component.

**Special Case.** As a special case of Eq. 30-1, suppose that the loop lies in a plane and that the magnetic field is perpendicular to the plane of the loop. Then we can write the dot product in Eq. 30-1 as \( B \, dA \cos 0^\circ = B \, dA \). If the magnetic field is also uniform, then \( B \) can be brought out in front of the integral sign. The remaining \( \int dA \) then gives just the area \( A \) of the loop. Thus, Eq. 30-1 reduces to

\[
\Phi_B = BA \quad \text{(\( B \perp \) area \( A \), \( B \) uniform).} \tag{30-2}
\]

**Unit.** From Eqs. 30-1 and 30-2, we see that the SI unit for magnetic flux is the tesla–square meter, which is called the weber (abbreviated Wb):

\[
1 \text{ weber} = 1 \text{ Wb} = 1 \text{ T} \cdot \text{m}^2. \tag{30-3}
\]

**Faraday’s Law.** With the notion of magnetic flux, we can state Faraday’s law in a more quantitative and useful way:

> The magnitude of the emf \( \mathcal{E} \) induced in a conducting loop is equal to the rate at which the magnetic flux \( \Phi_B \) through that loop changes with time.

As you will see below, the induced emf \( \mathcal{E} \) tends to oppose the flux change, so
Faraday’s law is formally written as

$$\mathcal{E} = -\frac{d\Phi_B}{dt}$$  \hspace{1cm} \text{(Faraday’s law),} \hspace{1cm} (30-4)$$

with the minus sign indicating that opposition. We often neglect the minus sign in Eq. 30-4, seeking only the magnitude of the induced emf.

If we change the magnetic flux through a coil of \(N\) turns, an induced emf appears in every turn and the total emf induced in the coil is the sum of these individual induced emfs. If the coil is tightly wound (closely packed), so that the same magnetic flux \(\Phi_B\) passes through all the turns, the total emf induced in the coil is

$$\mathcal{E} = -N \frac{d\Phi_B}{dt}$$  \hspace{1cm} \text{(coil of \(N\) turns).} \hspace{1cm} (30-5)$$

Here are the general means by which we can change the magnetic flux through a coil:

1. Change the magnitude \(B\) of the magnetic field within the coil.
2. Change either the total area of the coil or the portion of that area that lies within the magnetic field (for example, by expanding the coil or sliding it into or out of the field).
3. Change the angle between the direction of the magnetic field \(\vec{B}\) and the plane of the coil (for example, by rotating the coil so that field \(\vec{B}\) is first perpendicular to the plane of the coil and then is along that plane).

**Checkpoint 1**

The graph gives the magnitude \(B(t)\) of a uniform magnetic field that exists throughout a conducting loop, with the direction of the field perpendicular to the plane of the loop. Rank the five regions of the graph according to the magnitude of the emf induced in the loop, greatest first.

**Sample Problem 30.01  Induced emf in coil due to a solenoid**

The long solenoid \(S\) shown (in cross section) in Fig. 30-3 has 220 turns/cm and carries a current \(i = 1.5\) A; its diameter \(D\) is 3.2 cm. At its center we place a 130-turn closely packed coil \(C\) of diameter \(d = 2.1\) cm. The current in the solenoid is reduced to zero at a steady rate in 25 ms. What is the magnitude of the emf that is induced in coil \(C\) while the current in the solenoid is changing?

**Figure 30-3** A coil \(C\) is located inside a solenoid \(S\), which carries current \(i\).

**KEY IDEAS**

1. Because it is located in the interior of the solenoid, coil \(C\) lies within the magnetic field produced by current \(i\) in the solenoid; thus, there is a magnetic flux \(\Phi_B\) through coil \(C\).
2. Because current \(i\) decreases, flux \(\Phi_B\) also decreases.
3. As \(\Phi_B\) decreases, emf \(\mathcal{E}\) is induced in coil \(C\).
4. The flux through each turn of coil \(C\) depends on the area \(A\) and orientation of that turn in the solenoid’s magnetic field \(\vec{B}\). Because \(\vec{B}\) is uniform and directed perpendicular to area \(A\), the flux is given by Eq. 30-2 (\(\Phi_B = BA\)).
5. The magnitude \(B\) of the magnetic field in the interior of a solenoid depends on the solenoid’s current \(i\) and its number \(n\) of turns per unit length, according to Eq. 29-23 (\(B = \mu_0in\)).
### Calculations:
Because coil C consists of more than one turn, we apply Faraday’s law in the form of Eq. 30-5 
\( \varepsilon = -N \frac{d\Phi_B}{dt} \), where the number of turns \( N \) is 130 and \( \frac{d\Phi_B}{dt} \) is the rate at which the flux changes.

Because the current in the solenoid decreases at a steady rate, flux \( \Phi_B \) also decreases at a steady rate, and so we can write \( \frac{d\Phi_B}{dt} \) as \( \frac{\Delta \Phi_B}{\Delta t} \). Then, to evaluate \( \Delta \Phi_B \), we need the final and initial flux values. The final flux \( \Phi_{B,f} \) is zero because the final current in the solenoid is zero. To find the initial flux \( \Phi_{B,i} \), we note that area \( A \) is \( \frac{1}{2} \pi d^2 \) \( (= 3.464 \times 10^{-4} \text{ m}^2) \) and the number \( n \) is 220 turns/cm, or 22 000 turns/m. Substituting Eq. 29-23 into Eq. 30-2 then leads to

\[
\Phi_{B,i} = BA = (\mu_0 nA) \\
= (4 \pi \times 10^{-7} \text{T} \cdot \text{m/A})(1.5 \text{ A})(22 000 \text{ turns/m}) \\
\times (3.464 \times 10^{-4} \text{ m}^2) \\
= 1.44 \times 10^{-5} \text{ Wb}.
\]

Now we can write
\[
\frac{d\Phi_B}{dt} = \frac{\Delta \Phi_B}{\Delta t} = \frac{\Phi_{B,f} - \Phi_{B,i}}{\Delta t} \\
= \frac{(0 - 1.44 \times 10^{-5} \text{ Wb})}{25 \times 10^{-3} \text{s}} \\
= -5.76 \times 10^{-4} \text{ Wb/s} \\
= -5.76 \times 10^{-4} \text{ V}.
\]

We are interested only in magnitudes; so we ignore the minus signs here and in Eq. 30-5, writing
\[
\varepsilon = N \frac{d\Phi_B}{dt} = (130 \text{ turns})(5.76 \times 10^{-4} \text{ V}) \\
= 7.5 \times 10^{-2} \text{ V} \\
= 75 \text{ mV}.
\]  
(Answer)

### Lenz’s Law

Soon after Faraday proposed his law of induction, Heinrich Friedrich Lenz devised a rule for determining the direction of an induced current in a loop:

- An induced current has a direction such that the magnetic field due to the current opposes the change in the magnetic flux that induces the current.

Furthermore, the direction of an induced emf is that of the induced current. The key word in Lenz’s law is “opposition.” Let’s apply the law to the motion of the north pole toward the conducting loop in Fig. 30-4.

1. **Opposition to Pole Movement.** The approach of the magnet’s north pole in Fig. 30-4 increases the magnetic flux through the loop and thereby induces a current in the loop. From Fig. 29-22, we know that the loop then acts as a magnetic dipole with a south pole and a north pole, and that its magnetic dipole moment \( \vec{\mu} \) is directed from south to north. To oppose the magnetic flux increase being caused by the approaching magnet, the loop’s north pole (and thus \( \vec{\mu} \)) must face toward the approaching north pole so as to repel it (Fig. 30-4). Then the curled–straight right-hand rule for \( \vec{\mu} \) (Fig. 29-22) tells us that the current induced in the loop must be counterclockwise in Fig. 30-4.

If we next pull the magnet away from the loop, a current will again be induced in the loop. Now, however, the loop will have a south pole facing the retreating north pole of the magnet, so as to oppose the retreat. Thus, the induced current will be clockwise.

2. **Opposition to Flux Change.** In Fig. 30-4, with the magnet initially distant, no magnetic flux passes through the loop. As the north pole of the magnet then nears the loop with its magnetic field \( \vec{B} \) directed downward, the flux through the loop increases. To oppose this increase in flux, the induced current \( i \) must set up its own field \( \vec{B}_{\text{ind}} \) directed upward inside the loop, as shown in Fig. 30-5a; then the upward flux of field \( \vec{B}_{\text{ind}} \) opposes the increasing downward flux of field \( \vec{B} \). The curled–straight right-hand rule of Fig. 29-22 then tells us that \( i \) must be counterclockwise in Fig. 30-5a.
Heads Up. The flux of \( \vec{B}_{\text{ind}} \) always opposes the change in the flux of \( \vec{B} \), but \( \vec{B}_{\text{ind}} \) is not always opposite \( \vec{B} \). For example, if we next pull the magnet away from the loop in Fig. 30-4, the magnet’s flux \( \Phi_B \) is still downward through the loop, but it is now decreasing. The flux of \( \vec{B}_{\text{ind}} \) must now be downward inside the loop, to oppose that decrease (Fig. 30-5b). Thus, \( \vec{B}_{\text{ind}} \) and \( \vec{B} \) are now in the same direction. In Figs. 30-5c and d, the south pole of the magnet approaches and retreats from the loop, again with opposition to change.

Figure 30-5  The direction of the current \( i \) induced in a loop is such that the current’s magnetic field \( \vec{B}_{\text{ind}} \) opposes the change in the magnetic field \( \vec{B} \) inducing \( i \). The field \( \vec{B}_{\text{ind}} \) is always directed opposite an increasing field \( \vec{B} \) (a, c) and in the same direction as a decreasing field \( \vec{B} \) (b, d). The curled–straight right-hand rule gives the direction of the induced current based on the direction of the induced field.
Sample Problem 30.02  Induced emf and current due to a changing uniform $B$ field

Figure 30-6 shows a conducting loop consisting of a half-circle of radius $r = 0.20$ m and three straight sections. The half-circle lies in a uniform magnetic field $\vec{B}$ that is directed out of the page; the field magnitude is given by $B = 4.0t^2 + 2.0t + 3.0$, with $B$ in teslas and $t$ in seconds. An ideal battery with emf $\varepsilon_{bat} = 2.0$ V is connected to the loop. The resistance of the loop is $2.0$ $\Omega$.

(a) What are the magnitude and direction of the emf $\varepsilon_{ind}$ induced around the loop by field $\vec{B}$ at $t = 10$ s?

**KEY IDEAS**

1. According to Faraday’s law, the magnitude of $\varepsilon_{ind}$ is equal to the rate $d\Phi_B/dt$ at which the magnetic flux through the loop changes.

2. The flux through the loop depends on how much of the loop’s area lies within the flux and how the area is oriented in the magnetic field $\vec{B}$.

3. Because $\vec{B}$ is uniform and is perpendicular to the plane of the loop, the flux is given by Eq. 30-2 ($\Phi_B = BA$). (We don’t need to integrate $B$ over the area to get the flux.)

4. The induced field $B_{ind}$ (due to the induced current) must always oppose the change in the magnetic flux.

**Magnitude:** Using Eq. 30-2 and realizing that only the field magnitude $B$ changes in time (not the area $A$), we rewrite Faraday’s law, Eq. 30-4, as

$$\varepsilon_{ind} = \frac{d\Phi_B}{dt} = \frac{d(BA)}{dt} = A \frac{dB}{dt}.$$  

Because the flux penetrates the loop only within the half-circle, the area $A$ in this equation is $\frac{1}{2} \pi r^2$. Substituting this and the given expression for $B$ yields

$$\varepsilon_{ind} = A \frac{dB}{dt} = \frac{\pi r^2}{2} \frac{d}{dt} (4.0t^2 + 2.0t + 3.0)$$

$$= \frac{\pi r^2}{2} (8.0t^2 + 2.0).$$

At $t = 10$ s, then,

$$\varepsilon_{ind} = \frac{\pi (0.20 \text{ m})^2}{2} [8.0(10)^2 + 2.0]$$

$$= 5.152 \text{ V} \approx 5.2 \text{ V}.$$  

(Answer)

**Direction:** To find the direction of $\varepsilon_{ind}$, we first note that in Fig. 30-6 the flux through the loop is out of the page and increasing. Because the induced field $B_{ind}$ (due to the induced current) must oppose that increase, it must be into the page. Using the curled–straight right-hand rule (Fig. 30-5c), we find that the induced current is clockwise around the loop, and thus so is the induced emf $\varepsilon_{ind}$.

(b) What is the current in the loop at $t = 10$ s?

**KEY IDEA**

The point here is that two emfs tend to move charges around the loop.

**Calculation:** The induced emf $\varepsilon_{ind}$ tends to drive a current clockwise around the loop; the battery’s emf $\varepsilon_{bat}$ tends to drive a current counterclockwise. Because $\varepsilon_{ind}$ is greater than $\varepsilon_{bat}$, the net emf $\varepsilon_{net}$ is clockwise, and thus so is the current. To find the current at $t = 10$ s, we use Eq. 27-2 ($i = \varepsilon_{net}/R$):

$$i = \frac{\varepsilon_{net}}{R} = \frac{\varepsilon_{ind} - \varepsilon_{bat}}{R}$$

$$= \frac{5.152 \text{ V} - 2.0 \text{ V}}{2.0 \Omega} = 1.58 \text{ A} \approx 1.6 \text{ A}.$$  

(Answer)

Sample Problem 30.03  Induced emf due to a changing nonuniform $B$ field

Figure 30-7 shows a rectangular loop of wire immersed in a nonuniform and varying magnetic field $\vec{B}$ that is perpendicular to and directed into the page. The field’s magnitude is given by $B = 4r^2x^2$, with $B$ in teslas, $t$ in seconds, and $x$ in meters. (Note that the function depends on both time and position.) The loop has width $W = 3.0$ m and height $H = 2.0$ m. What are the magnitude and direction of the induced emf $\varepsilon$ around the loop at $t = 0.10$ s?

**KEY IDEAS**

1. Because the magnitude of the magnetic field $\vec{B}$ is changing with time, the magnetic flux $\Phi_B$ through the loop is also changing.

2. The changing flux induces an emf $\varepsilon$ in the loop according to Faraday’s law, which we can write as $\varepsilon = d\Phi_B/dt$.

3. To use that law, we need an expression for the flux $\Phi_B$ at
If the field varies with position, we must integrate to get the flux through the loop.

Figure 30-7 A closed conducting loop, of width \( W \) and height \( H \), lies in a nonuniform, varying magnetic field that points directly into the page. To apply Faraday’s law, we use the vertical strip of height \( H \), width \( dx \), and area \( dA \).

any time \( t \). However, because \( B \) is not uniform over the area enclosed by the loop, we cannot use Eq. 30-2 (\( \Phi_B = BA \)) to find that expression; instead we must use Eq. 30-1 (\( \Phi_B = \int \overrightarrow{B} \cdot d\overrightarrow{A} \)).

Calculations: In Fig. 30-7, \( \overrightarrow{B} \) is perpendicular to the plane of the loop (and hence parallel to the differential area vector \( d\overrightarrow{A} \)); so the dot product in Eq. 30-1 gives \( B \, dA \). Because the magnetic field varies with the coordinate \( x \) but not with the coordinate \( y \), we can take the differential area \( dA \) to be the area of a vertical strip of height \( H \) and width \( dx \) (as shown in Fig. 30-7). Then \( dA = H \, dx \), and the flux through the loop is

\[
\Phi_B = \int B \, dA = \int BH \, dx = \int 4t^2x^2H \, dx.
\]

Treating \( t \) as a constant for this integration and inserting the integration limits \( x = 0 \) and \( x = 3.0 \, \text{m} \), we obtain

\[
\Phi_B = 4t^2H \int_0^{3.0} x^2 \, dx = 4t^2H \left[ \frac{x^3}{3} \right]_0^{3.0} = 72t^2,
\]

where we have substituted \( H = 2.0 \, \text{m} \) and \( \Phi_B \) is in webers. Now we can use Faraday’s law to find the magnitude of \( \varepsilon \) at any time \( t \):

\[
\varepsilon = \frac{d\Phi_B}{dt} = \frac{d(72t^2)}{dt} = 144t,
\]

in which \( \varepsilon \) is in volts. At \( t = 0.10 \, \text{s} \),

\[
\varepsilon = (144 \, \text{V/s})(0.10 \, \text{s}) = 14 \, \text{V}.
\]

(Answer)

The flux of \( \overrightarrow{B} \) through the loop is into the page in Fig. 30-7 and is increasing in magnitude because \( B \) is increasing in magnitude with time. By Lenz’s law, the field \( B_{\text{ind}} \) of the induced current opposes this increase and so is directed out of the page. The curled–straight right-hand rule in Fig. 30-5 then tells us that the induced current is counterclockwise around the loop, and thus so is the induced emf \( \varepsilon \).
induction.) The faster you move the magnet, the more rapidly your applied force does work and the greater the rate at which your energy is transferred to thermal energy in the loop; that is, the power of the transfer is greater.

Regardless of how current is induced in a loop, energy is always transferred to thermal energy during the process because of the electrical resistance of the loop (unless the loop is superconducting). For example, in Fig. 30-2, when switch S is closed and a current is briefly induced in the left-hand loop, energy is transferred from the battery to thermal energy in that loop.

Figure 30-8 shows another situation involving induced current. A rectangular loop of wire of width $L$ has one end in a uniform external magnetic field that is directed perpendicularly into the plane of the loop. This field may be produced, for example, by a large electromagnet. The dashed lines in Fig. 30-8 show the assumed limits of the magnetic field; the fringing of the field at its edges is neglected. You are to pull this loop to the right at a constant velocity $v$.

Flux Change. The situation of Fig. 30-8 does not differ in any essential way from that of Fig. 30-1. In each case a magnetic field and a conducting loop are in relative motion; in each case the flux of the field through the loop is changing with time. It is true that in Fig. 30-1 the flux is changing because $B$ is changing and in Fig. 30-8 the flux is changing because the area of the loop still in the magnetic field is changing, but that difference is not important. The important difference between the two arrangements is that the arrangement of Fig. 30-8 makes calculations easier. Let us now calculate the rate at which you do mechanical work as you pull steadily on the loop in Fig. 30-8.

Rate of Work. As you will see, to pull the loop at a constant velocity $v$, you must apply a constant force $F$ to the loop because a magnetic force of equal magnitude but opposite direction acts on the loop to oppose you. From Eq. 7-48, the rate at which you do work—that is, the power—is then

$$P = Fv,$$  \hspace{1cm} (30-6)

where $F$ is the magnitude of your force. We wish to find an expression for $P$ in terms of the magnitude $B$ of the magnetic field and the characteristics of the loop—namely, its resistance $R$ to current and its dimension $L$.

As you move the loop to the right in Fig. 30-8, the portion of its area within the magnetic field decreases. Thus, the flux through the loop also decreases and, according to Faraday’s law, a current is produced in the loop. It is the presence of this current that causes the force that opposes your pull.

Induced emf. To find the current, we first apply Faraday’s law. When $x$ is the length of the loop still in the magnetic field, the area of the loop still in the field is $Lx$. Then from Eq. 30-2, the magnitude of the flux through the loop is

$$\Phi_B = BA = BLx.$$  \hspace{1cm} (30-7)
As \( x \) decreases, the flux decreases. Faraday’s law tells us that with this flux decrease, an emf is induced in the loop. Dropping the minus sign in Eq. 30-4 and using Eq. 30-7, we can write the magnitude of this emf as

\[
\mathcal{E} = \frac{d\Phi_B}{dt} = BL \frac{dx}{dt} = BLv, \tag{30-8}
\]

in which we have replaced \( \frac{dx}{dt} \) with \( v \), the speed at which the loop moves.

Figure 30-9 shows the loop as a circuit: induced emf \( \mathcal{E} \) is represented on the left, and the collective resistance \( R \) of the loop is represented on the right. The direction of the induced current \( i \) is obtained with a right-hand rule as in Fig. 30-5b for decreasing flux; applying the rule tells us that the current must be clockwise, and \( \mathcal{E} \) must have the same direction.

**Induced Current.** To find the magnitude of the induced current, we cannot apply the loop rule for potential differences in a circuit because, as you will see in Module 30-3, we cannot define a potential difference for an induced emf. However, we can apply the equation \( i = \mathcal{E}/R \). With Eq. 30-8, this becomes

\[
i = \frac{BLv}{R}. \tag{30-9}
\]

Because three segments of the loop in Fig. 30-8 carry this current through the magnetic field, sideways deflecting forces act on those segments. From Eq. 28-26 we know that such a deflecting force is, in general notation,

\[
\vec{F}_d = i\vec{L} \times \vec{B}. \tag{30-10}
\]

In Fig. 30-8, the deflecting forces acting on the three segments of the loop are marked \( \vec{F}_1 \), \( \vec{F}_2 \), and \( \vec{F}_3 \). Note, however, that from the symmetry, forces \( \vec{F}_2 \) and \( \vec{F}_3 \) are equal in magnitude and cancel. This leaves only force \( \vec{F}_1 \), which is directed opposite your force \( \vec{F} \) on the loop and thus is the force opposing you. So, \( \vec{F} = -\vec{F}_1 \).

Using Eq. 30-10 to obtain the magnitude of \( \vec{F}_1 \) and noting that the angle between \( \vec{B} \) and the length vector \( \vec{L} \) for the left segment is 90°, we write

\[
F = F_1 = iLB \sin 90° = iLB. \tag{30-11}
\]

Substituting Eq. 30-9 for \( i \) in Eq. 30-11 then gives us

\[
F = \frac{B^2L^2v}{R}. \tag{30-12}
\]

Because \( B \), \( L \), and \( R \) are constants, the speed \( v \) at which you move the loop is constant if the magnitude \( F \) of the force you apply to the loop is also constant.

**Rate of Work.** By substituting Eq. 30-12 into Eq. 30-6, we find the rate at which you do work on the loop as you pull it from the magnetic field:

\[
P = Fv = \frac{B^2L^2v^2}{R} \quad \text{(rate of doing work)}. \tag{30-13}
\]

**Thermal Energy.** To complete our analysis, let us find the rate at which thermal energy appears in the loop as you pull it along at constant speed. We calculate it from Eq. 26-27,

\[
P = i^2R. \tag{30-14}
\]

Substituting for \( i \) from Eq. 30-9, we find

\[
P = \left( \frac{BLv}{R} \right)^2 R = \frac{B^2L^2v^2}{R} \quad \text{(thermal energy rate),} \tag{30-15}
\]

which is exactly equal to the rate at which you are doing work on the loop (Eq. 30-13). Thus, the work that you do in pulling the loop through the magnetic field appears as thermal energy in the loop.
Suppose we replace the conducting loop of Fig. 30-8 with a solid conducting plate. If we then move the plate out of the magnetic field as we did the loop (Fig. 30-10), the relative motion of the field and the conductor again induces a current in the conductor. Thus, we again encounter an opposing force and must do work because of the induced current. With the plate, however, the conduction electrons making up the induced current do not follow one path as they do with the loop. Instead, the electrons swirl about within the plate as if they were caught in an eddy (whirlpool) of water. Such a current is called an *eddy current* and can be represented, as it is in Fig. 30-10a, as if it followed a single path.

As with the conducting loop of Fig. 30-8, the current induced in the plate results in mechanical energy being dissipated as thermal energy. The dissipation is more apparent in the arrangement of Fig. 30-10b; a conducting plate, free to rotate about a pivot, is allowed to swing down through a magnetic field like a pendulum. Each time the plate enters and leaves the field, a portion of its mechanical energy is transferred to its thermal energy. After several swings, no mechanical energy remains and the warmed-up plate just hangs from its pivot.

**Checkpoint 3**

The figure shows four wire loops, with edge lengths of either $L$ or $2L$. All four loops will move through a region of uniform magnetic field $\vec{B}$ (directed out of the page) at the same constant velocity. Rank the four loops according to the maximum magnitude of the emf induced as they move through the field, greatest first.

![Diagram of four wire loops](image)

---

**30-3 INDUCTED ELECTRIC FIELDS**

**Learning Objectives**

*After reading this module, you should be able to . . .*

- **30.16** Identify that a changing magnetic field induces an electric field, regardless of whether there is a conducting loop.
- **30.17** Apply Faraday’s law to relate the electric field $\vec{E}$ induced along a closed path (whether it has conducting material or not) to the rate of change $d\Phi_B/dt$ of the magnetic flux encircled by the path.
- **30.18** Identify that an electric potential cannot be associated with an induced electric field.

**Key Ideas**

- An emf is induced by a changing magnetic flux even if the loop through which the flux is changing is not a physical conductor but an imaginary line. The changing magnetic field induces an electric field $\vec{E}$ at every point of such a loop; the induced emf is related to $\vec{E}$ by
  
  \[
  \mathcal{E} = \oint \vec{E} \cdot d\vec{s}.
  \]

- Using the induced electric field, we can write Faraday’s law in its most general form as
  
  \[
  \oint \vec{E} \cdot d\vec{s} = -\frac{d\Phi_B}{dt} \quad \text{(Faraday’s law)}.
  \]

A changing magnetic field induces an electric field $\vec{E}$. 

---

---

---
**Induced Electric Fields**

Let us place a copper ring of radius $r$ in a uniform external magnetic field, as in Fig. 30-11a. The field—neglecting fringing—fills a cylindrical volume of radius $R$. Suppose that we increase the strength of this field at a steady rate, perhaps by increasing—in an appropriate way—the current in the windings of the electromagnet that produces the field. The magnetic flux through the ring will then change at a steady rate and—by Faraday’s law—an induced emf and thus an induced current will appear in the ring. From Lenz’s law we can deduce that the direction of the induced current is counterclockwise in Fig. 30-11a.

If there is a current in the copper ring, an electric field must be present along the ring because an electric field is needed to do the work of moving the conduction electrons. Moreover, the electric field must have been produced by the changing magnetic flux. This induced electric field $\mathbf{E}$ is just as real as an electric field produced by static charges; either field will exert a force $q_0\mathbf{E}$ on a particle of charge $q_0$.

By this line of reasoning, we are led to a useful and informative restatement of Faraday’s law of induction:

> A changing magnetic field produces an electric field.

The striking feature of this statement is that the electric field is induced even if there is no copper ring. Thus, the electric field would appear even if the changing magnetic field were in a vacuum.

To fix these ideas, consider Fig. 30-11b, which is just like Fig. 30-11a except the copper ring has been replaced by a hypothetical circular path of radius $r$. We assume, as previously, that the magnetic field $\mathbf{B}$ is increasing in magnitude at a constant rate $dB/dt$. The electric field induced at various points around the

---

**Figure 30-11** (a) If the magnetic field increases at a steady rate, a constant induced current appears, as shown, in the copper ring of radius $r$. (b) An induced electric field exists even when the ring is removed; the electric field is shown at four points. (c) The complete picture of the induced electric field, displayed as field lines. (d) Four similar closed paths that enclose identical areas. Equal emfs are induced around paths 1 and 2, which lie entirely within the region of changing magnetic field. A smaller emf is induced around path 3, which only partially lies in that region. No net emf is induced around path 4, which lies entirely outside the magnetic field.
circular path must—from the symmetry—be tangent to the circle, as Fig. 30-11 shows.* Hence, the circular path is an electric field line. There is nothing special about the circle of radius $r$, so the electric field lines produced by the changing magnetic field must be a set of concentric circles, as in Fig. 30-11c.

As long as the magnetic field is increasing with time, the electric field represented by the circular field lines in Fig. 30-11c will be present. If the magnetic field remains constant with time, there will be no induced electric field and thus no electric field lines. If the magnetic field is decreasing with time (at a constant rate), the electric field lines will still be concentric circles as in Fig. 30-11c, but they will now have the opposite direction. All this is what we have in mind when we say “A changing magnetic field produces an electric field.”

**A Reformulation of Faraday’s Law**

Consider a particle of charge $q_0$ moving around the circular path of Fig. 30-11b. The work $W$ done on it in one revolution by the induced electric field is $W = \mathcal{E}q_0$, where $\mathcal{E}$ is the induced emf—that is, the work done per unit charge in moving the test charge around the path. From another point of view, the work is

$$W = \int \vec{F} \cdot d\vec{s} = (q_0E)(2\pi r),$$

(30-16)

where $q_0E$ is the magnitude of the force acting on the test charge and $2\pi r$ is the distance over which that force acts. Setting these two expressions for $W$ equal to each other and canceling $q_0$, we find that

$$\mathcal{E} = 2\pi E.$$  

(30-17)

Next we rewrite Eq. 30-16 to give a more general expression for the work done on a particle of charge $q_0$ moving along any closed path:

$$W = \oint \vec{F} \cdot d\vec{s} = q_0 \oint \vec{E} \cdot d\vec{s}.$$  

(30-18)

(The loop on each integral sign indicates that the integral is to be taken around the closed path.) Substituting $\mathcal{E}q_0$ for $W$, we find that

$$\mathcal{E} = \oint \vec{E} \cdot d\vec{s}.$$  

(30-19)

This integral reduces at once to Eq. 30-17 if we evaluate it for the special case of Fig. 30-11b.

**Meaning of emf.** With Eq. 30-19, we can expand the meaning of induced emf. Up to this point, induced emf has meant the work per unit charge done in maintaining current due to a changing magnetic flux, or it has meant the work done per unit charge on a charged particle that moves around a closed path in a changing magnetic flux. However, with Fig. 30-11b and Eq. 30-19, an induced emf can exist without the need of a current or particle: An induced emf is the sum—via integration—of quantities $\vec{E} \cdot d\vec{s}$ around a closed path, where $\vec{E}$ is the electric field induced by a changing magnetic flux and $d\vec{s}$ is a differential length vector along the path.

If we combine Eq. 30-19 with Faraday’s law in Eq. 30-4 ($\mathcal{E} = -d\Phi_B/dt$), we can rewrite Faraday’s law as

$$\oint \vec{E} \cdot d\vec{s} = -\frac{d\Phi_B}{dt} \quad \text{(Faraday’s law)}.$$  

(30-20)

---

*Arguments of symmetry would also permit the lines of $\vec{E}$ around the circular path to be radial, rather than tangential. However, such radial lines would imply that there are free charges, distributed symmetrically about the axis of symmetry, on which the electric field lines could begin or end; there are no such charges.
This equation says simply that a changing magnetic field induces an electric field.
The changing magnetic field appears on the right side of this equation, the elec-
tric field on the left.

Faraday’s law in the form of Eq. 30-20 can be applied to any closed path that
 can be drawn in a changing magnetic field. Figure 30-11, for example, shows four
such paths, all having the same shape and area but located in different positions
in the changing field. The induced emfs $\mathcal{E}$ ($= \oint \vec{E} \cdot d\vec{s}$) for paths 1 and 2 are equal
because these paths lie entirely in the magnetic field and thus have the same
value of $d\Phi_B/dt$. This is true even though the electric field vectors at points along
these paths are different, as indicated by the patterns of electric field lines in the
figure. For path 3 the induced emf is smaller because the enclosed flux $\Phi_B$ (hence
$d\Phi_B/dt$) is smaller, and for path 4 the induced emf is zero even though the electric
field is not zero at any point on the path.

A New Look at Electric Potential

Induced electric fields are produced not by static charges but by a changing mag-
netic flux. Although electric fields produced in either way exert forces on charged
particles, there is an important difference between them. The simplest evidence
of this difference is that the field lines of induced electric fields form closed loops,
as in Fig. 30-11c. Field lines produced by static charges never do so but must start
on positive charges and end on negative charges. Thus, a field line from a charge
can never loop around and back onto itself as we see for each of the field lines
in Fig. 30-11c.

In a more formal sense, we can state the difference between electric fields
produced by induction and those produced by static charges in these words:

\begin{center}
Electric potential has meaning only for electric fields that are produced by static
charges; it has no meaning for electric fields that are produced by induction.
\end{center}

You can understand this statement qualitatively by considering what happens
to a charged particle that makes a single journey around the circular path in
Fig. 30-11b. It starts at a certain point and, on its return to that same point, has
experienced an emf $\mathcal{E}$ of, let us say, 5 V; that is, work of 5 J/C has been done on the
particle by the electric field, and thus the particle should then be at a point that is
5 V greater in potential. However, that is impossible because the particle is back
at the same point, which cannot have two different values of potential. Thus, po-
tential has no meaning for electric fields that are set up by changing magnetic
fields.

We can take a more formal look by recalling Eq. 24-18, which defines the
potential difference between two points $i$ and $f$ in an electric field $\vec{E}$ in terms of
an integration between those points:

$$V_f - V_i = -\int_i^f \vec{E} \cdot d\vec{s}. \tag{30-21}$$

In Chapter 24 we had not yet encountered Faraday’s law of induction; so the elec-
tric fields involved in the derivation of Eq. 24-18 were those due to static charges.
If $i$ and $f$ in Eq. 30-21 are the same point, the path connecting them is a closed
loop, $V_i$ and $V_f$ are identical, and Eq. 30-21 reduces to

$$\oint \vec{E} \cdot d\vec{s} = 0. \tag{30-22}$$

However, when a changing magnetic flux is present, this integral is not zero but is
$-d\Phi_B/dt$, as Eq. 30-20 asserts. Thus, assigning electric potential to an induced
electric field leads us to a contradiction. We must conclude that electric potential
has no meaning for electric fields associated with induction.
Checkpoint 4

The figure shows five lettered regions in which a uniform magnetic field extends either directly out of the page or into the page, with the direction indicated only for region \( a \). The field is increasing in magnitude at the same steady rate in all five regions; the regions are identical in area. Also shown are four numbered paths along which \( \mathbf{E} \cdot d\mathbf{s} \) has the magnitudes given below in terms of a quantity “mag.” Determine whether the magnetic field is directed into or out of the page for regions \( b \) through \( e \).

Sample Problem 30.04  Induced electric field due to changing \( B \) field, inside and outside

In Fig. 30-11b, take \( R = 8.5 \text{ cm} \) and \( dB/dt = 0.13 \text{ T/s} \).

(a) Find an expression for the magnitude \( E \) of the induced electric field at points within the magnetic field, at radius \( r \) from the center of the magnetic field. Evaluate the expression for \( r = 5.2 \text{ cm} \).

**KEY IDEA**

An electric field is induced by the changing magnetic field, according to Faraday’s law.

**Calculations:** To calculate the field magnitude \( E \), we apply Faraday’s law in the form of Eq. 30-20. We use a circular path of integration with radius \( r \leq R \) because we want \( E \) for points within the magnetic field. We assume from the symmetry that \( \mathbf{E} \) in Fig. 30-11b is tangent to the circular path at all points. The path vector \( d\mathbf{s} \) is also always tangent to the circular path; so the dot product \( \mathbf{E} \cdot d\mathbf{s} \) in Eq. 30-20 must have the magnitude \( E \, ds \) at all points on the path. We can also assume from the symmetry that \( E \) has the same value at all points along the circular path. Then the left side of Eq. 30-20 becomes

\[
\oint \mathbf{E} \cdot d\mathbf{s} = \oint E \, ds = E \oint ds = E(2\pi r). \tag{30-23}
\]

(The integral \( \oint ds \) is the circumference \( 2\pi r \) of the circular path.)

Next, we need to evaluate the right side of Eq. 30-20. Because \( B \) is uniform over the area \( A \) encircled by the path of integration and is directed perpendicular to that area, the magnetic flux is given by Eq. 30-2:

\[
\Phi_B = BA = B(\pi r^2). \tag{30-24}
\]

Substituting this and Eq. 30-23 into Eq. 30-20 and dropping the minus sign, we find that

\[
E(2\pi r) = (\pi r^2) \frac{dB}{dt},
\]

or

\[
E = \frac{r}{2} \frac{dB}{dt}. \tag{Answer} \quad (30-25)
\]

Equation 30-25 gives the magnitude of the electric field at any point for which \( r \leq R \) (that is, within the magnetic field). Substituting given values yields, for the magnitude of \( E \) at \( r = 5.2 \text{ cm} \),

\[
E = \frac{(5.2 \times 10^{-2} \text{ m})}{2} \times \frac{0.13 \text{ T/s}}{2} = 0.0034 \text{ V/m} = 3.4 \text{ mV/m}. \tag{Answer}
\]

(b) Find an expression for the magnitude \( E \) of the induced electric field at points that are outside the magnetic field, at radius \( r \) from the center of the magnetic field. Evaluate the expression for \( r = 12.5 \text{ cm} \).

**KEY IDEAS**

Here again an electric field is induced by the changing magnetic field, according to Faraday’s law, except that now we use a circular path of integration with radius \( r \geq R \) because we want to evaluate \( E \) for points outside the magnetic field. Proceeding as in (a), we again obtain Eq. 30-23. However, we do not then obtain Eq. 30-24 because the new path of integration is now outside the magnetic field, and so the magnetic flux encircled by the new path is only that in the area \( \pi R^2 \) of the magnetic field region.

**Calculations:** We can now write

\[
\Phi_B = BA = B(\pi R^2). \tag{30-26}
\]
Substituting this and Eq. 30-23 into Eq. 30-20 (without the minus sign) and solving for $E$ yield

$$E = \frac{R^2}{2r} \frac{dB}{dt}.$$  

(Answer) (30-27)

Because $E$ is not zero here, we know that an electric field is induced even at points that are outside the changing magnetic field, an important result that (as you will see in Module 31-6) makes transformers possible.

With the given data, Eq. 30-27 yields the magnitude of $E$ at $r = 12.5$ cm:

$$E = \frac{(8.5 \times 10^{-2} \text{ m})^2}{(2)(12.5 \times 10^{-2} \text{ m})} (0.13 \text{ T/s})$$

$$= 3.8 \times 10^{-3} \text{ V/m} = 3.8 \text{ mV/m}. \quad \text{(Answer)}$$

**30-4 INDUCTORS AND INDUCTANCE**

**Learning Objectives**

*After reading this module, you should be able to . . .*

30.19 Identify an inductor.

30.20 For an inductor, apply the relationship between inductance $L$, total flux $N\Phi$, and current $i$.

30.21 For a solenoid, apply the relationship between the inductance per unit length $L/l$, the area $A$ of each turn, and the number of turns per unit length $n$.

**Key Ideas**

- An inductor is a device that can be used to produce a known magnetic field in a specified region. If a current $i$ is established through each of the $N$ windings of an inductor, a magnetic flux $\Phi_B$ links those windings. The inductance $L$ of the inductor is

$$L = \frac{N\Phi_B}{i} \quad \text{(inductance defined).}$$

- The SI unit of inductance is the henry (H), where $1 \text{ H} = 1 \text{ T} \cdot \text{m}^2/\text{A}$.

- The inductance per unit length near the middle of a long solenoid of cross-sectional area $A$ and $n$ turns per unit length is

$$\frac{L}{l} = \mu_0 n^2 A \quad \text{(solenoid).}$$

**Inductors and Inductance**

We found in Chapter 25 that a capacitor can be used to produce a desired electric field. We considered the parallel-plate arrangement as a basic type of capacitor. Similarly, an **inductor** (symbol ) can be used to produce a desired magnetic field. We shall consider a long solenoid (more specifically, a short length near the middle of a long solenoid, to avoid any fringing effects) as our basic type of inductor.

If we establish a current $i$ in the windings (turns) of the solenoid we are taking as our inductor, the current produces a magnetic flux $\Phi_B$ through the central region of the inductor. The **inductance** of the inductor is then defined in terms of that flux as

$$L = \frac{N\Phi_B}{i} \quad \text{(inductance defined),}$$

(30-28)
The crude inductors with which Michael Faraday discovered the law of induction. In those days amenities such as insulated wire were not commercially available. It is said that Faraday insulated his wires by wrapping them with strips cut from one of his wife’s petticoats.

The inductance \( L \) is thus a measure of the flux linkage produced by the inductor per unit of current.

Because the SI unit of magnetic flux is the tesla–square meter, the SI unit of inductance is the tesla–square meter per ampere (T⋅m\(^2\)/A). We call this the henry (H), after American physicist Joseph Henry, the codiscoverer of the law of induction and a contemporary of Faraday. Thus,

\[
1 \text{ henry} = 1 \text{ H} = 1 \text{T} \cdot \text{m}^2/\text{A}. \tag{30-29}
\]

Through the rest of this chapter we assume that all inductors, no matter what their geometric arrangement, have no magnetic materials such as iron in their vicinity. Such materials would distort the magnetic field of an inductor.

**Inductance of a Solenoid**

Consider a long solenoid of cross-sectional area \( A \). What is the inductance per unit length near its middle? To use the defining equation for inductance (Eq. 30-28), we must calculate the flux linkage set up by a given current in the solenoid windings. Consider a length \( l \) near the middle of this solenoid. The flux linkage there is

\[
N \Phi_B = (nl)(BA),
\]

in which \( n \) is the number of turns per unit length of the solenoid and \( B \) is the magnitude of the magnetic field within the solenoid.

The magnitude \( B \) is given by Eq. 29-23,

\[
B = \mu_0 i n,
\]

and so from Eq. 30-28,

\[
L = \frac{N \Phi_B}{i} = \frac{(nl)(BA)}{i} = \frac{(nl)(\mu_0 in)(A)}{i} = \mu_0 n^2 l A.
\] \hspace{1cm} (30-30)

Thus, the inductance per unit length near the center of a long solenoid is

\[
\frac{L}{l} = \mu_0 n^2 A \quad \text{(solenoid).} \tag{30-31}
\]

Inductance—like capacitance—depends only on the geometry of the device. The dependence on the square of the number of turns per unit length is to be expected. If you, say, triple \( n \), you not only triple the number of turns \( (N) \) but you also triple the flux \( (\Phi_B = BA = \mu_0 i n A) \) through each turn, multiplying the flux linkage \( N \Phi_B \) and thus the inductance \( L \) by a factor of 9.

If the solenoid is very much longer than its radius, then Eq. 30-30 gives its inductance to a good approximation. This approximation neglects the spreading of the magnetic field lines near the ends of the solenoid, just as the parallel-plate capacitor formula \( (C = \epsilon_0 A/d) \) neglects the fringing of the electric field lines near the edges of the capacitor plates.

From Eq. 30-30, and recalling that \( n \) is a number per unit length, we can see that an inductance can be written as a product of the permeability constant \( \mu_0 \) and a quantity with the dimensions of a length. This means that \( \mu_0 \) can be expressed in the unit henry per meter:

\[
\mu_0 = 4\pi \times 10^{-7} \text{ T} \cdot \text{m}/\text{A}
= 4\pi \times 10^{-7} \text{ H}/\text{m}. \tag{30-32}
\]

The latter is the more common unit for the permeability constant.
### 30-5 SELF-INDUCTION

#### Learning Objectives

After reading this module, you should be able to . . .

- **30.22** Identify that an induced emf appears in a coil when the current through the coil is changing.
- **30.23** Apply the relationship between the induced emf in a coil, the coil's inductance \(L\), and the rate \(\frac{di}{dt}\) at which the current is changing.
- **30.24** When an emf is induced in a coil because the current in the coil is changing, determine the direction of the emf by using Lenz’s law to show that the emf always opposes the change in the current, attempting to maintain the initial current.

#### Key Ideas

- If a current \(i\) in a coil changes with time, an emf is induced in the coil. This self-induced emf is

\[
\mathcal{E}_L = -L \frac{di}{dt}.
\]

- The direction of \(\mathcal{E}_L\) is found from Lenz's law: The self-induced emf acts to oppose the change that produces it.

#### Self-Induction

If two coils—which we can now call inductors—are near each other, a current \(i\) in one coil produces a magnetic flux \(\Phi_B\) through the second coil. We have seen that if we change this flux by changing the current, an induced emf appears in the second coil according to Faraday’s law. An induced emf appears in the first coil as well.

An induced emf \(\mathcal{E}_L\) appears in any coil in which the current is changing.

This process (see Fig. 30-13) is called **self-induction**, and the emf that appears is called a **self-induced emf**. It obeys Faraday’s law of induction just as other induced emfs do.

For any inductor, Eq. 30-28 tells us that

\[
N\Phi_B = Li. \quad (30-33)
\]

Faraday’s law tells us that

\[
\mathcal{E}_L = -\frac{d(N\Phi_B)}{dt}. \quad (30-34)
\]

By combining Eqs. 30-33 and 30-34 we can write

\[
\mathcal{E}_L = -L \frac{di}{dt} \quad \text{(self-induced emf)}. \quad (30-35)
\]

Thus, in any inductor (such as a coil, a solenoid, or a toroid) a self-induced emf appears whenever the current changes with time. The magnitude of the current has no influence on the magnitude of the induced emf; only the rate of change of the current counts.

**Direction.** You can find the direction of a self-induced emf from Lenz’s law. The minus sign in Eq. 30-35 indicates that—as the law states—the self-induced emf \(\mathcal{E}_L\) has the orientation such that it opposes the change in current \(i\). We can drop the minus sign when we want only the magnitude of \(\mathcal{E}_L\).

Suppose that you set up a current \(i\) in a coil and arrange to have the current increase with time at a rate \(\frac{di}{dt}\). In the language of Lenz’s law, this increase in the current in the coil is the “change” that the self-induction must oppose. Thus, a self-induced emf must appear in the coil, pointing so as to oppose the increase in the current, trying (but failing) to maintain the initial condition, as

![Figure 30-13](image-url)
shown in Fig. 30-14a. If, instead, the current decreases with time, the self-induced emf must point in a direction that tends to oppose the decrease (Fig. 30-14b), again trying to maintain the initial condition.

**Electric Potential.** In Module 30-3 we saw that we cannot define an electric potential for an electric field (and thus for an emf) that is induced by a changing magnetic flux. This means that when a self-induced emf is produced in the inductor of Fig. 30-13, we cannot define an electric potential within the inductor itself, where the flux is changing. However, potentials can still be defined at points of the circuit that are not within the inductor—points where the electric fields are due to charge distributions and their associated electric potentials.

Moreover, we can define a self-induced potential difference \( V_L \) across an inductor (between its terminals, which we assume to be outside the region of changing flux). For an ideal inductor (its wire has negligible resistance), the magnitude of \( V_L \) is equal to the magnitude of the self-induced emf \( \xi_L \).

If, instead, the wire in the inductor has resistance \( r \), we mentally separate the inductor into a resistance \( r \) (which we take to be outside the region of changing flux) and an ideal inductor of self-induced emf \( \xi_L \). As with a real battery of emf \( \xi \) and internal resistance \( r \), the potential difference across the terminals of a real inductor then differs from the emf. Unless otherwise indicated, we assume here that inductors are ideal.

**Checkpoint 5**

The figure shows an emf \( \xi_L \) induced in a coil. Which of the following can describe the current through the coil:
(a) constant and rightward, (b) constant and leftward, (c) increasing and rightward, (d) decreasing and rightward, (e) increasing and leftward, (f) decreasing and leftward?

### 30-6 RL Circuits

#### Learning Objectives

After reading this module, you should be able to . . .

30.25 Sketch a schematic diagram of an RL circuit in which the current is rising.
30.26 Write a loop equation (a differential equation) for an RL circuit in which the current is rising.
30.27 For an RL circuit in which the current is rising, apply the equation \( i(t) \) for the current as a function of time.
30.28 For an RL circuit in which the current is rising, find equations for the potential difference \( V \) across the resistor, the rate \( di/dt \) at which current changes, and the emf of the inductor, as functions of time.
30.29 Calculate an inductive time constant \( \tau_L \).
30.30 Sketch a schematic diagram of an RL circuit in which the current is decaying.

30.31 Write a loop equation (a differential equation) for an RL circuit in which the current is decaying.
30.32 For an RL circuit in which the current is decaying, apply the equation \( i(t) \) for the current as a function of time.
30.33 From an equation for decaying current in an RL circuit, find equations for the potential difference \( V \) across the resistor, the rate \( di/dt \) at which current is changing, and the emf of the inductor, as functions of time.
30.34 For an RL circuit, identify the current through the inductor and the emf across it just as current in the circuit begins to change (the initial condition) and a long time later when equilibrium is reached (the final condition).

#### Key Ideas

- If a constant emf \( \xi \) is introduced into a single-loop circuit containing a resistance \( R \) and an inductance \( L \), the current rises to an equilibrium value of \( \xi/R \) according to
  \[
i = \frac{\xi}{R} \left(1 - e^{-t/\tau_L}\right) \quad \text{(rise of current)}.
\]
  Here \( \tau_L = L/R \) governs the rate of rise of the current and is called the inductive time constant of the circuit.

- When the source of constant emf is removed, the current decays from a value \( i_0 \) according to
  \[
i = i_0 e^{-t/\tau_L} \quad \text{(decay of current)}.
\]
**RL Circuits**

In Module 27-4 we saw that if we suddenly introduce an emf $\mathcal{E}$ into a single-loop circuit containing a resistor $R$ and a capacitor $C$, the charge on the capacitor does not build up immediately to its final equilibrium value $C\mathcal{E}$ but approaches it in an exponential fashion:

$$q = C\mathcal{E}(1 - e^{-\frac{t}{\tau_C}}).$$  \hfill (30-36)

The rate at which the charge builds up is determined by the capacitive time constant $\tau_C$, defined in Eq. 27-36 as

$$\tau_C = RC.$$  \hfill (30-37)

If we suddenly remove the emf from this same circuit, the charge does not immediately fall to zero but approaches zero in an exponential fashion:

$$q = q_0e^{-\frac{t}{\tau_C}}.$$  \hfill (30-38)

The time constant $\tau_C$ describes the fall of the charge as well as its rise.

An analogous slowing of the rise (or fall) of the current occurs if we introduce an emf $\mathcal{E}$ into (or remove it from) a single-loop circuit containing a resistor $R$ and an inductor $L$. When the switch $S$ in Fig. 30-15 is closed on $a$, for example, the current in the resistor starts to rise. If the inductor were not present, the current would rise rapidly to a steady value $\mathcal{E}/R$. Because of the inductor, however, a self-induced emf $\mathcal{E}_L$ appears in the circuit; from Lenz’s law, this emf opposes the rise of the current, which means that it opposes the battery emf $\mathcal{E}$ in polarity. Thus, the current in the resistor responds to the difference between two emfs, a constant $\mathcal{E}$ due to the battery and a variable $\mathcal{E}_L (= -L\frac{di}{dt})$ due to self-induction. As long as this $\mathcal{E}_L$ is present, the current will be less than $\mathcal{E}/R$.

As time goes on, the rate at which the current increases becomes less rapid and the magnitude of the self-induced emf, which is proportional to $\frac{di}{dt}$, becomes smaller. Thus, the current in the circuit approaches $\mathcal{E}/R$ asymptotically.

We can generalize these results as follows:

Initially, an inductor acts to oppose changes in the current through it. A long time later, it acts like ordinary connecting wire.

Now let us analyze the situation quantitatively. With the switch $S$ in Fig. 30-15 thrown to $a$, the circuit is equivalent to that of Fig. 30-16. Let us apply the loop rule, starting at point $x$ in this figure and moving clockwise around the loop along with current $i$.

1. **Resistor.** Because we move through the resistor in the direction of current $i$, the electric potential decreases by $iR$. Thus, as we move from point $x$ to point $y$, we encounter a potential change of $-iR$.

2. **Inductor.** Because current $i$ is changing, there is a self-induced emf $\mathcal{E}_L$ in the inductor. The magnitude of $\mathcal{E}_L$ is given by Eq. 30-35 as $L\frac{di}{dt}$. The direction of $\mathcal{E}_L$ is upward in Fig. 30-16 because current $i$ is downward through the inductor and increasing. Thus, as we move from point $y$ to point $z$, opposite the direction of $\mathcal{E}_L$, we encounter a potential change of $-L\frac{di}{dt}$.

3. **Battery.** As we move from point $z$ back to starting point $x$, we encounter a potential change of $+\mathcal{E}$ due to the battery’s emf.

Thus, the loop rule gives us

$$-iR - L\frac{di}{dt} + \mathcal{E} = 0$$

Figure 30-15 An RL circuit. When switch $S$ is closed on $a$, the current rises and approaches a limiting value $\mathcal{E}/R$.

Figure 30-16 The circuit of Fig. 30-15 with the switch closed on $a$. We apply the loop rule for the circuit clockwise, starting at $x$. 

\[30-6 \text{ RL CIRCUITS} \]
Equation 30-39 is a differential equation involving the variable \( i \) and its first derivative \( di/dt \). To solve it, we seek the function \( i(t) \) such that when \( i(t) \) and its first derivative are substituted in Eq. 30-39, the equation is satisfied and the initial condition \( i(0) = 0 \) is satisfied.

Equation 30-39 and its initial condition are of exactly the form of Eq. 27-32 for an \( RC \) circuit, with \( i \) replacing \( q \), \( L \) replacing \( R \), and \( R \) replacing \( 1/C \). The solution of Eq. 30-39 must then be of exactly the form of Eq. 27-33 with the same replacements. That solution is

\[
i = \frac{\xi}{R} \left(1 - e^{-Rt/L}\right),
\]

which we can rewrite as

\[
i = \frac{\xi}{R} \left(1 - e^{-\tau_L} \right) \quad \text{(rise of current)}. \tag{30-41}
\]

Here \( \tau_L \), the **inductive time constant**, is given by

\[
\tau_L = \frac{L}{R} \quad \text{(time constant)}. \tag{30-42}
\]

Let’s examine Eq. 30-41 for just after the switch is closed (at time \( t = 0 \)) and for a time long after the switch is closed (\( t \to \infty \)). If we substitute \( t = 0 \) into Eq. 30-41, the exponential becomes \( e^{-0} = 1 \). Thus, Eq. 30-41 tells us that the current is initially \( i = 0 \), as we expected. Next, if we let \( t \) go to \( \infty \), then the exponential goes to \( e^{-\infty} = 0 \). Thus, Eq. 30-41 tells us that the current goes to its equilibrium value of \( \xi/R \).

We can also examine the potential differences in the circuit. For example, Fig. 30-17 shows how the potential differences \( V_R (= iR) \) across the resistor and \( V_L (= L \, di/dt) \) across the inductor vary with time for particular values of \( \xi \), \( L \), and \( R \). Compare this figure carefully with the corresponding figure for an \( RC \) circuit (Fig. 27-16).

**Figure 30-17** The variation with time of (a) \( V_R \), the potential difference across the resistor in the circuit of Fig. 30-16, and (b) \( V_L \), the potential difference across the inductor in that circuit. The small triangles represent successive intervals of one inductive time constant \( \tau_L = L/R \). The figure is plotted for \( R = 2000 \, \Omega \), \( L = 4.0 \, \text{H} \), and \( \xi = 10 \, \text{V} \).
To show that the quantity \( \tau_L = \frac{L}{R} \) has the dimension of time (as it must, because the argument of the exponential function in Eq. 30-41 must be dimensionless), we convert from henries per ohm as follows:

\[
\frac{1}{\Omega} \left( \frac{1}{H} \right) = \frac{1}{\Omega} \left( \frac{1 \text{ V} \cdot \text{s}}{1 \text{ H} \cdot \text{A}} \right) = \frac{1 \text{ V}}{1 \text{ A}} = 1 \text{ s}.
\]

The first quantity in parentheses is a conversion factor based on Eq. 30-35, and the second one is a conversion factor based on the relation \( V = iR \).

**Time Constant.** The physical significance of the time constant follows from Eq. 30-41. If we put \( t_L = \frac{L}{R} \) in this equation, it reduces to

\[
i = \frac{\mathcal{E}}{R} \left(1 - e^{-1}\right) = 0.63 \frac{\mathcal{E}}{R}.
\]

Thus, the time constant \( \tau_L \) is the time it takes the current in the circuit to reach about 63% of its final equilibrium value \( \mathcal{E}/R \). Since the potential difference \( V_R \) across the resistor is proportional to the current \( i \), a graph of the increasing current versus time has the same shape as that of \( V_R \) in Fig. 30-17a.

**Current Decay.** If the switch S in Fig. 30-15 is closed on a long enough for the equilibrium current \( \mathcal{E}/R \) to be established and then is thrown to \( b \), the effect will be to remove the battery from the circuit. (The connection to \( b \) must actually be made an instant before the connection to \( a \) is broken. A switch that does this is called a make-before-break switch.) With the battery gone, the current through the resistor will decrease. However, it cannot drop immediately to zero but must decay to zero over time. The differential equation that governs the decay can be found by putting \( \mathcal{E} = 0 \) in Eq. 30-39:

\[
L \frac{di}{dt} + iR = 0.
\]

By analogy with Eqs. 27-38 and 27-39, the solution of this differential equation that satisfies the initial condition \( i(0) = i_0 = \mathcal{E}/R \) is

\[
i = \frac{\mathcal{E}}{R} e^{-\frac{R}{L}t} = i_0 e^{-\frac{R}{L}t} \quad \text{(decay of current)}.
\]

We see that both current rise (Eq. 30-41) and current decay (Eq. 30-45) in an RL circuit are governed by the same inductive time constant, \( \tau_L \).

We have used \( i_0 \) in Eq. 30-45 to represent the current at time \( t = 0 \). In our case that happened to be \( \mathcal{E}/R \), but it could be any other initial value.

**Checkpoint 6**

The figure shows three circuits with identical batteries, inductors, and resistors. Rank the circuits according to the current through the battery (a) just after the switch is closed and (b) a long time later, greatest first. (If you have trouble here, work through the next sample problem and then try again.)
**Sample Problem 30.05  RL circuit, immediately after switching and after a long time**

Figure 30-18a shows a circuit that contains three identical resistors with resistance \( R = 9.0 \, \Omega \), two identical inductors with inductance \( L = 2.0 \, \text{mH} \), and an ideal battery with emf \( \mathcal{E} = 18 \, \text{V} \).

(a) What is the current \( i \) through the battery just after the switch is closed?

**KEY IDEA**

Just after the switch is closed, the inductor acts to oppose a change in the current through it.

**Calculations:** Because the current through each inductor is zero before the switch is closed, it will also be zero just afterward. Thus, immediately after the switch is closed, the inductors act as broken wires, as indicated in Fig. 30-18b. We then have a single-loop circuit for which the loop rule gives us

\[
\mathcal{E} - i R = 0.
\]

Substituting given data, we find that

\[
i = \frac{\mathcal{E}}{R} = \frac{18 \, \text{V}}{9.0 \, \Omega} = 2.0 \, \text{A}. \quad \text{(Answer)}
\]

(b) What is the current \( i \) through the battery long after the switch has been closed?

**KEY IDEA**

Long after the switch has been closed, the currents in the circuit have reached their equilibrium values, and the inductors act as simple connecting wires, as indicated in Fig. 30-18c.

**Calculations:** We now have a circuit with three identical resistors in parallel; from Eq. 27-23, their equivalent resistance is \( R_{eq} = R/3 = (9.0 \, \Omega)/3 = 3.0 \, \Omega \). The equivalent circuit shown in Fig. 30-18d then yields the loop equation \( \mathcal{E} - i R_{eq} = 0 \), or

\[
i = \frac{\mathcal{E}}{R_{eq}} = \frac{18 \, \text{V}}{3.0 \, \Omega} = 6.0 \, \text{A}. \quad \text{(Answer)}
\]

**Sample Problem 30.06  RL circuit, current during the transition**

A solenoid has an inductance of 53 mH and a resistance of 0.37 \( \Omega \). If the solenoid is connected to a battery, how long will the current take to reach half its final equilibrium value? (This is a real solenoid because we are considering its small, but nonzero, internal resistance.)

**KEY IDEA**

We can mentally separate the solenoid into a resistance and an inductance that are wired in series with a battery, as in Fig. 30-16. Then application of the loop rule leads to Eq. 30-39, which has the solution of Eq. 30-41 for the current \( i \) in the circuit.

**Calculations:** According to that solution, current \( i \) increases exponentially from zero to its final equilibrium value of \( \mathcal{E}/R \). Let \( t_0 \) be the time that current \( i \) takes to reach half its equilibrium value. Then Eq. 30-41 gives us

\[
\frac{1}{2} \frac{\mathcal{E}}{R} = \frac{\mathcal{E}}{R} (1 - e^{-t_0/\tau_i}).
\]

We solve for \( t_0 \) by canceling \( \mathcal{E}/R \), isolating the exponential, and taking the natural logarithm of each side. We find

\[
t_0 = \tau_i \ln 2 = \frac{L}{R} \ln 2 = \frac{53 \times 10^{-3} \, \text{H}}{0.37 \, \Omega} \ln 2 = 0.10 \, \text{s}. \quad \text{(Answer)}
\]
ENERGY STORED IN A MAGNETIC FIELD

30-7

Learning Objectives

After reading this module, you should be able to . . .

30.35 Describe the derivation of the equation for the magnetic field energy of an inductor in an RL circuit with a constant emf source.

30.36 For an inductor in an RL circuit, apply the relationship between the magnetic field energy \( U_B \), the inductance \( L \), and the current \( i \).

Key Idea

- If an inductor \( L \) carries a current \( i \), the inductor’s magnetic field stores an energy given by

\[
U_B = \frac{1}{2} Li^2 \quad \text{(magnetic energy)}.
\]

Energy Stored in a Magnetic Field

When we pull two charged particles of opposite signs away from each other, we say that the resulting electric potential energy is stored in the electric field of the particles. We get it back from the field by letting the particles move closer together again. In the same way we say energy is stored in a magnetic field, but now we deal with current instead of electric charges.

To derive a quantitative expression for that stored energy, consider again Fig. 30-16, which shows a source of emf \( \mathcal{E} \) connected to a resistor \( R \) and an inductor \( L \). Equation 30-39, restated here for convenience,

\[
\mathcal{E} = L \frac{di}{dt} + iR,
\]

is the differential equation that describes the growth of current in this circuit. Recall that this equation follows immediately from the loop rule and that the loop rule in turn is an expression of the principle of conservation of energy for single-loop circuits. If we multiply each side of Eq. 30-46 by \( i \), we obtain

\[
\mathcal{E} i = Li \frac{di}{dt} + i^2 R,
\]

which has the following physical interpretation in terms of the work done by the battery and the resulting energy transfers:

1. If a differential amount of charge \( dq \) passes through the battery of emf \( \mathcal{E} \) in Fig. 30-16 in time \( dt \), the battery does work on it in the amount \( \mathcal{E} dq \). The rate at which the battery does work is \( (\mathcal{E} dq)/dt \), or \( \mathcal{E} i \). Thus, the left side of Eq. 30-47 represents the rate at which the emf device delivers energy to the rest of the circuit.

2. The rightmost term in Eq. 30-47 represents the rate at which energy appears as thermal energy in the resistor.

3. Energy that is delivered to the circuit but does not appear as thermal energy must, by the conservation-of-energy hypothesis, be stored in the magnetic field of the inductor. Because Eq. 30-47 represents the principle of conservation of energy for RL circuits, the middle term must represent the rate \( dU_B/dt \) at which magnetic potential energy \( U_B \) is stored in the magnetic field.

Thus

\[
\frac{dU_B}{dt} = Li \frac{di}{dt}.
\]
We can write this as
\[ dU_B = Li \, di. \]
Integrating yields
\[ \int_0^t dU_B = \int_0^i Li \, di \]
or
\[ U_B = \frac{1}{2} Li^2 \quad \text{(magnetic energy),} \quad (30-49) \]
which represents the total energy stored by an inductor \( L \) carrying a current \( i \).

Note the similarity in form between this expression for the energy stored in a magnetic field and the expression for the energy stored in an electric field by a capacitor with capacitance \( C \) and charge \( q \); namely,
\[ U_E = \frac{q^2}{2C}. \quad (30-50) \]
(The variable \( i^2 \) corresponds to \( q^2 \), and the constant \( L \) corresponds to \( 1/C \).)

---

**Sample Problem 30.07 Energy stored in a magnetic field**

A coil has an inductance of 53 mH and a resistance of 0.35 Ω.

(a) If a 12 V emf is applied across the coil, how much energy is stored in the magnetic field after the current has built up to its equilibrium value?

**KEY IDEA**

The energy stored in the magnetic field of a coil at any time depends on the current through the coil at that time, according to Eq. 30-49 \( U_B = \frac{1}{2} Li^2 \).

**Calculations:** Thus, to find the energy \( U_B \) stored at equilibrium, we must first find the equilibrium current. From Eq. 30-41, the equilibrium current is
\[ i_e = \frac{\varepsilon}{R} = \frac{12 \, \text{V}}{0.35 \, \Omega} = 34.3 \, \text{A.} \quad (30-51) \]
Then substitution yields
\[ U_B = \frac{1}{2} Li_e^2 = \left(\frac{1}{2}\right)(53 \times 10^{-3} \, \text{H})(34.3 \, \text{A})^2 = 31 \, \text{J.} \quad \text{(Answer)} \]

(b) After how many time constants will half this equilibrium energy be stored in the magnetic field?

**Calculations:** Now we are being asked: At what time \( t \) will the relation
\[ U_B = \frac{1}{2} U_{B=} \]
be satisfied? Using Eq. 30-49 twice allows us to rewrite this energy condition as
\[ \frac{1}{2} Li^2 = \left(\frac{1}{2}\right)\frac{1}{2} Li_e^2 \]
or
\[ i = \left(\frac{1}{\sqrt{2}}\right)i_e. \quad (30-52) \]
This equation tells us that, as the current increases from its initial value of 0 to its final value of \( i_e \), the magnetic field will have half its final stored energy when the current has increased to this value. In general, we know that \( i \) is given by Eq. 30-41, and here \( i_e \) (see Eq. 30-51) is \( \varepsilon/R \); so Eq. 30-52 becomes
\[ \frac{\varepsilon}{R} \left(1 - e^{-\nu t}\right) = \frac{\varepsilon}{\sqrt{2}R}. \]
By canceling \( \varepsilon/R \) and rearranging, we can write this as
\[ e^{-\nu t} = 1 - \frac{1}{\sqrt{2}} = 0.293, \]
which yields
\[ \frac{t}{\tau_L} = -\ln 0.293 = 1.23 \]
or
\[ t = 1.2\tau_L. \quad \text{(Answer)} \]
Thus, the energy stored in the magnetic field of the coil by the current will reach half its equilibrium value 1.2 time constants after the emf is applied.
**30-8 ENERGY DENSITY OF A MAGNETIC FIELD**

**Learning Objectives**

*After reading this module, you should be able to . . .*

- **30.37** Identify that energy is associated with any magnetic field.
- **30.38** Apply the relationship between energy density \( u_B \) of a magnetic field and the magnetic field magnitude \( B \).

**Key Idea**

- If \( B \) is the magnitude of a magnetic field at any point (in an inductor or anywhere else), the density of stored magnetic energy at that point is

\[
    u_B = \frac{B^2}{2\mu_0} \quad \text{(magnetic energy density)}.\]

**Energy Density of a Magnetic Field**

Consider a length \( l \) near the middle of a long solenoid of cross-sectional area \( A \) carrying current \( i \); the volume associated with this length is \( Al \). The energy \( U_B \) stored by the length \( l \) of the solenoid must lie entirely within this volume because the magnetic field outside such a solenoid is approximately zero. Moreover, the stored energy must be uniformly distributed within the solenoid because the magnetic field is (approximately) uniform everywhere inside.

Thus, the energy stored per unit volume of the field is

\[
    u_B = \frac{U_B}{Al} \quad \text{(magnetic energy density)}.\]

or, since

\[
    U_B = \frac{1}{2} Li^2, \]

we have

\[
    u_B = \frac{Ll^2}{2Al} = \frac{L}{I} \frac{i^2}{2A}. \quad (30-53)
\]

Here \( L \) is the inductance of length \( l \) of the solenoid.

Substituting for \( L/l \) from Eq. 30-31, we find

\[
    u_B = \frac{1}{2}\mu_0 n^2 i^2, \quad (30-54)
\]

where \( n \) is the number of turns per unit length. From Eq. 29-23 (\( B = \mu_0 n i \)) we can write this energy density as

\[
    u_B = \frac{B^2}{2\mu_0} \quad \text{(magnetic energy density)}. \quad (30-55)
\]

This equation gives the density of stored energy at any point where the magnitude of the magnetic field is \( B \). Even though we derived it by considering the special case of a solenoid, Eq. 30-55 holds for all magnetic fields, no matter how they are generated. The equation is comparable to Eq. 25-25,

\[
    u_E = \frac{1}{2}\varepsilon_0 E^2, \quad (30-56)
\]

which gives the energy density (in a vacuum) at any point in an electric field. Note that both \( u_B \) and \( u_E \) are proportional to the square of the appropriate field magnitude, \( B \) or \( E \).
Mutual Induction

In this section we return to the case of two interacting coils, which we first discussed in Module 30-1, and we treat it in a somewhat more formal manner. We saw earlier that if two coils are close together as in Fig. 30-2, a steady current \( i \) in one coil will set up a magnetic flux \( \Phi \) through the other coil (linking the other coil). If we change \( i \) with time, an emf \( \mathcal{E} \) given by Faraday’s law appears in the second coil; we called this process induction. We could better have called it mutual induction, to suggest the mutual interaction of the two coils and to distinguish it from self-induction, in which only one coil is involved.

Let us look a little more quantitatively at mutual induction. Figure 30-19a shows two circular close-packed coils near each other and sharing a common central axis. With the variable resistor set at a particular resistance \( R \), the battery produces a steady current \( i_1 \) in coil 1. This current creates a magnetic field represented by the lines of \( \mathbf{B}_1 \) in the figure. Coil 2 is connected to a sensitive meter but contains no battery; a magnetic flux \( \Phi_{21} \) (the flux through coil 2 associated with the current in coil 1) links the \( N_2 \) turns of coil 2.

We define the mutual inductance \( M_{21} \) of coil 2 with respect to coil 1 as

\[
M_{21} = \frac{N_2 \Phi_{21}}{i_1},
\]  

(30-57)
which has the same form as Eq. 30-28,

\[ L = N \Phi i, \quad (30-58) \]

the definition of inductance. We can recast Eq. 30-57 as

\[ M_{21}i_1 = N_2 \Phi_{21}. \quad (30-59) \]

If we cause \( i_1 \) to vary with time by varying \( R \), we have

\[ M_{21} \frac{di_1}{dt} = N_2 \frac{d\Phi_{21}}{dt}. \quad (30-60) \]

The right side of this equation is, according to Faraday’s law, just the magnitude of the emf \( \mathcal{E}_2 \) appearing in coil 2 due to the changing current in coil 1. Thus, with a minus sign to indicate direction,

\[ \mathcal{E}_2 = -M_{21} \frac{di_1}{dt}, \quad (30-61) \]

which you should compare with Eq. 30-35 for self-induction (\( \mathcal{E} = -L \frac{di}{dt} \)).

**Interchange.** Let us now interchange the roles of coils 1 and 2, as in Fig. 30-19b; that is, we set up a current \( i_2 \) in coil 2 by means of a battery, and this produces a magnetic flux \( \Phi_{12} \) that links coil 1. If we change \( i_2 \) with time by varying \( R \), we then have, by the argument given above,

\[ \mathcal{E}_1 = -M_{12} \frac{di_2}{dt}. \quad (30-62) \]

Thus, we see that the emf induced in either coil is proportional to the rate of change of current in the other coil. The proportionality constants \( M_{21} \) and \( M_{12} \) seem to be different. However, they turn out to be the same, although we cannot prove that fact here. Thus, we have

\[ M_{21} = M_{12} = M, \quad (30-63) \]

and we can rewrite Eqs. 30-61 and 30-62 as

\[ \mathcal{E}_2 = -M \frac{di_1}{dt}, \quad (30-64) \]

and

\[ \mathcal{E}_1 = -M \frac{di_2}{dt}. \quad (30-65) \]
Sample Problem 30.08  Mutual inductance of two parallel coils

Figure 30-20 shows two circular close-packed coils, the smaller (radius $R_2$, with $N_2$ turns) being coaxial with the larger (radius $R_1$, with $N_1$ turns) and in the same plane.

(a) Derive an expression for the mutual inductance $M$ for this arrangement of these two coils, assuming that $R_1 \gg R_2$.

**KEY IDEA**

The mutual inductance $M$ for these coils is the ratio of the flux linkage ($N\Phi$) through one coil to the current $i$ in the other coil, which produces that flux linkage. Thus, we need to assume that currents exist in the coils; then we need to calculate the flux linkage in one of the coils.

**Calculations:** The magnetic field through the larger coil due to the smaller coil is nonuniform in both magnitude and direction; so the flux through the larger coil due to the smaller coil is nonuniform in both magnitude and direction; thus, the flux through one coil to the current $i$ in the other coil, which produces that flux linkage. Thus, we need to assume that currents exist in the coils; then we need to calculate the flux linkage in one of the coils.

Substituting Eq. 30-68 for $B_1$ and $\pi R_2^2$ for $A_2$ in Eq. 30-67 yields

$$M = \frac{N_2\Phi_{21}}{i_1}$$

$$N_2\Phi_{21} = \frac{\pi\mu_0 N_1 N_2 R_2^2 i_1}{2R_1}.$$  

Substituting this result into Eq. 30-66, we find

$$M = \frac{N_2\Phi_{21}}{i_1} = \frac{\pi\mu_0 N_1 N_2 R_2^2 \pi R_2}{2R_1}.$$  

(Answer) (30-69)

(b) What is the value of $M$ for $N_1 = N_2 = 1200$ turns, $R_2 = 1.1$ cm, and $R_1 = 15$ cm?

**Calculations:** Equation 30-69 yields

$$M = \frac{(\pi)(4\pi \times 10^{-7} \text{ H/m})(1200)(1200)(0.011 \text{ m})^2}{(2)(0.15 \text{ m})}$$

$$= 2.29 \times 10^{-3} \text{ H} \approx 2.3 \text{ mH.}$$  

(Answer)

Consider the situation if we reverse the roles of the two coils—that is, if we produce a current $i_2$ in the smaller coil and try to calculate $M$ from Eq. 30-57 in the form

$$M = \frac{N_1\Phi_{12}}{i_2}.$$  

The calculation of $\Phi_{12}$ (the nonuniform flux of the smaller coil’s magnetic field encompassed by the larger coil) is not simple. If we were to do the calculation numerically using a computer, we would find $M$ to be $2.3 \text{ mH}$, as above! This emphasizes that Eq. 30-63 ($M_{21} = M_{12} = M$) is not obvious.
**Review & Summary**

**Magnetic Flux** The magnetic flux $\Phi_B$ through an area $A$ in a magnetic field $\vec{B}$ is defined as

$$\Phi_B = \int \vec{B} \cdot d\vec{A}, \quad (30-1)$$

where the integral is taken over the area. The SI unit of magnetic flux is the weber, where $1 \text{ Wb} = 1 \text{T} \cdot \text{m}^2$. If $\vec{B}$ is perpendicular to the area and uniform over it, Eq. 30-1 becomes

$$\Phi_B = BA \quad (\vec{B} \perp A, B \text{ uniform}). \quad (30-2)$$

**Faraday’s Law of Induction** If the magnetic flux $\Phi_B$ through an area bounded by a closed conducting loop changes with time, a current and an emf are produced in the loop; this process is called induction. The induced emf is

$$\mathcal{E} = -\frac{d\Phi_B}{dt} \quad (\text{Faraday’s law}). \quad (30-4)$$

If the loop is replaced by a closely packed coil of $N$ turns, the induced emf is

$$\mathcal{E} = -N \frac{d\Phi_B}{dt} \quad (30-5)$$

**Lenz’s Law** An induced current has a direction such that the magnetic field due to the current opposes the change in the magnetic flux that induces the current. The induced emf has the same direction as the induced current.

**Emf and the Induced Electric Field** An emf is induced by a changing magnetic flux even if the loop through which the flux is changing is not a physical conductor but an imaginary line. The changing magnetic field induces an electric field $\vec{E}$ at every point of such a loop; the induced emf is related to $\vec{E}$ by

$$\mathcal{E} = \oint \vec{E} \cdot d\vec{s}, \quad (30-19)$$

where the integration is taken around the loop. From Eq. 30-19 we can write Faraday’s law in its most general form,

$$\oint \vec{E} \cdot d\vec{s} = -\frac{d\Phi_B}{dt} \quad (\text{Faraday’s law}). \quad (30-20)$$

A changing magnetic field induces an electric field $\vec{E}$.

**Inductors** An inductor is a device that can be used to produce a known magnetic field in a specified region. If a current $i$ is established through each of the $N$ windings of an inductor, a magnetic flux $\Phi_B$ links those windings. The inductance $L$ of the inductor is

$$L = \frac{N\Phi_B}{i} \quad (\text{inductance defined}). \quad (30-28)$$

The SI unit of inductance is the henry (H), where $1 \text{ H} = 1 \text{T} \cdot \text{m}^2/\text{A}$. The inductance per unit length near the middle of a long solenoid of cross-sectional area $A$ and $n$ turns per unit length is

$$\frac{L}{l} = \mu_0 n^2 A \quad (\text{solenoid}). \quad (30-31)$$

**Self-Induction** If a current $i$ in a coil changes with time, an emf is induced in the coil. This self-induced emf is

$$\mathcal{E}_L = -L \frac{di}{dt}. \quad (30-35)$$

The direction of $\mathcal{E}_L$ is found from Lenz’s law: The self-induced emf acts to oppose the change that produces it.

**Series RL Circuits** If a constant emf $\mathcal{E}$ is introduced into a single-loop circuit containing a resistance $R$ and an inductance $L$, the current rises to an equilibrium value of $\mathcal{E}/R$:

$$i = \frac{\mathcal{E}}{R} \left(1 - e^{-t/\tau_L}\right) \quad (\text{rise of current}). \quad (30-41)$$

Here $\tau_L = (L/R)$ is the inductive time constant. When the source of constant emf is removed, the current decays from a value $i_0$ according to

$$i = i_0 e^{-t/\tau_L} \quad (\text{decay of current}). \quad (30-45)$$

**Magnetic Energy** If an inductor $L$ carries a current $i$, the inductor’s magnetic field stores an energy given by

$$U_B = \frac{1}{2} Li^2 \quad (\text{magnetic energy}). \quad (30-49)$$

If $B$ is the magnitude of a magnetic field at any point (in an inductor or anywhere else), the density of stored magnetic energy at that point is

$$u_B = \frac{B^2}{2\mu_0} \quad (\text{magnetic energy density}). \quad (30-55)$$

**Mutual Induction** If coils 1 and 2 are near each other, a changing current in either coil can induce an emf in the other. This mutual induction is described by

$$\mathcal{E}_2 = -M \frac{di_1}{dt} \quad (30-64)$$

and

$$\mathcal{E}_1 = -M \frac{di_2}{dt}, \quad (30-65)$$

where $M$ (measured in henries) is the mutual inductance.

**Questions**

1. If the circular conductor in Fig. 30-21 undergoes thermal expansion while it is in a uniform magnetic field, a current is induced clockwise around it. Is the magnetic field directed into or out of the page?

2. The wire loop in Fig. 30-22a is subjected, in turn, to six uniform magnetic fields, each directed parallel to the $z$-axis. Figure 30-21 Question 1.

![Figure 30-21](attachment:image1.png)

Figure 30-21 Question 1.

![Figure 30-22](attachment:image2.png)

Figure 30-22 Question 2.
axis, which is directed out of the plane of the figure. Figure 30-22b gives the $z$ components $B_z$ of the fields versus time $t$. (Plots 1 and 3 are parallel; so are plots 4 and 6. Plots 2 and 5 are parallel to the time axis.) Rank the six plots according to the emf induced in the loop, greatest clockwise emf first, greatest counterclockwise emf last.

3 In Fig. 30-23, a long straight wire with current $i$ passes (without touching) three rectangular wire loops with edge lengths $L_1$, $1.5L_1$, and $2L_1$. The loops are widely spaced (so as not to affect one another). Loops 1 and 3 are symmetric about the long wire. Rank the loops according to the size of the current induced in them if current $i$ is (a) constant and (b) increasing, greatest first.

![Figure 30-23 Question 3.](image)

4 Figure 30-24 shows two circuits in which a conducting bar is slid at the same speed $v$ through the same uniform magnetic field and along a U-shaped wire. The parallel lengths of the wire are separated by $2L$ in circuit 1 and by $L$ in circuit 2. The current induced in circuit 1 is counterclockwise. (a) Is the magnetic field into or out of the page? (b) Is the current induced in circuit 2 clockwise or counterclockwise? (c) Is the emf induced in circuit 1 larger than, smaller than, or the same as that in circuit 2?

![Figure 30-24 Question 4.](image)

5 Figure 30-25 shows a circular region in which a decreasing uniform magnetic field is directed out of the page, as well as four concentric circular paths. Rank the paths according to the magnitude of $\oint \vec{E} \cdot d\vec{s}$ evaluated along them, greatest first.

![Figure 30-25 Question 5.](image)

6 In Fig. 30-26, a wire loop has been bent so that it has three segments: segment $bc$ (a quarter-circle), $ac$ (a square corner), and $ab$ (straight). Here are three choices for a magnetic field through the loop:

- (1) $\vec{B}_1 = 3\hat{i} + 7\hat{j} - 5\hat{k}$,
- (2) $\vec{B}_2 = 5\hat{i} - 4\hat{j} - 15\hat{k}$,
- (3) $\vec{B}_3 = 2\hat{i} - 5\hat{j} - 12\hat{k}$,

where $\vec{B}$ is in milliteslas and $t$ is in seconds. Without written calculation, rank the choices according to (a) the work done per unit charge in setting up the induced current and (b) that induced current, greatest first. (c) For each choice, what is the direction of the induced current in the figure?

![Figure 30-26 Question 6.](image)

7 Figure 30-27 shows a circuit with two identical resistors and an ideal inductor. Is the current through the central resistor more than, less than, or the same as that through the other resistor (a) just after the closing of switch $S$, (b) a long time after that, (c) just after $S$ is reopened a long time later, and (d) a long time after that?

![Figure 30-27 Question 7.](image)

8 The switch in the circuit of Fig. 30-15 has been closed on $a$ for a very long time when it is then thrown to $b$. The resulting current through the inductor is indicated in Fig. 30-28 for four sets of values for the resistance $R$ and inductance $L$: (1) $R_0$ and $L_v$, (2) $2R_0$ and $L_v$, (3) $R_0$ and $2L_v$, (4) $2R_0$ and $2L_v$. Which set goes with which curve?

![Figure 30-28 Question 8.](image)

9 Figure 30-29 shows three circuits with identical batteries, inductors, and resistors. Rank the circuits, greatest first, according to the current through the resistor labeled $R$ (a) long after the switch is closed, (b) just after the switch is reopened a long time later, and (c) long after it is reopened.

![Figure 30-29 Question 9.](image)

10 Figure 30-30 gives the variation with time of the potential difference $V_R$ across a resistor in three circuits wired as shown in Fig. 30-16. The circuits contain the same resistance $R$ and emf $\varepsilon$ but differ in the inductance $L$. Rank the circuits according to the value of $L$, greatest first.

![Figure 30-30 Question 10.](image)
11 Figure 30-31 shows three situations in which a wire loop lies partially in a magnetic field. The magnitude of the field is either increasing or decreasing, as indicated. In each situation, a battery is part of the loop. In which situations are the induced emf and the battery emf in the same direction along the loop?

![Figure 30-31](image)

(a) increasing (b) decreasing (c) decreasing

Figure 30-31 Question 11.

12 Figure 30-32 gives four situations in which we pull rectangular wire loops out of identical magnetic fields (directed into the page) at the same constant speed. The loops have edge lengths of either L or 2L, as drawn. Rank the situations according to (a) the magnitude of the force required of us and (b) the rate at which energy is transferred from us to thermal energy of the loop, greatest first.

![Figure 30-32](image)

(1) (2) (3) (4)

Figure 30-32 Question 12.

**Module 30-1 Faraday’s Law and Lenz’s Law**

1 In Fig. 30-33, a circular loop of wire 10 cm in diameter (seen edge-on) is placed with its normal $\mathbf{N}$ at an angle $\theta = 30^\circ$ with the direction of a uniform magnetic field $\mathbf{B}$ of magnitude 0.50 T. The loop is then rotated such that $\mathbf{N}$ rotates in a cone about the field direction at the rate 100 rev/min; angle $\theta$ remains unchanged during the process. What is the emf induced in the loop?

![Figure 30-33](image)

Figure 30-33 Problem 1.

2 A certain elastic conducting material is stretched into a circular loop of 12.0 cm radius. It is placed with its plane perpendicular to a uniform 0.800 T magnetic field. When released, the radius of the loop starts to shrink at an instantaneous rate of 75.0 cm/s. What emf is induced in the loop at that instant?

![Figure 30-34](image)

Figure 30-34 Problem 3.

3 **SSM** WWW In Fig. 30-34, a 120-turn coil of radius 1.8 cm and resistance 5.3 $\Omega$ is coaxial with a solenoid of 220 turns/cm and diameter 3.2 cm. The solenoid current drops from 1.5 A to zero in time interval $\Delta t = 25$ ms. What current is induced in the coil during $\Delta t$?

![Figure 30-35](image)

Figure 30-35 Problem 4.

4 A wire loop of radius 12 cm and resistance 8.5 $\Omega$ is located in a uniform magnetic field $\mathbf{B}$ that changes in magnitude as given in Fig. 30-35. The vertical axis scale is set by $B_v = 0.50$ T, and the horizontal axis scale is set by $t_v = 6.00$ s. The loop’s plane is perpendicular to $\mathbf{B}$. What emf is induced in the loop during time intervals (a) 0 to 2.0 s, (b) 2.0 s to 4.0 s, and (c) 4.0 s to 6.0 s?

![Figure 30-36](image)

Figure 30-36 Problem 5.

5 In Fig. 30-36, a wire forms a closed circular loop, of radius $R = 2.0$ m and resistance 4.0 $\Omega$. The circle is centered on a long straight wire; at time $t = 0$, the current in the long straight wire is $5.0$ A rightward. Thereafter, the current changes according to $i = 5.0$ A $- (2.0$ A/s$^2)t^2$. (The straight wire is insulated; so there is no electrical contact between it and the wire of the loop.) What is the magnitude of the current induced in the loop at times $t > 0$?

![Figure 30-37](image)

Figure 30-37 Problem 6.

6 Figure 30-37a shows a circuit consisting of an ideal battery with emf $\varepsilon = 6.00$ $\mu$V, a resistance $R$, and a small wire loop of area 5.0 cm$^2$. For the time interval $t = 10$ s to $t = 20$ s, an external magnetic field is set up throughout the loop. The field is uniform, its direction is into the page in Fig. 30-37a, and the field magnitude is given by $B = at$, where $B$ is in teslas, $a$ is a constant, and $t$ is in seconds. Figure 30-37b gives the current $i$ in the circuit before, during, and after the external field is set up. The vertical axis scale is set by $i_s = 2.0$ mA. Find the constant $a$ in the equation for the field magnitude.
In Fig. 30-38, the magnetic flux through the loop increases according to the relation $\Phi_B = 6.0t^2 + 7.0t$, where $\Phi_B$ is in milliwebers and $t$ is in seconds. (a) What is the magnitude of the emf induced in the loop when $t = 2.0s$? (b) Is the direction of the current through $R$ to the right or left?

A uniform magnetic field $B$ is perpendicular to the plane of a circular loop of diameter 10 cm formed from wire of diameter 2.5 mm and resistivity 1.69 $\times$ 10$^{-8}$ $\Omega$-m. At what rate must the magnitude of $B$ change to induce a 10 A current in the loop?

A small loop of area 6.8 mm$^2$ is placed inside a long solenoid that has 854 turns/cm and carries a sinusoidally varying current $i$ of amplitude 1.28 A and angular frequency 212 rad/s. The central axes of the loop and solenoid coincide. What is the amplitude of the emf induced in the loop?

Figure 30-39 shows a closed loop of wire that consists of a pair of equal semicircles, of radius 3.7 cm, lying in mutually perpendicular planes. The loop was formed by folding a flat circular loop along a diameter until the two halves became perpendicular to each other. A uniform magnetic field $B$ of magnitude 76 mT is directed perpendicular to the fold diameter and makes equal angles (of 45°) with the planes of the semicircles. The magnetic field is reduced to zero at a uniform rate during a time interval of 4.5 ms. During this interval, what are the (a) magnitude and (b) direction (clockwise or counterclockwise when viewed along the direction of $B$) of the emf induced in the loop?

A rectangular coil of $N$ turns and of length $a$ and width $b$ is rotated at frequency $f$ in a uniform magnetic field $B$, as indicated in Fig. 30-40. The coil is connected to rotating cylinders, against which metal brushes slide to make contact. (a) Show that the emf induced in the coil is given (as a function of time $t$) by

$$\varepsilon = 2\pi f N a b B \sin(2\pi ft) = \varepsilon_0 \sin(2\pi ft).$$

This is the principle of the commercial alternating-current generator. (b) What value of $Na b$ gives an emf with $\varepsilon_0 = 150$ V when the loop is rotated at 60.0 rev/s in a uniform magnetic field of 0.500 T?

In Fig. 30-41, a wire loop of lengths $L = 40.0$ cm and $W = 25.0$ cm lies in a magnetic field $B$. What are the (a) magnitude $\varepsilon$ and (b) direction (clockwise or counterclockwise—or “none” if $\varepsilon = 0$) of the emf induced in the loop if $B = (4.00 \times 10^{-2}$ T/m)$\hat{k}$? What are (c) $\varepsilon$ and (d) the direction if $B = (6.00 \times 10^{-2}$ T/m)$\hat{j}$? What are (e) $\varepsilon$ and (f) the direction if $B = (8.00 \times 10^{-2}$ T/m)$\hat{i}$? What are (g) $\varepsilon$ and (h) the direction if $B = (3.00 \times 10^{-2}$ T/m)$\hat{x}$? What are (i) $\varepsilon$ and (j) the direction if $B = (5.00 \times 10^{-2}$ T/m)$\hat{y}$?

One hundred turns of (insulated) copper wire are wrapped around a wooden cylindrical core of cross-sectional area 1.20 $\times$ 10$^{-3}$ m$^2$. The two ends of the wire are connected to a resistor. The total resistance in the circuit is 13.0 $\Omega$. If an externally applied uniform longitudinal magnetic field in the core changes from 1.60 T in one direction to 1.60 T in the opposite direction, how much charge flows through a point in the circuit during the change?

In Fig. 30-42a, a uniform magnetic field $B$ increases in magnitude with time $t$ as given by Fig. 30-42b, where the vertical axis scale is set by $B_1 = 9.0$ mT and the horizontal scale is set by $t_1 = 3.0$ s. A circular conducting loop of area 8.0 $\times$ 10$^{-4}$ m$^2$ lies in the field, in the plane of the page. The amount of charge $q$ passing point $P$ on the loop is given in Fig. 30-42c as a function of $t$, with the vertical axis scale set by $q_1 = 6.0$ mC and the horizontal axis scale again set by $t_1 = 3.0$ s. What is the loop’s resistance?

A square wire loop with sides of 30 cm is placed inside a long solenoid with $N$ turns per meter and an inner radius of 15 cm. The outer radius of the solenoid is 20 cm. The central axes of the loop and solenoid coincide. The magnetic field, with half the area of the loop in the field as shown in Fig. 30-43. The loop contains an ideal battery with emf $\varepsilon = 20.0$ V. If the magnitude of the field varies with time according to $B = 0.0420 - 0.870t$, with $B$ in teslas and $t$ in seconds, what are (a) the net emf in the circuit and (b) the direction of the (net) current around the loop?

A square wire loop with sides of 2.00 m sides is perpendicular to a uniform magnetic field, with half the area of the loop in the field as shown in Fig. 30-44. The area of the loop is 8.0 $\times$ 10$^{-2}$ m$^2$. The loop contains an ideal battery with emf $\varepsilon = 20.0$ V. If the magnitude of the field varies with time according to $B = 0.0420 - 0.870t$, with $B$ in teslas and $t$ in seconds, what are (a) the net emf in the circuit and (b) the direction of the (net) current around the loop?
interior is split into three equal areas, with magnetic fields $\vec{B}_1$, $\vec{B}_2$, and $\vec{B}_3$. The fields are uniform within each region and directly out of or into the page as indicated. Figure 30-44b gives the change in the $z$ component of $\vec{B}_3$ of the three fields with time $t$; the vertical axis scale is set by $B_1 = 4.0 \mu T$ and $B_2 = -2.5B_3$, and the horizontal axis scale is set by $t_i = 2.0 s$. What are the (a) magnitude and (b) direction of the current induced in the wire?

17 A small circular loop of area 2.00 cm$^2$ is placed in the plane of, and concentric with, a large circular loop of radius 1.00 m. The current in the large loop is changed at a constant rate from 200 A to -200 A (a change in direction) in a time of 1.00 s, starting at $t = 0$. What is the magnitude of the magnetic field $\vec{B}$ at the center of the small loop due to the current in the large loop at (a) $t = 0$, (b) $t = 0.500 s$, and (c) $t = 1.00 s$? (d) From $t = 0$ to $t = 1.00 s$, is $\vec{B}$ reversed? Because the inner loop is small, assume $\vec{B}$ is uniform over its area. (e) What emf is induced in the small loop at $t = 0.500 s$?

18 In Fig. 30-45, two straight conducting rails form a right angle. A conducting bar in contact with the rails starts at the vertex at time $t = 0$ and moves with a constant velocity of 5.20 m/s along them. A magnetic field is directed out of the page. Calculate (a) the flux through the triangle formed by the rails and bar at $t = 3.00 s$ and (b) the emf around the triangle at that time. (c) If the emf is $\ell = at^2$, where $a$ and $n$ are constants, what is the value of $n$?

19 An electric generator contains a coil of 100 turns of wire, each forming a rectangular loop 50.0 cm by 30.0 cm. The coil is placed entirely in a uniform magnetic field with magnitude $B = 3.50 T$ and with $\vec{B}$ initially perpendicular to the coil’s plane. What is the maximum value of the emf produced when the coil is spun at 1000 rev/min about an axis perpendicular to $\vec{B}$?

20 At a certain place, Earth’s magnetic field has magnitude $B = 0.590$ gauss and is inclined downward at an angle of 70.0° to the horizontal. A flat horizontal circular coil of wire with a radius of 10.0 cm has 1000 turns and a total resistance of 85.0 $\Omega$. It is connected in series to a meter with 140 $\Omega$ resistance. The coil is flipped through a half-revolution about a diameter, so that it is again horizontal. How much charge flows through the meter during the flip?

21 In Fig. 30-46, a stiff wire bent into a semicircle of radius $a = 2.0$ cm is rotated at constant angular speed 40 rev/s in a uniform 20 mT magnetic field. What are the (a) frequency and (b) amplitude of the emf induced in the loop?

22 A rectangular loop (area = 0.15 m$^2$) turns in a uniform magnetic field, $B = 0.20$ T. When the angle between the field and the normal to the plane of the loop is $\pi/2$ rad and increasing at 0.60 rad/s, what emf is induced in the loop?

23 SSM Figure 30-47 shows two parallel loops of wire having a common axis. The smaller loop (radius $r$) is above the larger loop (radius $R$) by a distance $x \gg R$. Consequently, the magnetic field due to the counterclockwise current $i$ in the larger loop is nearly uniform throughout the smaller loop. Suppose that $x$ is increasing at the constant rate $dx/dt = v$. (a) Find an expression for the magnetic flux through the area of the smaller loop as a function of $x$. (Hint: See Eq. 29-27.) In the smaller loop, find (b) an expression for the induced emf and (c) the direction of the induced current.

24 A wire is bent into three circular segments, each of radius $r = 10$ cm, as shown in Fig. 30-48. Each segment is a quadrant of a circle, $ab$ lying in the $xy$ plane, $bc$ lying in the $yz$ plane, and $ca$ lying in the $zx$ plane. (a) If a uniform magnetic field $\vec{B}$ points in the positive $x$ direction, what is the magnitude of the emf developed in the wire when $\vec{B}$ increases at the rate of 3.0 mT/s? (b) What is the direction of the current in segment $bc$?

25 Two long, parallel copper wires of diameter 2.5 mm carry currents of 10 A in opposite directions. (a) Assuming that their central axes are 20 mm apart, calculate the magnetic flux per meter of wire that exists in the space between those axes. (b) What percentage of this flux lies inside the wires? (c) Repeat part (a) for parallel currents.

26 For the wire arrangement in Fig. 30-49, $a = 12.0$ cm and $b = 16.0$ cm. The current in the long straight wire is $i = 4.50t^2 - 10.0t$, where $i$ is in amperes and $t$ is in seconds. (a) Find the emf in the square loop at $t = 3.00 s$. (b) What is the direction of the induced current in the loop?

27 As seen in Fig. 30-50, a square loop of wire has sides of length 2.0 cm. A magnetic field is directed out of the page; its magnitude is given by $B = 4.00t^2 y$, where $B$ is in teslas, $i$ is in seconds, and $y$ is in meters. At $t = 2.5 s$, what are the (a) magnitude and (b) direction of the emf induced in the loop?

28 In Fig. 30-51, a rectangular loop of wire with length $a = 2.2$ cm, width $b = 0.80$ cm, and resistance $R = 0.40$ m$\Omega$ is placed near an infinitely long wire carrying current $i = 4.7$ A. The loop is then moved away from the wire at constant speed $v = 3.2$ mm/s. When the center of the loop is at distance $r = 1.5 b$, what are (a) the magnitude of the magnetic flux through the loop and (b) the current induced in the loop?
Module 30-2  Induction and Energy Transfers

• 29  In Fig. 30-52, a metal rod is forced to move with constant velocity \( \vec{v} \) along two parallel metal rails, connected with a strip of metal at one end. A magnetic field of magnitude \( B = 0.350 \, \text{T} \) points out of the page. (a) If the rails are separated by \( L = 25.0 \, \text{cm} \) and the speed of the rod is \( 55.0 \, \text{m/s} \), what emf is generated? (b) If the rod has a resistance of \( 18.0 \, \Omega \) and the rails and connector have negligible resistance, what is the current in the rod? (c) At what rate is energy being transferred to thermal energy?

• 30  In Fig. 30-53a, a circular loop of wire is concentric with a solenoid and lies in a plane perpendicular to the solenoid’s central axis. The loop has radius 6.00 cm. The solenoid has radius 2.00 cm, consists of 8000 turns/m, and has a current \( i_{\text{c}} \) varying with time \( t \) as given in Fig. 30-53b, where the vertical axis scale is set by \( i_c = 1.00 \, \text{A} \) and the horizontal axis scale is set by \( t_c = 2.0 \, \text{s} \). Figure 30-53c shows, as a function of time, the energy \( E_{\text{th}} \) that is transferred to thermal energy of the loop; the vertical axis scale is set by \( E_{\text{th}} = 100.0 \, \text{nJ} \). What is the loop’s resistance?

• 31  SSM  ILW  If 50.0 cm of copper wire (diameter = 1.00 mm) is formed into a circular loop and placed perpendicular to a uniform magnetic field that is increasing at the constant rate of 10.0 mT/s, what is the emf generated by the loop? (a) If the wire is connected with a strip of metal at a certain point and \( \vec{B} \) is directed out of the page, fills the region in which the rod moves. Assume that \( L = 10 \, \text{cm} \), \( v = 5.0 \, \text{m/s} \), and \( B = 1.2 \, \text{T} \). What are the (a) magnitude and (b) direction (up or down the page) of the emf induced in the rod? What are the (c) size and (d) direction of the current in the conducting loop? Assume that the resistance of the rod is 0.40 \, \Omega \) and that the resistance of the rails and metal strip is negligibly small. (e) At what rate is thermal energy being generated in the rod? (f) What external force on the rod is needed to maintain \( \vec{v} \)? (g) At what rate does this force do work on the rod?

Module 30-3  Induced Electric Fields

• 36  Figure 30-56 shows two circular regions \( R_1 \) and \( R_2 \) with radii \( r_1 = 20.0 \, \text{cm} \) and \( r_2 = 30.0 \, \text{cm} \). In \( R_1 \) there is a uniform magnetic field of magnitude \( B_1 = 50.0 \, \text{mT} \) directed into the page, and in \( R_2 \) there is a uniform magnetic field of magnitude \( B_2 = 75.0 \, \text{mT} \) directed out of the page (ignore fringing). Both fields are decreasing at the rate of 8.50 mT/s. Calculate the (a) magnitude and (b) direction (up or down the page) of the emf induced in the rod. What are the (c) size and (d) direction of the current in the conducting loop? Assume that the resistance of the rod is 0.40 \, \Omega \) and that the resistance of the rails and metal strip is negligibly small. (e) At what rate is thermal energy being generated in the rod? (f) What external force on the rod is needed to maintain \( \vec{v} \)? (g) At what rate does this force do work on the rod?

• 37  SSM  ILW  A long solenoid has a diameter of 12.0 cm. When a current \( i \) exists in its windings, a uniform magnetic field of magnitude \( B = 30.0 \, \text{mT} \) is produced in its interior. By decreasing \( i \), the field is caused to decrease at the rate of 6.50 mT/s. Calculate the magnitude of the induced electric field (a) 2.20 cm and (b) 8.20 cm from the axis of the solenoid.

• 38  A circular region in an \( xy \) plane is penetrated by a uniform magnetic field in the positive direction of the \( z \) axis. The field’s magnitude \( B \) (in teslas) increases with time \( t \) (in seconds) according to \( B = at \), where \( a \) is a constant. The magnitude \( E \) of the electric field set up by that increase in the magnetic field is given by Fig. 30-57 versus radial distance \( r \); the vertical axis scale is set by \( E_v = 300 \, \mu\text{N/C} \), and the horizontal axis scale is set by \( r_v = 4.00 \, \text{cm} \). Find \( a \).

• 39  The magnetic field of a cylindrical magnet that has a pole-face diameter of 3.3 cm can be varied sinusoidally between 29.6 T and 30.0 T at a frequency of 15 Hz. (The current in a wire wrapped around a permanent magnet is varied to give this variation in the net field.) At a radial distance of 1.6 cm, what is the amplitude of the electric field induced by the variation?
Module 30-4 Inductors and Inductance

40 The inductance of a closely packed coil of 400 turns is 8.0 mH. Calculate the magnetic flux through the coil when the current is 5.0 mA.

41 A circular coil has a 10.0 cm radius and consists of 30.0 closely wound turns of wire. An externally produced magnetic field of magnitude 2.60 mT is perpendicular to the coil. (a) If no current is in the coil, what magnetic flux links its turns? (b) When the current in the coil is 3.80 A in a certain direction, the net flux through the coil is found to vanish. What is the inductance of the coil?

42 Figure 30-58 shows a copper strip of width \( W = 16.0 \text{ cm} \) that has been bent to form a shape that consists of a tube of radius \( R = 1.8 \text{ cm} \) plus two parallel flat extensions. Current \( i = 35 \text{ mA} \) is distributed uniformly across the width so that the tube is effectively a one-turn solenoid. Assume that the magnetic field outside the tube is negligible and the field inside the tube is uniform. What are (a) the magnetic field magnitude inside the tube and (b) the inductance of the tube (excluding the flat extensions)?

43 Two identical long wires of radius \( a = 1.53 \text{ mm} \) are parallel and carry identical currents in opposite directions. Their center-to-center separation is \( d = 14.2 \text{ cm} \). Neglect the flux within the wires but consider the flux in the region between the wires. What is the inductance per unit length of the wires?

Module 30-5 Self-Induction

44 A 12 H inductor carries a current of 2.0 A. At what rate must the current be changed to produce a 60 V emf in the inductor?

45 At a given instant the current and self-induced emf in an inductor are directed as indicated in Fig. 30-59. (a) Is the current increasing or decreasing? (b) The induced emf is 17 V, and the rate of change of the current is 25 kA/s; find the inductance.

46 The current \( i \) through a 4.6 H inductor varies with time \( t \) as shown by the graph of Fig. 30-60, where the vertical axis scale is set by \( i_v = 8.0 \text{ A} \) and the horizontal axis scale is set by \( t_v = 6.0 \text{ ms} \). The inductor has a resistance of 12 \( \Omega \). Find the magnitude of the induced emf \( \xi \) during time intervals (a) 0 to 2 ms, (b) 2 ms to 5 ms, and (c) 5 ms to 6 ms. (Ignore the behavior at the ends of the intervals.)

47 Inductors in series. Two inductors \( L_1 \) and \( L_2 \) are connected in series and are separated by a large distance so that the magnetic field of one cannot affect the other. (a) Show that the equivalent inductance is given by

\[
\frac{1}{L_{\text{eq}}} = \frac{1}{L_1} + \frac{1}{L_2}.
\]

(Hint: Review the derivations for resistors in series and capacitors in parallel. Which is similar here?) (b) What is the generalization of (a) for \( N \) inductors in series?

48 Inductors in parallel. Two inductors \( L_1 \) and \( L_2 \) are connected in parallel and separated by a large distance so that the magnetic field of one cannot affect the other. (a) Show that the equivalent inductance is given by

\[
\frac{1}{L_{\text{eq}}} = \frac{1}{L_1} + \frac{1}{L_2}.
\]

(Hint: Review the derivations for resistors in parallel and capacitors in parallel. Which is similar here?) (b) What is the generalization of (a) for \( N \) inductors in parallel?

49 The inductor arrangement of Fig. 30-61, with \( L_1 = 30.0 \text{ mH} \), \( L_2 = 50.0 \text{ mH} \), \( L_3 = 20.0 \text{ mH} \), and \( L_4 = 15.0 \text{ mH} \), is to be connected to a varying current source. What is the equivalent inductance of the arrangement? (First see Problems 47 and 48.)

50 The current in an RL circuit builds up to one-third of its steady-state value in 5.00 s. Find the inductive time constant.

51 The current in an RL circuit drops from 1.0 A to 10 mA in the first second following removal of the battery from the circuit. If \( L \) is 10 H, find the resistance \( R \) in the circuit.

52 The switch in Fig. 30-15 is closed on \( a \) at time \( t = 0 \). What is the ratio \( \xi_i/\xi \) of the inductor’s self-induced emf to the battery’s emf (a) just after \( t = 0 \) and (b) at \( t = 2.00 \tau_L \)? At what multiple of \( \tau_L \) will \( \xi_i/\xi = 0.500 \)?

53 A solenoid having an inductance of 6.30 \( \mu \text{H} \) is connected in series with a 1.20 k\( \Omega \) resistor. (a) If a 14.0 V battery is connected across the pair, how long will it take for the current to reach 80.0% of its final value? (b) What is the current through the resistor at time \( t \)?

54 In Fig. 30-62, \( V = 100 \text{ V} \), \( R_1 = 10.0 \Omega \), \( R_2 = 20.0 \Omega \), \( R_3 = 30.0 \Omega \), and \( L = 2.00 \text{ H} \). Immediately after switch \( S \) is closed, what are (a) \( i_1 \) and (b) \( i_2 \)? (Let currents in the indicated directions have positive values and currents in the opposite directions have negative values.) A long time later, what are (c) \( i_1 \) and (d) \( i_2 \)? The switch is then reopened. Just then, what are (e) \( i_1 \) and (f) \( i_2 \)? A long time later, what are (g) \( i_1 \) and (h) \( i_2 \)?

55 A battery is connected to a series RL circuit at time \( t = 0 \). At what multiple of \( \tau_L \) will the current be 0.100% less than its equilibrium value?

56 In Fig. 30-63, the inductor has 25 turns and the ideal battery has an emf of 16 V. Figure 30-64 gives the magnetic flux \( \Phi \) through each turn versus the current \( i \) through the inductor. The vertical
axis scale is set by Φ = 4.0 × 10^{-4} \text{T} \cdot \text{m}^2, and the horizontal axis scale is set by i = 2.00 \text{A}. If switch S is closed at time t = 0, at what rate \frac{di}{dt} will the current be changing at t = 1.5 \tau_r? 

**57** In Fig. 30-65, R = 15 \text{Ω}, L = 5.0 \text{H}, the ideal battery has ε = 10 \text{V}, and the fuse in the upper branch is an ideal 3.0 \text{A} fuse. It has zero resistance as long as the current through it remains less than 3.0 \text{A}. If the current reaches 3.0 \text{A}, the fuse “blows” and thereafter has infinite resistance. Switch S is closed at time t = 0. (a) When does the fuse blow? (Hint: Equation 30-41 does not apply. Rethink Eq. 30-39.) (b) Sketch a graph of the current i through the inductor as a function of time. Mark the time at which the fuse blows.

**58** Suppose the emf of the battery in the circuit shown in Fig. 30-16 varies with time t so that the current is given by i(t) = 3.0 + 5.0t, where i is in amperes and t is in seconds. Take R = 4.0 \text{Ω} and L = 6.0 \text{H}, and find an expression for the battery emf as a function of t. (Hint: Apply the loop rule.)

**59** In Fig. 30-66, after switch S is closed at time t = 0, the emf of the source is automatically adjusted to maintain a constant current i through S. (a) Find the current through the inductor as a function of time. (b) At what time is the current through the resistor equal to the current through the inductor?

**60** A wooden toroidal core with a square cross section has an inner radius of 10 \text{cm} and an outer radius of 12 \text{cm}. It is wound with one layer of wire (of diameter 1.0 mm and resistance per meter 0.020 \text{Ω/m}). What are (a) the inductance and (b) the inductive time constant of the resulting toroid? Ignore the thickness of the insulation on the wire.

**Module 30-7 Energy Stored in a Magnetic Field**

**61** A coil is connected in series with a 10.0 \text{kΩ} resistor. An ideal 50.0 \text{V} battery is applied across the two devices, and the current reaches a value of 2.00 \text{mA} after 5.00 \text{ms}. (a) Find the inductance of the coil. (b) How much energy is stored in the coil at this same moment?

**62** A coil with an inductance of 2.0 \text{H} and a resistance of 10 \text{Ω} is suddenly connected to an ideal battery with ε = 100 \text{V}. At 0.10 \text{s after the connection is made,} what is the rate at which (a) energy is being stored in the magnetic field, (b) thermal energy is appearing in the resistance, and (c) energy is being delivered by the battery?

**63** At t = 0, a battery is connected to a series arrangement of a resistor and an inductor. If the inductive time constant is 37.0 \text{ms}, at what time is the rate at which energy is dissipated in the resistor equal to the rate at which energy is stored in the inductor’s magnetic field?

**64** At t = 0, a battery is connected to a series arrangement of a resistor and an inductor. At what multiple of the inductive time constant will the energy stored in the inductor’s magnetic field be 0.500 its steady-state value?

**65** For the circuit of Fig. 30-16, assume that ε = 10.0 \text{V}, R = 6.70 \text{Ω}, and L = 5.50 \text{H}. The ideal battery is connected at time t = 0. (a) How much energy is delivered by the battery during the first 2.00 \text{s}? (b) How much of this energy is stored in the magnetic field of the inductor? (c) How much of this energy is dissipated in the resistor?

**Module 30-8 Energy Density of a Magnetic Field**

**66** A circular loop of wire 50 \text{mm} in radius carries a current of 100 \text{A}. Find the (a) magnetic field strength and (b) energy density at the center of the loop.

**67** A solenoid that is 85.0 \text{cm} long has a cross-sectional area of 17.0 \text{cm}^2. There are 950 turns of wire carrying a current of 6.60 \text{A}. (a) Calculate the energy density of the magnetic field inside the solenoid. (b) Find the total energy stored in the magnetic field there (neglect end effects).

**68** A toroidal inductor with an inductance of 90.0 \text{mH} encloses a volume of 0.0200 \text{m}^3. If the average energy density in the toroid is 70.0 \text{J/m}^3, what is the current through the inductor?

**69** What must be the magnitude of a uniform electric field if it is to have the same energy density as that possessed by a 0.50 \text{T} magnetic field?

**70** Figure 30-67a shows, in cross section, two wires that are straight, parallel, and very long. The ratio \frac{i_2}{i_1} of the current carried by wire 1 to that carried by wire 2 is 1/3. Wire 1 is fixed in place. Wire 2 can be moved along the positive side of the x axis so as to change the magnetic energy density \text{uB} set up by the two currents at the origin. Figure 30-67b gives \text{uB} as a function of the position x of wire 2. The curve has an asymptote of \text{uB} = 1.96 \text{J/m}^3 as x \to \infty, and the horizontal axis scale is set by x_f = 60.0 \text{cm}. What is the value of (a) \text{i}_1 and (b) \text{i}_2?

**71** A length of copper wire carries a current of 10 \text{A} uniformly distributed through its cross section. Calculate the energy density of (a) the magnetic field and (b) the electric field at the surface of the wire. The wire diameter is 2.5 \text{mm}, and its resistance per unit length is 3.3 \text{Ω/km}.

**Module 30-9 Mutual Induction**

**72** Coil 1 has \text{L}_1 = 25 \text{mH} and \text{N}_1 = 100 \text{turns}. Coil 2 has \text{L}_2 = 40 \text{mH} and \text{N}_2 = 200 \text{turns}. The coils are fixed in place; their mutual inductance \text{M} is 3.0 \text{mH}. A 6.0 \text{mA} current in coil 1 is changing at the rate of 4.0 \text{A/s}. (a) What magnetic flux \text{Φ}_2 links coil 1, and (b) what self-induced emf appears in that coil? (c) What magnetic flux \text{Φ}_1 links coil 2, and (d) what mutually induced emf appears in that coil?

**73** Two coils are at fixed locations. When coil 1 has no current and the current in coil 2 increases at the rate 15.0 \text{A/s}, the emf in coil 1 is 25.0 \text{mV}. (a) What is their mutual inductance? (b) When coil 2 has no current and coil 1 has a current of 3.60 \text{A}, what is the flux linkage in coil 2?

**74** Two solenoids are part of the spark coil of an automobile. When the current in one solenoid falls from 6.0 \text{A} to zero in 2.5 \text{ms}, an emf of 30 \text{kV} is induced in the other solenoid. What is the mutual inductance \text{M} of the solenoids?
**75 ILW** A rectangular loop of \(N\) closely packed turns is positioned near a long straight wire as shown in Fig. 30-68. What is the mutual inductance \(M\) for the loop–wire combination if \(N = 100\), \(a = 1.0\,\text{cm}\), \(b = 8.0\,\text{cm}\), and \(l = 30\,\text{cm}\)?

**76** A coil C of \(N\) turns is placed around a long solenoid S of radius \(R\) and \(n\) turns per unit length, as in Fig. 30-69. (a) Show that the mutual inductance for the coil–solenoid combination is given by \(M = \mu_0 \pi R^2 n N\). (b) Explain why \(M\) does not depend on the shape, size, or possible lack of close packing of the coil.

**77 SSM** Two coils connected as shown in Fig. 30-70 separately have inductances \(L_1\) and \(L_2\). Their mutual inductance is \(M\). (a) Show that this combination can be replaced by a single coil of equivalent inductance given by

\[ L_{eq} = L_1 + L_2 + 2M. \]

(b) How could the coils in Fig. 30-70 be reconnected to yield an equivalent inductance of

\[ L_{eq} = L_1 + L_2 - 2M. \]

(This problem is an extension of Problem 47, but the requirement that the coils be far apart has been removed.)

---

**Additional Problems**

**78** At time \(t = 0\), a 12.0 V potential difference is suddenly applied to the leads of a coil of inductance 23.0 mH and a certain resistance \(R\). At time \(t = 0.150\,\text{ms}\), the current through the inductor is changing at the rate of 280 A/s. Evaluate \(R\).

**79 SSM** In Fig. 30-71, the battery is ideal and \(\varepsilon = 10\,\text{V}\), \(R_1 = 5.0\,\Omega\), \(R_2 = 10\,\Omega\), and \(L = 5.0\,\text{H}\). Switch S is closed at time \(t = 0\). Just afterwards, what are (a) \(i_1\), (b) \(i_2\), (c) the current \(i_3\) through the switch, (d) the potential difference \(V_2\) across resistor 2, (e) the potential difference \(V_1\) across the inductor, and (f) the rate of change \(di_3/dt\)? A long time later, what are (g) \(i_1\), (h) \(i_2\), (i) \(i_3\), (j) \(V_2\), (k) \(V_1\), and (l) \(di_3/dt\)?

**80** In Fig. 30-63, \(R = 4.0\,\text{k}\Omega\), \(L = 8.0\,\mu\text{H}\), and the ideal battery has \(\varepsilon = 20\,\text{V}\). How long after switch S is closed is the current 2.0 mA?

**81 SSM** Figure 30-72a shows a rectangular conducting loop of resistance \(R = 0.020\,\Omega\), height \(H = 1.5\,\text{cm}\), and length \(D = 2.5\,\text{cm}\) being pulled at constant speed \(v = 40\,\text{cm/s}\) through two regions of uniform magnetic field. Figure 30-72b gives the current \(i\) induced in the loop as a function of the position \(x\) of the right side of the loop. The vertical axis scale is set by \(i_0 = 3.0\,\mu\text{A}\). For example, a current equal to \(i_1\) is induced clockwise as the loop enters region 1. What are the (a) magnitude and (b) direction (into or out of the page) of the magnetic field in region 1? What are the (c) magnitude and (d) direction of the magnetic field in region 2?

**82** A uniform magnetic field \(\vec{B}\) is perpendicular to the plane of a circular wire loop of radius \(r\). The magnitude of the field varies with time according to \(B = B_0 e^{-\alpha t}\), where \(B_0\) and \(\alpha\) are constants. Find an expression for the emf in the loop as a function of time.

**83** Switch S in Fig. 30-63 is closed at time \(t = 0\), initiating the buildup of current in the 15.0 mH inductor and the 20.0 \(\Omega\) resistor. At what time is the emf across the inductor equal to the potential difference across the resistor?

**84** Figure 30-73a shows two concentric circular regions in which uniform magnetic fields can change. Region 1, with radius \(r_1 = 1.0\,\text{cm}\), has an outward magnetic field \(\vec{B}_1\) that is increasing in magnitude. Region 2, with radius \(r_2 = 2.0\,\text{cm}\), has an outward magnetic field \(\vec{B}_2\) that may also be changing. Imagine that a conducting ring of radius \(R\) is centered on the two regions and then the emf \(\varepsilon\) around the ring is determined. Figure 30-73b gives emf \(\varepsilon\) as a function of the square \(R^2\) of the ring’s radius, to the outer edge of region 2. The vertical axis scale is set by \(\varepsilon_0 = 20.0\,\text{nV}\). What are the rates (a) \(dB_1/dt\) and (b) \(dB_2/dt\)? (c) Is the magnitude of \(\vec{B}_2\) increasing, decreasing, or remaining constant?

**85 SSM** Figure 30-74 shows a uniform magnetic field \(\vec{B}\) confined to a cylindrical volume of radius \(R\). The magnitude of \(\vec{B}\) is decreasing at a constant rate of 10 mT/s. In unit-vector notation, what is the initial acceleration of an electron released at (a) point \(a\) (radial distance \(r = 5.0\,\text{cm}\)), (b) point \(b\) (\(r = 0\)), and (c) point \(c\) (\(r = 5.0\,\text{cm}\))?
87 SSM A square wire loop 20 cm on a side, with resistance 20 mΩ, has its plane normal to a uniform magnetic field of magnitude \( B = 2.0 \) T. If you pull two opposite sides of the loop away from each other, the other two sides automatically draw toward each other, reducing the area enclosed by the loop. If the area is reduced to zero in time \( \Delta t = 0.20 \) s, what are (a) the average emf and (b) the average current induced in the loop during \( \Delta t \)?

88 A coil with 150 turns has a magnetic flux of 50.0 nT \cdot m^2 through each turn when the current is 2.00 mA. (a) What is the inductance of the coil? What are the (b) inductance and (c) flux through each turn when the current is increased to 4.00 mA? (d) What is the maximum emf \( \mathcal{E} \) across the coil when the current through it is given by \( i = (3.00 \) mA\) \cos(377t), with \( t \) in seconds?

89 A coil with an inductance of 2.0 H and a resistance of 10 Ω is suddenly connected to an ideal battery with \( \mathcal{E} = 100 \) V. (a) What is the equilibrium current? (b) How much energy is stored in the magnetic field when this current exists in the coil?

90 How long would it take, following the removal of the battery, for the potential difference across the resistor in an RL circuit (with \( L = 2.00 \) H, \( R = 3.00 \) Ω) to decay to 10.0% of its initial value?

91 SSM In the circuit of Fig. 30-76, \( R_1 = 20 \) kΩ, \( R_2 = 20 \) Ω, \( L = 50 \) mH, and the ideal battery has \( \mathcal{E} = 40 \) V. Switch S has been open for a long time when it is closed at time \( t = 0 \). Just after the switch is closed, what are (a) the current \( i_{bat} \) through the battery and (b) the rate \( di_{bat}/dt \)? At \( t = 3.0 \) µs, what are (c) \( i_{bat} \) and (d) \( di_{bat}/dt \)? A long time later, what are (e) \( i_{bat} \) and (f) \( di_{bat}/dt \)?

92 The flux linkage through a certain coil of 0.75 Ω resistance would be 26 mWb if there were a current of 5.5 A in it. (a) Calculate the inductance of the coil. (b) If a 6.0 V ideal battery were suddenly connected across the coil, how long would it take for the current to rise from 0 to 2.5 A?

93 In Fig. 30-63, a 12.0 V ideal battery, a 20.0 Ω resistor, and an inductor are connected by a switch at time \( t = 0 \). At what rate is the battery transferring energy to the inductor’s field at \( t = 1.61 \) ms?

94 A long cylindrical solenoid with 100 turns/cm has a radius of 1.6 cm. Assume that the magnetic field it produces is parallel to its axis and is uniform in its interior. (a) What is its inductance per meter of length? (b) If the current changes at the rate of 13 A/s, what emf is induced per meter?

95 In Fig. 30-77, \( R_1 = 8.0 \) Ω, \( R_2 = 10 \) Ω, \( L_1 = 0.30 \) H, \( L_2 = 0.20 \) H, and the ideal battery has \( \mathcal{E} = 6.0 \) V. (a) Just after switch S is closed, at what rate is the current in inductor 1 changing? (b) When the circuit is in the steady state, what is the current in inductor 1?

96 A square loop of wire is held in a uniform 0.24 T magnetic field directed perpendicular to the plane of the loop. The length of each side of the square is decreasing at a constant rate of 5.0 cm/s. What emf is induced in the loop when the length is 12 cm?

97 At time \( t = 0 \), a 45 V potential difference is suddenly applied to the leads of a coil with inductance \( L = 50 \) mH and resistance \( R = 180 \) Ω. At what rate is the current through the coil increasing at \( t = 1.2 \) ms?

98 The inductance of a closely wound coil is such that an emf of 3.00 mV is induced when the current changes at the rate of 5.00 A/s. A steady current of 8.00 A produces a magnetic flux of 40.0 \( \mu \)Wb through each turn. (a) Calculate the inductance of the coil. (b) How many turns does the coil have?

99 The magnetic field in the interstellar space of our galaxy has a magnitude of about \( 10^{-10} \) T. How much energy is stored in this field in a cube 10 light-years on edge? (For scale, note that the nearest star is 4.3 light-years distant and the radius of the galaxy is about \( 8 \times 10^4 \) light-years.)

100 Figure 30-78 shows a wire that has been bent into a circular arc of radius \( r = 24.0 \) cm, centered at \( O \). A straight wire \( OP \) can be rotated about \( O \) and makes sliding contact with the arc at \( P \). Another straight wire \( OQ \) completes the conducting loop. The three wires have cross-sectional area 1.20 mm² and resistivity \( 1.70 \times 10^{-8} \) Ω \cdot m, and the apparatus lies in a uniform magnetic field of magnitude \( B = 0.150 \) T directed out of the figure. Wire \( OP \) begins from rest at angle \( \theta = 0 \) and has constant angular acceleration of 12 rad/s². As functions of \( \theta \) (in rad), find (a) the loop’s resistance and (b) the magnetic flux through the loop. (c) For what \( \theta \) is the induced current maximum and (d) what is that maximum?

101 A toroid has a 5.00 cm square cross section, an inside radius of 15.0 cm, 500 turns of wire, and a current of 0.800 A. What is the magnetic flux through the cross section?
CHAPTER 31
Electromagnetic Oscillations
and Alternating Current

31-1 LC OSCILLATIONS

Learning Objectives
After reading this module, you should be able to . . .

31.01 Sketch an LC oscillator and explain which quantities oscillate and what constitutes one period of the oscillation.
31.02 For an LC oscillator, sketch graphs of the potential difference across the capacitor and the current through the inductor as functions of time, and indicate the period $T$ on each graph.
31.03 Explain the analogy between a block–spring oscillator and an LC oscillator.
31.04 For an LC oscillator, apply the relationships between the angular frequency $\omega$ (and the related frequency $f$ and period $T$) and the values of the inductance and capacitance.
31.05 Starting with the energy of a block–spring system, explain the derivation of the differential equation for charge $q(t)$ in an LC oscillator and then identify the solution for $q(t)$.
31.06 For an LC oscillator, calculate the charge $q$ on the capacitor for any given time and identify the amplitude $Q$ of the charge oscillations.
31.07 Starting from the equation giving the charge $q(t)$ on the capacitor in an LC oscillator, find the current $i(t)$ in the inductor as a function of time.
31.08 For an LC oscillator, calculate the current $i$ in the inductor for any given time and identify the amplitude $I$ of the current oscillations.
31.09 For an LC oscillator, apply the relationship between the charge amplitude $Q$, the current amplitude $I$, and the angular frequency $\omega$.
31.10 From the expressions for the charge $q$ and the current $i$ in an LC oscillator, find the magnetic field energy $U_B(t)$ and the electric field energy $U_E(t)$ and the total energy.
31.11 For an LC oscillator, sketch graphs of the magnetic field energy $U_B(t)$, the electric field energy $U_E(t)$, and the total energy, all as functions of time.
31.12 Calculate the maximum values of the magnetic field energy $U_B$ and the electric field energy $U_E$ and also calculate the total energy.

Key Ideas

- In an oscillating LC circuit, energy is shuttled periodically between the electric field of the capacitor and the magnetic field of the inductor; instantaneous values of the two forms of energy are
  \[ U_E = \frac{q^2}{2C} \quad \text{and} \quad U_B = \frac{L_i^2}{2}, \]
  where $q$ is the instantaneous charge on the capacitor and $i$ is the instantaneous current through the inductor.
- The total energy $U$ remains constant.
- The principle of conservation of energy leads to
  \[ L \frac{d^2q}{dt^2} + \frac{1}{C} q = 0 \quad (LC \text{ oscillations}) \]
  as the differential equation of LC oscillations (with no resistance).

- The solution of this differential equation is
  \[ q = Q \cos(\omega t + \phi) \quad (charge), \]
  in which $Q$ is the charge amplitude (maximum charge on the capacitor) and the angular frequency $\omega$ of the oscillations is
  \[ \omega = \frac{1}{\sqrt{LC}}. \]
- The phase constant $\phi$ is determined by the initial conditions (at $t = 0$) of the system.
- The current $i$ in the system at any time $t$ is
  \[ i = -\omega Q \sin(\omega t + \phi) \quad (current), \]
  in which $\omega Q$ is the current amplitude $I$. 

903
What Is Physics?

We have explored the basic physics of electric and magnetic fields and how energy can be stored in capacitors and inductors. We next turn to the associated applied physics, in which the energy stored in one location can be transferred to another location so that it can be put to use. For example, energy produced at a power plant can show up at your home to run a computer. The total worth of this applied physics is now so high that its estimation is almost impossible. Indeed, modern civilization would be impossible without this applied physics.

In most parts of the world, electrical energy is transferred not as a direct current but as a sinusoidally oscillating current (alternating current, or ac). The challenge to both physicists and engineers is to design ac systems that transfer energy efficiently and to build appliances that make use of that energy. Our first step here is to study the oscillations in a circuit with inductance $L$ and capacitance $C$.

**LC Oscillations, Qualitatively**

Of the three circuit elements, resistance $R$, capacitance $C$, and inductance $L$, we have so far discussed the series combinations $RC$ (in Module 27-4) and $RL$ (in Module 30-6). In these two kinds of circuit we found that the charge, current, and potential difference grow and decay exponentially. The time scale of the growth or decay is given by a *time constant* $\tau$, which is either capacitive or inductive.

We now examine the remaining two-element circuit combination $LC$. You will see that in this case the charge, current, and potential difference do not decay exponentially with time but vary sinusoidally (with period $T$ and angular frequency $\omega$). The resulting oscillations of the capacitor’s electric field and the inductor’s magnetic field are said to be **electromagnetic oscillations**. Such a circuit is said to oscillate.

Parts $a$ through $h$ of Fig. 31-1 show succeeding stages of the oscillations in a simple $LC$ circuit. From Eq. 25-21, the energy stored in the electric field of the...
capacitor at any time is

\[ U_E = \frac{q^2}{2C}, \]  

(31-1)

where \( q \) is the charge on the capacitor at that time. From Eq. 30-49, the energy stored in the magnetic field of the inductor at any time is

\[ U_B = \frac{L i^2}{2}, \]  

(31-2)

where \( i \) is the current through the inductor at that time.

We now adopt the convention of representing *instantaneous values* of the electrical quantities of a sinusoidally oscillating circuit with small letters, such as \( q \), and the *amplitudes* of those quantities with capital letters, such as \( Q \). With this convention in mind, let us assume that initially the charge \( q \) on the capacitor in Fig. 31-1 is at its maximum value \( Q \) and that the current \( i \) through the inductor is zero. This initial state of the circuit is shown in Fig. 31-1a. The bar graphs for energy included there indicate that at this instant, with zero current through the inductor and maximum charge on the capacitor, the energy \( U_B \) of the magnetic field is zero and the energy \( U_E \) of the electric field is a maximum. As the circuit oscillates, energy shifts back and forth from one type of stored energy to the other, but the total amount is conserved.

The capacitor now starts to discharge through the inductor, positive charge carriers moving counterclockwise, as shown in Fig. 31-1b. This means that a current \( i \), given by \( dq/dt \) and pointing down in the inductor, is established. As the capacitor’s charge decreases, the energy stored in the electric field within the capacitor also decreases. This energy is transferred to the magnetic field that appears around the inductor because of the current \( i \) that is building up there. Thus, the electric field decreases and the magnetic field builds up as energy is transferred from the electric field to the magnetic field.

The capacitor eventually loses all its charge (Fig. 31-1c) and thus also loses its electric field and the energy stored in that field. The energy has then been fully transferred to the magnetic field of the inductor. The magnetic field is then at its maximum magnitude, and the current through the inductor is then at its maximum value \( I \).

Although the charge on the capacitor is now zero, the counterclockwise current must continue because the inductor does not allow it to change suddenly to zero. The current continues to transfer positive charge from the top plate to the bottom plate through the circuit (Fig. 31-1d). Energy now flows from the inductor back to the capacitor as the electric field within the capacitor builds up again. The current gradually decreases during this energy transfer. When, eventually, the energy has been transferred completely back to the capacitor (Fig. 31-1e), the current has decreased to zero (momentarily). The situation of Fig. 31-1e is like the initial situation, except that the capacitor is now charged oppositely.

The capacitor then starts to discharge again but now with a clockwise current (Fig. 31-1f). Reasoning as before, we see that the clockwise current builds to a maximum (Fig. 31-1g) and then decreases (Fig. 31-1h), until the circuit eventually returns to its initial situation (Fig. 31-1a). The process then repeats at some frequency \( f \) and thus at an angular frequency \( \omega = 2\pi f \). In the ideal LC circuit with no resistance, there are no energy transfers other than that between the electric field of the capacitor and the magnetic field of the inductor. Because of the conservation of energy, the oscillations continue indefinitely. The oscillations need not begin with the energy all in the electric field; the initial situation could be any other stage of the oscillation.
To determine the charge \( q \) on the capacitor as a function of time, we can put a voltmeter to measure the time-varying potential difference (or voltage) \( v_C \) that exists across the capacitor \( C \). From Eq. 25-1 we can write

\[
v_C = \left( \frac{1}{C} \right) q,
\]

which allows us to find \( q \). To measure the current, we can connect a small resistance \( R \) in series with the capacitor and inductor and measure the time-varying potential difference \( v_R \) across it; \( v_R \) is proportional to \( i \) through the relation

\[
v_R = iR.
\]

We assume here that \( R \) is so small that its effect on the behavior of the circuit is negligible. The variations in time of \( v_C \) and \( v_R \), and thus of \( q \) and \( i \), are shown in Fig. 31-2. All four quantities vary sinusoidally.

In an actual \( LC \) circuit, the oscillations will not continue indefinitely because there is always some resistance present that will drain energy from the electric and magnetic fields and dissipate it as thermal energy (the circuit may become warmer). The oscillations, once started, will die away as Fig. 31-3 suggests. Compare this figure with Fig. 15-17, which shows the decay of mechanical oscillations caused by frictional damping in a block–spring system.

**Checkpoint 1**

A charged capacitor and an inductor are connected in series at time \( t = 0 \). In terms of the period \( T \) of the resulting oscillations, determine how much later the following reach their maximum value: (a) the charge on the capacitor; (b) the voltage across the capacitor, with its original polarity; (c) the energy stored in the electric field; and (d) the current.

**The Electrical–Mechanical Analogy**

Let us look a little closer at the analogy between the oscillating \( LC \) system of Fig. 31-1 and an oscillating block–spring system. Two kinds of energy are involved in the block–spring system. One is potential energy of the compressed or extended spring; the other is kinetic energy of the moving block. These two energies are given by the formulas in the first energy column in Table 31-1.

**Table 31-1 Comparison of the Energy in Two Oscillating Systems**

<table>
<thead>
<tr>
<th>Block–Spring System</th>
<th>LC Oscillator</th>

<tr>
<td>Block</td>
<td>Kinetic, ( \frac{1}{2}mv^2 )</td>
</tr>
<tr>
<td>( v = dx/dt )</td>
<td></td>
</tr>
</tbody>
</table>
The table also shows, in the second energy column, the two kinds of energy involved in LC oscillations. By looking across the table, we can see an analogy between the forms of the two pairs of energies—the mechanical energies of the block–spring system and the electromagnetic energies of the LC oscillator. The equations for $v$ and $i$ at the bottom of the table help us see the details of the analogy. They tell us that $q$ corresponds to $x$ and $i$ corresponds to $v$ (in both equations, the former is differentiated to obtain the latter). These correspondences then suggest that, in the energy expressions, $1/C$ corresponds to $k$ and $L$ corresponds to $m$. Thus,

$q$ corresponds to $x$, $\quad 1/C$ corresponds to $k$,
$i$ corresponds to $v$, and $\quad L$ corresponds to $m$.

These correspondences suggest that in an LC oscillator, the capacitor is mathematically like the spring in a block–spring system and the inductor is like the block.

In Module 15-1 we saw that the angular frequency of oscillation of a (frictionless) block–spring system is

$$\omega = \sqrt{\frac{k}{m}} \quad \text{(block–spring system).} \quad (31-3)$$

The correspondences listed above suggest that to find the angular frequency of oscillation for an ideal (resistanceless) LC circuit, $k$ should be replaced by $1/C$ and $m$ by $L$, yielding

$$\omega = \frac{1}{\sqrt{LC}} \quad \text{(LC circuit).} \quad (31-4)$$

**LC Oscillations, Quantitatively**

Here we want to show explicitly that Eq. 31-4 for the angular frequency of LC oscillations is correct. At the same time, we want to examine even more closely the analogy between LC oscillations and block–spring oscillations. We start by extending somewhat our earlier treatment of the mechanical block–spring oscillator.

**The Block–Spring Oscillator**

We analyzed block–spring oscillations in Chapter 15 in terms of energy transfers and did not—at that early stage—derive the fundamental differential equation that governs those oscillations. We do so now.

We can write, for the total energy $U$ of a block–spring oscillator at any instant,

$$U = U_b + U_s = \frac{1}{2}mv^2 + \frac{1}{2}kx^2, \quad (31-5)$$

where $U_b$ and $U_s$ are, respectively, the kinetic energy of the moving block and the potential energy of the stretched or compressed spring. If there is no friction—which we assume—the total energy $U$ remains constant with time, even though $v$ and $x$ vary. In more formal language, $dU/dt = 0$. This leads to

$$\frac{dU}{dt} = \frac{d}{dt} \left( \frac{1}{2}mv^2 + \frac{1}{2}kx^2 \right) = mv \frac{dv}{dt} + kx \frac{dx}{dt} = 0. \quad (31-6)$$

Substituting $v = dx/dt$ and $dv/dt = d^2x/dt^2$, we find

$$m \frac{d^2x}{dt^2} + kx = 0 \quad \text{(block–spring oscillations).} \quad (31-7)$$

Equation 31-7 is the fundamental differential equation that governs the frictionless block–spring oscillations.

The general solution to Eq. 31-7 is (as we saw in Eq. 15-3)

$$x = X \cos(\omega t + \phi) \quad \text{(displacement),} \quad (31-8)$$
in which \( X \) is the amplitude of the mechanical oscillations (\( x_m \) in Chapter 15), \( \omega \) is the angular frequency of the oscillations, and \( \phi \) is a phase constant.

**The LC Oscillator**

Now let us analyze the oscillations of a resistanceless \( LC \) circuit, proceeding exactly as we just did for the block–spring oscillator. The total energy \( U \) present at any instant in an oscillating \( LC \) circuit is given by

\[
U = U_B + U_E = \frac{L}{2} \frac{d^2q}{dt^2} + \frac{q^2}{2C},
\]

in which \( U_B \) is the energy stored in the magnetic field of the inductor and \( U_E \) is the energy stored in the electric field of the capacitor. Since we have assumed the circuit resistance to be zero, no energy is transferred to thermal energy and \( U \) remains constant with time. In more formal language, \( dU/dt \) must be zero. This leads to

\[
\frac{dU}{dt} = \frac{d}{dt} \left( \frac{L}{2} \frac{d^2q}{dt^2} + \frac{q^2}{2C} \right) = \frac{L}{2} \frac{d}{dt} \frac{d^2q}{dt^2} + \frac{1}{2C} \frac{dq}{dt} \frac{dq}{dt} = 0. \tag{31-10}
\]

However, \( i = dq/dt \) and \( d^2q/dt^2 = d^2q/dt^2 \). With these substitutions, Eq. 31-10 becomes

\[
L \frac{d^2q}{dt^2} + \frac{1}{C} q = 0 \quad (LC \text{ oscillations}). \tag{31-11}
\]

This is the differential equation that describes the oscillations of a resistanceless \( LC \) circuit. Equations 31-11 and 31-7 are exactly of the same mathematical form.

**Charge and Current Oscillations**

Since the differential equations are mathematically identical, their solutions must also be mathematically identical. Because \( q \) corresponds to \( x \), we can write the general solution of Eq. 31-11, by analogy to Eq. 31-8, as

\[
q = Q \cos(\omega t + \phi) \quad \text{(charge)}, \tag{31-12}
\]

where \( Q \) is the amplitude of the charge variations, \( \omega \) is the angular frequency of the electromagnetic oscillations, and \( \phi \) is the phase constant. Taking the first derivative of Eq. 31-12 with respect to time gives us the current:

\[
i = \frac{dq}{dt} = -\omega Q \sin(\omega t + \phi) \quad \text{(current)}. \tag{31-13}
\]

The amplitude \( I \) of this sinusoidally varying current is

\[
I = \omega Q, \tag{31-14}
\]

and so we can rewrite Eq. 31-13 as

\[
i = -I \sin(\omega t + \phi). \tag{31-15}
\]

**Angular Frequencies**

We can test whether Eq. 31-12 is a solution of Eq. 31-11 by substituting Eq. 31-12 and its second derivative with respect to time into Eq. 31-11. The first derivative of Eq. 31-12 is Eq. 31-13. The second derivative is then

\[
\frac{d^2q}{dt^2} = -\omega^2 Q \cos(\omega t + \phi).
\]

Substituting for \( q \) and \( d^2q/dt^2 \) in Eq. 31-11, we obtain

\[
-L\omega^2 Q \cos(\omega t + \phi) + \frac{1}{C} Q \cos(\omega t + \phi) = 0.
\]
Canceling $Q \cos(\omega t + \phi)$ and rearranging lead to
\[ \omega = \frac{1}{\sqrt{LC}}. \]

Thus, Eq. 31-12 is indeed a solution of Eq. 31-11 if $\omega$ has the constant value $1/\sqrt{LC}$. Note that this expression for $\omega$ is exactly that given by Eq. 31-4.

The phase constant $\phi$ in Eq. 31-12 is determined by the conditions that exist at any certain time—say, $t = 0$. If the conditions yield $\phi = 0$ at $t = 0$, Eq. 31-12 requires that $q = Q$ and Eq. 31-13 requires that $i = 0$; these are the initial conditions represented by Fig. 31-1a.

**Electrical and Magnetic Energy Oscillations**

The electrical energy stored in the $LC$ circuit at time $t$ is, from Eqs. 31-1 and 31-12,

\[ U_E = \frac{q^2}{2C} = \frac{Q^2}{2C} \cos^2(\omega t + \phi). \quad (31-16) \]

The magnetic energy is, from Eqs. 31-2 and 31-13,

\[ U_B = \frac{1}{2}LI^2 = \frac{1}{2}L\omega^2Q^2 \sin^2(\omega t + \phi). \]

Substituting for $\omega$ from Eq. 31-4 then gives us

\[ U_B = \frac{Q^2}{2C} \sin^2(\omega t + \phi). \quad (31-17) \]

Figure 31-4 shows plots of $U_E(t)$ and $U_B(t)$ for the case of $\phi = 0$. Note that

1. The maximum values of $U_E$ and $U_B$ are both $Q^2/2C$.
2. At any instant the sum of $U_E$ and $U_B$ is equal to $Q^2/2C$, a constant.
3. When $U_E$ is maximum, $U_B$ is zero, and conversely.

**Checkpoint 2**

A capacitor in an $LC$ oscillator has a maximum potential difference of 17 V and a maximum energy of 160 $\mu$J. When the capacitor has a potential difference of 5 V and an energy of 10 $\mu$J, what are (a) the emf across the inductor and (b) the energy stored in the magnetic field?

**Sample Problem 31.01  LC oscillator: potential change, rate of current change**

A 1.5 $\mu$F capacitor is charged to 57 V by a battery, which is then removed. At time $t = 0$, a 12 mH coil is connected in series with the capacitor to form an $LC$ oscillator (Fig. 31-1).

(a) What is the potential difference $v_L(t)$ across the inductor as a function of time?

**KEY IDEAS**

1. The current and potential differences of the circuit (both the potential difference of the capacitor and the potential difference of the coil) undergo sinusoidal oscillations.
2. We can still apply the loop rule to these oscillating potential differences, just as we did for the nonoscillating circuits of Chapter 27.

**Calculations:** At any time $t$ during the oscillations, the loop rule and Fig. 31-1 give us

\[ v_L(t) = v_C(t); \quad (31-18) \]

that is, the potential difference $v_L$ across the inductor must always be equal to the potential difference $v_C$ across the capacitor, so that the net potential difference around the circuit is zero. Thus, we will find $v_L(t)$ if we can find $v_C(t)$, and we can find $v_C(t)$ from $q(t)$ with Eq. 25-1 ($q = CV$).

Because the potential difference $v_C(t)$ is maximum when the oscillations begin at time $t = 0$, the charge $q$ on the capacitor must also be maximum then. Thus, phase constant $\phi$ must be zero; so Eq. 31-12 gives us

\[ q = Q \cos \omega t. \quad (31-19) \]
(Note that this cosine function does indeed yield maximum $q (= Q)$ when $t = 0$.) To get the potential difference $v_C(t)$, we divide both sides of Eq. 31-19 by $C$ to write

$$\frac{q}{C} = \frac{Q}{C} \cos \omega t,$$

and then use Eq. 25-1 to write

$$v_C = V_C \cos \omega t.$$

(31-20)

Here, $V_C$ is the amplitude of the oscillations in the potential difference $v_C$ across the capacitor.

Next, substituting $v_C = v_L$ from Eq. 31-18, we find

$$v_L = V_C \cos \omega t.$$

(31-21)

We can evaluate the right side of this equation by first noting that the amplitude $V_C$ is equal to the initial (maximum) potential difference of 57 V across the capacitor. Then we find $\omega$ with Eq. 31-4:

$$\omega = \frac{1}{\sqrt{LC}} = \frac{1}{[(0.012 \, \text{H})(1.5 \times 10^{-6} \, \text{F})]^{0.5}}$$

$$= 7454 \, \text{rad/s} \approx 7500 \, \text{rad/s}.$$

Thus, Eq. 31-21 becomes

$$v_L = (57 \, \text{V}) \cos(7500 \, \text{rad/s}t).$$

(Answer)

(b) What is the maximum rate $\left(\frac{di}{dt}\right)_{\text{max}}$ at which the current $i$ changes in the circuit?

**KEY IDEA**

With the charge on the capacitor oscillating as in Eq. 31-12, the current is in the form of Eq. 31-13. Because $\phi = 0$, that equation gives us

$$i = -\omega Q \sin \omega t.$$

**Calculations:** Taking the derivative, we have

$$\frac{di}{dt} = \frac{d}{dt} (-\omega Q \sin \omega t) = -\omega^2 Q \cos \omega t.$$

We can simplify this equation by substituting $CV_C$ for $Q$ (because we know $C$ and $V_C$ but not $Q$) and $1/\sqrt{LC}$ for $\omega$ according to Eq. 31-4. We get

$$\frac{di}{dt} = -\frac{1}{LC} CV_C \cos \omega t = -\frac{V_C}{L} \cos \omega t.$$

This tells us that the current changes at a varying (sinusoidal) rate, with its maximum rate of change being

$$\frac{V_C}{L} = \frac{57 \, \text{V}}{0.012 \, \text{H}} = 4750 \, \text{A/s} \approx 4800 \, \text{A/s}. \quad (\text{Answer})$$

### 31-2 DAMPED OSCILLATIONS IN AN RLC CIRCUIT

**Learning Objectives**

*After reading this module, you should be able to . . .*

31.13 Draw the schematic of a damped RLC circuit and explain why the oscillations are damped.

31.14 Starting with the expressions for the field energies and the rate of energy loss in a damped RLC circuit, write the differential equation for the charge $q$ on the capacitor.

31.15 For a damped RLC circuit, apply the expression for charge $q(t)$.

**Key Ideas**

- Oscillations in an LC circuit are damped when a dissipative element $R$ is also present in the circuit. Then

$$L \frac{d^2 q}{dt^2} + R \frac{dq}{dt} + \frac{1}{C} q = 0 \quad (\text{RLC circuit}).$$

31.16 Identify that in a damped RLC circuit, the charge amplitude and the amplitude of the electric field energy decrease exponentially with time.

31.17 Apply the relationship between the angular frequency $\omega'$ of a given damped RLC oscillator and the angular frequency $\omega$ of the circuit if $R$ is removed.

31.18 For a damped RLC circuit, apply the expression for the electric field energy $U_E$ as a function of time.

- The solution of this differential equation is

$$q = Q e^{-R/2L} \cos(\omega' t + \phi),$$

where

$$\omega' = \sqrt{\omega^2 - (R/2L)^2}.$$

We consider only situations with small $R$ and thus small damping; then $\omega' \approx \omega$. 
Damped Oscillations in an RLC Circuit

A circuit containing resistance, inductance, and capacitance is called an RLC circuit. We shall here discuss only series RLC circuits like that shown in Fig. 31-5. With a resistance $R$ present, the total electromagnetic energy $U$ of the circuit (the sum of the electrical energy and magnetic energy) is no longer constant; instead, it decreases with time as energy is transferred to thermal energy in the resistance. Because of this loss of energy, the oscillations of charge, current, and potential difference continuously decrease in amplitude, and the oscillations are said to be damped, just as with the damped block-spring oscillator of Module 15-5.

To analyze the oscillations of this circuit, we write an equation for the total electromagnetic energy $U$ in the circuit at any instant. Because the resistance does not store electromagnetic energy, we can use Eq. 31-9:

$$U = U_B + U_E = \frac{Li^2}{2} + \frac{q^2}{2C}. \quad (31-22)$$

Now, however, this total energy decreases as energy is transferred to thermal energy. The rate of that transfer is, from Eq. 26-27,

$$\frac{dU}{dt} = -i^2 R, \quad (31-23)$$

where the minus sign indicates that $U$ decreases. By differentiating Eq. 31-22 with respect to time and then substituting the result in Eq. 31-23, we obtain

$$\frac{dU}{dt} = Li \frac{di}{dt} + \frac{q}{C} \frac{dq}{dt} = -i^2 R.$$ 

Substituting $dq/dt$ for $i$ and $d^2q/dt^2$ for $di/dt$, we obtain

$$L \frac{d^2q}{dt^2} + R \frac{dq}{dt} + \frac{1}{C} q = 0 \quad (RLC \text{ circuit}), \quad (31-24)$$

which is the differential equation for damped oscillations in an RLC circuit.

**Charge Decay.** The solution to Eq. 31-24 is

$$q = Q e^{-Rt/2L} \cos(\omega't + \phi), \quad (31-25)$$

in which

$$\omega' = \sqrt{\omega^2 - (R/2L)^2}, \quad (31-26)$$

where $\omega = 1/\sqrt{LC}$, as with an undamped oscillator. Equation 31-25 tells us how the charge on the capacitor oscillates in a damped RLC circuit; that equation is the electromagnetic counterpart of Eq. 15-42, which gives the displacement of a damped block-spring oscillator.

Equation 31-25 describes a sinusoidal oscillation (the cosine function) with an exponentially decaying amplitude $Q e^{-Rt/2L}$ (the factor that multiplies the cosine). The angular frequency $\omega'$ of the damped oscillations is always less than the angular frequency $\omega$ of the undamped oscillations; however, we shall here consider only situations in which $R$ is small enough for us to replace $\omega'$ with $\omega$.

**Energy Decay.** Let us next find an expression for the total electromagnetic energy $U$ of the circuit as a function of time. One way to do so is to monitor the energy of the electric field in the capacitor, which is given by Eq. 31-1 ($U_E = q^2/2C$). By substituting Eq. 31-25 into Eq. 31-1, we obtain

$$U_E = \frac{q^2}{2C} = \frac{[Q e^{-Rt/2L} \cos(\omega't + \phi)]^2}{2C} = \frac{Q^2}{2C} e^{-Rt/L} \cos^2(\omega't + \phi). \quad (31-27)$$

Thus, the energy of the electric field oscillates according to a cosine-squared term, and the amplitude of that oscillation decreases exponentially with time.
Sample Problem 31.02  Damped RLC circuit: charge amplitude

A series RLC circuit has inductance \( L = 12 \, \text{mH} \), capacitance \( C = 1.6 \, \mu\text{F} \), and resistance \( R = 1.5 \, \Omega \) and begins to oscillate at time \( t = 0 \).

(a) At what time \( t \) will the amplitude of the charge oscillations in the circuit be 50% of its initial value? (Note that we do not know that initial value.)

**KEY IDEA**

The amplitude of the charge oscillations decreases exponentially with time \( t \): According to Eq. 31-25, the charge amplitude at any time \( t \) is \( Qe^{-Rt/2L} \), in which \( Q \) is the amplitude at time \( t = 0 \).

**Calculations:** We want the time when the charge amplitude has decreased to 0.50\( Q \)—that is, when
\[
Qe^{-Rt/2L} = 0.50Q.
\]
We can now cancel \( Q \) (which also means that we can answer the question without knowing the initial charge). Taking the natural logarithms of both sides (to eliminate the exponential function), we have
\[
-\frac{Rt}{2L} = \ln 0.50.
\]
Solving for \( t \) and then substituting given data yield
\[
t = -\frac{2L}{R} \ln 0.50 = \frac{(2)(12 \times 10^{-3} \, \text{H})(\ln 0.50)}{1.5 \, \Omega} \approx 0.0111 \, \text{s} \approx 11 \, \text{ms}.
\]
(Answer)

(b) How many oscillations are completed within this time?

**KEY IDEA**

The time for one complete oscillation is the period \( T = \frac{2\pi}{\omega} \), where the angular frequency for LC oscillations is given by Eq. 31-4 (\( \omega = \frac{1}{\sqrt{LC}} \)).

**Calculation:** In the time interval \( \Delta t = 0.0111 \, \text{s} \), the number of complete oscillations is
\[
\frac{\Delta t}{T} = \frac{\Delta t}{2\pi\sqrt{LC}} = \frac{0.0111 \, \text{s}}{2\pi[(12 \times 10^{-3} \, \text{H})(1.6 \times 10^{-6} \, \text{F})]^{1/2}} \approx 13.
\]
(Answer)
Thus, the amplitude decays by 50% in about 13 complete oscillations. This damping is less severe than that shown in Fig. 31-3, where the amplitude decays by a little more than 50% in one oscillation.

### 31-3 FORCED OSCILLATIONS OF THREE SIMPLE CIRCuits

**Learning Objectives**

After reading this module, you should be able to . . .

- **31.19** Distinguish alternating current from direct current.
- **31.20** For an ac generator, write the emf as a function of time, identifying the emf amplitude and driving angular frequency.
- **31.21** For an ac generator, write the current as a function of time, identifying its amplitude and its phase constant with respect to the emf.
- **31.22** Draw a schematic diagram of a (series) RLC circuit that is driven by a generator.
- **31.23** Distinguish driving angular frequency \( \omega_d \) from natural angular frequency \( \omega \).
- **31.24** In a driven (series) RLC circuit, identify the conditions for resonance and the effect of resonance on the current amplitude.
- **31.25** For each of the three basic circuits (purely resistive load, purely capacitive load, and purely inductive load), draw the circuit and sketch graphs and phasor diagrams for voltage \( v(t) \) and current \( i(t) \).
- **31.26** For the three basic circuits, apply equations for voltage \( v(t) \) and current \( i(t) \).
- **31.27** On a phasor diagram for each of the basic circuits, identify angular speed, amplitude, projection on the vertical axis, and rotation angle.
- **31.28** For each basic circuit, identify the phase constant, and interpret it in terms of the relative orientations of the current phasor and voltage phasor and also in terms of leading and lagging.
- **31.29** Apply the mnemonic “ELI positively is the ICE man.”
- **31.30** For each basic circuit, apply the relationships between the voltage amplitude \( V \) and the current amplitude \( I \).
- **31.31** Calculate capacitive reactance \( X_c \) and inductive reactance \( X_L \).
Key Ideas

- A series RLC circuit may be set into forced oscillation at a driving angular frequency \( \omega_d \) by an external alternating emf
  \[ \mathcal{E} = \mathcal{E}_m \sin \omega_d t. \]
- The current driven in the circuit is
  \[ i = I \sin(\omega_d t - \phi), \]
  where \( \phi \) is the phase constant of the current.
- The alternating potential difference across a resistor has amplitude \( V_R = IR \); the current is in phase with the potential difference.
- For a capacitor, \( V_C = IX_C \), in which \( X_C = 1/\omega_c C \) is the capacitive reactance; the current here leads the potential difference by \( 90^\circ \) \( (\phi = -90^\circ = -\pi/2 \text{ rad}) \).
- For an inductor, \( V_L = IX_L \), in which \( X_L = \omega_L L \) is the inductive reactance; the current here lags the potential difference by \( 90^\circ \) \( (\phi = +90^\circ = +\pi/2 \text{ rad}) \).

## Alternating Current

The oscillations in an RLC circuit will not damp out if an external emf device supplies enough energy to make up for the energy dissipated as thermal energy in the resistance \( R \). Circuits in homes, offices, and factories, including countless RLC circuits, receive such energy from local power companies. In most countries the energy is supplied via oscillating emfs and currents—the current is said to be an alternating current, or ac for short. (The nonoscillating current from a battery is said to be a direct current, or dc.) These oscillating emfs and currents vary sinusoidally with time, reversing direction (in North America) 120 times per second and thus having frequency \( f = 60 \text{ Hz} \).

**Electron Oscillations.** At first sight this may seem to be a strange arrangement. We have seen that the drift speed of the conduction electrons in household wiring may typically be \( 4 \times 10^{-5} \text{ m/s} \). If we now reverse their direction every \( 1/60 \text{ s} \), such electrons can move only about \( 3 \times 10^{-7} \text{ m} \) in a half-cycle. At this rate, a typical electron can drift past no more than about 10 atoms in the wiring before it is required to reverse its direction. How, you may wonder, can the electron ever get anywhere?

Although this question may be worrisome, it is a needless concern. The conduction electrons do not have to “get anywhere.” When we say that the current in a wire is one ampere, we mean that charge passes through any plane cutting across that wire at the rate of one coulomb per second. The speed at which the charge carriers cross that plane does not matter directly; one ampere may correspond to many charge carriers moving very slowly or to a few moving very rapidly. Furthermore, the signal to the electrons to reverse directions—which originates in the alternating emf provided by the power company’s generator—is propagated along the conductor at a speed close to that of light. All electrons, no matter where they are located, get their reversal instructions at about the same instant. Finally, we note that for many devices, such as lightbulbs and toasters, the direction of motion is unimportant as long as the electrons do move so as to transfer energy to the device via collisions with atoms in the device.

**Why ac?** The basic advantage of alternating current is this: *As the current alternates, so does the magnetic field that surrounds the conductor.* This makes possible the use of Faraday’s law of induction, which, among other things, means that we can step up (increase) or step down (decrease) the magnitude of an alternating potential difference at will, using a device called a transformer, as we shall discuss later. Moreover, alternating current is more readily adaptable to rotating machinery such as generators and motors than is (nonalternating) direct current.

**Emf and Current.** Figure 31-6 shows a simple model of an ac generator. As the conducting loop is forced to rotate through the external magnetic field \( \vec{B} \), a sinusoidally oscillating emf \( \mathcal{E} \) is induced in the loop:

\[ \mathcal{E} = \mathcal{E}_m \sin \omega_d t. \]  \hfill (31-28)
The *angular frequency* $\omega_d$ of the emf is equal to the angular speed with which the loop rotates in the magnetic field, the *phase* of the emf is $\omega_d t$, and the *amplitude* of the emf is $\mathcal{E}_m$ (where the subscript stands for maximum). When the rotating loop is part of a closed conducting path, this emf produces (drives) a sinusoidal (alternating) current along the path with the same angular frequency $\omega_d$, which then is called the **driving angular frequency**. We can write the current as

$$i = I \sin(\omega_d t - \phi),$$

in which $I$ is the amplitude of the driven current. (The phase $\omega_d t - \phi$ of the current is traditionally written with a minus sign instead of as $\omega_d t + \phi$.) We include a phase constant $\phi$ in Eq. 31-29 because the current $i$ may not be in phase with the emf $\mathcal{E}$. (As you will see, the phase constant depends on the circuit to which the generator is connected.) We can also write the current $i$ in terms of the driving frequency $f_d$ of the emf, by substituting $2\pi f_d$ for $\omega_d$ in Eq. 31-29.

### Forced Oscillations

We have seen that once started, the charge, potential difference, and current in both undamped $LC$ circuits and damped $RLC$ circuits (with small enough $R$) oscillate at angular frequency $\omega = 1/\sqrt{LC}$. Such oscillations are said to be **free oscillations** (free of any external emf), and the angular frequency $\omega$ is said to be the circuit’s **natural angular frequency**.

When the external alternating emf of Eq. 31-28 is connected to an $RLC$ circuit, the oscillations of charge, potential difference, and current are said to be **driven oscillations** or **forced oscillations**. These oscillations always occur at the driving angular frequency $\omega_d$:

> Whatever the natural angular frequency $\omega$ of a circuit may be, forced oscillations of charge, current, and potential difference in the circuit always occur at the driving angular frequency $\omega_d$.

However, as you will see in Module 31-4, the amplitudes of the oscillations very much depend on how close $\omega_d$ is to $\omega$. When the two angular frequencies match—a condition known as **resonance**—the amplitude $I$ of the current in the circuit is maximum.

### Three Simple Circuits

Later in this chapter, we shall connect an external alternating emf device to a series $RLC$ circuit as in Fig. 31-7. We shall then find expressions for the amplitude $I$ and phase constant $\phi$ of the sinusoidally oscillating current in terms of the amplitude $\mathcal{E}_m$ and angular frequency $\omega_d$ of the external emf. First, let’s consider three simpler circuits, each having an external emf and only one other circuit element: $R$, $C$, or $L$. We start with a resistive element (a purely resistive load).

#### A Resistive Load

Figure 31-8 shows a circuit containing a resistance element of value $R$ and an ac generator with the alternating emf of Eq. 31-28. By the loop rule, we have

$$\mathcal{E} - v_R = 0.$$

With Eq. 31-28, this gives us

$$v_R = \mathcal{E}_m \sin \omega_d t.$$

Because the amplitude $V_R$ of the alternating potential difference (or voltage) across the resistance is equal to the amplitude $\mathcal{E}_m$ of the alternating emf, we can
write this as

\[ v_R = V_R \sin \omega_0 t. \]  

From the definition of resistance \( R = \frac{V}{i} \), we can now write the current \( i_R \) in the resistance as

\[ i_R = \frac{v_R}{R} = \frac{V_R}{R} \sin \omega_0 t. \]  

From Eq. 31-29, we can also write this current as

\[ i_R = I_R \sin(\omega_0 t - \phi), \]  

where \( I_R \) is the amplitude of the current \( i_R \) in the resistance. Comparing Eqs. 31-31 and 31-32, we see that for a purely resistive load the phase constant \( \phi = 0^\circ \). We also see that the voltage amplitude and current amplitude are related by

\[ V_R = I_R R \quad \text{(resistor).} \]  

Although we found this relation for the circuit of Fig. 31-8, it applies to any resistance in any ac circuit.

By comparing Eqs. 31-30 and 31-31, we see that the time-varying quantities \( v_R \) and \( i_R \) are both functions of \( \sin \omega_0 t \) with \( \phi = 0^\circ \). Thus, these two quantities are in phase, which means that their corresponding maxima (and minima) occur at the same times. Figure 31-9a, which is a plot of \( v_R(t) \) and \( i_R(t) \), illustrates this fact. Note that \( v_R \) and \( i_R \) do not decay here because the generator supplies energy to the circuit to make up for the energy dissipated in \( R \).

The time-varying quantities \( v_R \) and \( i_R \) can also be represented geometrically by phasors. Recall from Module 16-6 that phasors are vectors that rotate around an origin. Those that represent the voltage across and current in the resistor of Fig. 31-8 are shown in Fig. 31-9b at an arbitrary time \( t \). Such phasors have the following properties:

**Angular speed:** Both phasors rotate counterclockwise about the origin with an angular speed equal to the angular frequency \( \omega_0 \) of \( v_R \) and \( i_R \).

**Length:** The length of each phasor represents the amplitude of the alternating quantity: \( V_R \) for the voltage and \( I_R \) for the current.

**Projection:** The projection of each phasor on the vertical axis represents the value of the alternating quantity at time \( t \): \( v_R \) for the voltage and \( i_R \) for the current.

**Rotation angle:** The rotation angle of each phasor is equal to the phase of the

---

**Figure 31-9** (a) The current \( i_R \) and the potential difference \( v_R \) across the resistor are plotted on the same graph, both versus time \( t \). They are in phase and complete one cycle in one period \( T \). (b) A phasor diagram shows the same thing as (a).
alternating quantity at time \( t \). In Fig. 31-9b, the voltage and current are in phase; so their phasors always have the same phase \( \omega_d t \) and the same rotation angle, and thus they rotate together.

Mentally follow the rotation. Can you see that when the phasors have rotated so that \( \omega_d t = 90^\circ \) (they point vertically upward), they indicate that just then \( v_R = V_R \) and \( i_R = I_R \)? Equations 31-30 and 31-32 give the same results.

**Checkpoint 3**

If we increase the driving frequency in a circuit with a purely resistive load, do (a) amplitude \( V_R \) and (b) amplitude \( I_R \) increase, decrease, or remain the same?

---

**Sample Problem 31.03 Purely resistive load: potential difference and current**

In Fig. 31-8, resistance \( R \) is 200 \( \Omega \) and the sinusoidal alternating emf device operates at amplitude \( \mathcal{E}_m = 36.0 \text{ V} \) and frequency \( f_d = 60.0 \text{ Hz} \).

(a) What is the potential difference \( v_R(t) \) across the resistance as a function of time \( t \), and what is the amplitude \( V_R \) of \( v_R(t) \)?

**KEY IDEA**

In a circuit with a purely resistive load, the potential difference \( v_R(t) \) across the resistance is always equal to the potential difference \( \mathcal{E}(t) \) across the emf device.

**Calculations:** For our situation, \( v_R(t) = \mathcal{E}(t) \) and \( V_R = \mathcal{E}_m \).

Since \( \mathcal{E}_m \) is given, we can write

\[
V_R = \mathcal{E}_m = 36.0 \text{ V}.
\]

(Answer)

To find \( v_R(t) \), we use Eq. 31-28 to write

\[
v_R(t) = \mathcal{E}(t) = \mathcal{E}_m \sin \omega_d t
\]

(31-34)

and then substitute \( \mathcal{E}_m = 36.0 \text{ V} \) and

\[
\omega_d = 2\pi f_d = 2\pi(60 \text{ Hz}) = 120\pi
\]

to obtain

\[
v_R = (36.0 \text{ V} \sin(120\pi t)).
\]

(Answer)

We can leave the argument of the sine in this form for convenience, or we can write it as \((377 \text{ rad/s})t\) or as \((377 \text{ s}^{-1})t\).

(b) What are the current \( i_R(t) \) in the resistance and the amplitude \( I_R \) of \( i_R(t) \)?

**KEY IDEA**

In an ac circuit with a purely resistive load, the alternating current \( i_R(t) \) in the resistance is in phase with the alternating potential difference \( v_R(t) \) across the resistance; that is, the phase constant \( \phi \) for the current is zero.

**Calculations:** Here we can write Eq. 31-29 as

\[
i_R = I_R \sin(\omega_d t - \phi) = I_R \sin \omega_d t.
\]

(31-35)

From Eq. 31-33, the amplitude \( I_R \) is

\[
I_R = \frac{V_R}{R} = \frac{36.0 \text{ V}}{200 \Omega} = 0.180 \text{ A}.
\]

(Answer)

Substituting this and \( \omega_d = 2\pi f_d = 120\pi \) into Eq. 31-35, we have

\[
i_R = (0.180 \text{ A}) \sin(120\pi t).
\]

(Answer)

---

**A Capacitive Load**

Figure 31-10 shows a circuit containing a capacitance and a generator with the alternating emf of Eq. 31-28. Using the loop rule and proceeding as we did when we obtained Eq. 31-30, we find that the potential difference across the capacitor is

\[
v_C = V_C \sin \omega_d t,
\]

(31-36)

where \( V_C \) is the amplitude of the alternating voltage across the capacitor. From the definition of capacitance we can also write

\[
q_C = C V_C = CV_C \sin \omega_d t.
\]

(31-37)

Our concern, however, is with the current rather than the charge. Thus, we differ-
entiate Eq. 31-37 to find
\[ i_C = \frac{dq_C}{dt} = \omega_d CV_C \cos \omega_d t. \quad (31-38) \]

We now modify Eq. 31-38 in two ways. First, for reasons of symmetry of notation, we introduce the quantity \( X_C \), called the \textit{capacitive reactance} of a capacitor, defined as

\[ X_C = \frac{1}{\omega d C} \quad (\text{capacitive reactance}). \quad (31-39) \]

Its value depends not only on the capacitance but also on the driving angular frequency \( \omega_d \). We know from the definition of the capacitive time constant \( \tau = RC \) that the SI unit for \( C \) can be expressed as seconds per ohm. Applying this to Eq. 31-39 shows that the SI unit of \( X_C \) is the ohm, just as for resistance \( R \).

Second, we replace \( \cos \omega_d t \) in Eq. 31-38 with a phase-shifted sine:
\[ \cos \omega_d t = \sin(\omega_d t + 90^\circ). \]

You can verify this identity by shifting a sine curve 90° in the negative direction.

With these two modifications, Eq. 31-38 becomes
\[ i_C = \left( \frac{V_C}{X_C} \right) \sin(\omega_d t + 90^\circ). \quad (31-40) \]

From Eq. 31-29, we can also write the current \( i_C \) in the capacitor of Fig. 31-10 as
\[ i_C = I_C \sin(\omega_d t - \phi), \quad (31-41) \]

where \( I_C \) is the amplitude of \( i_C \). Comparing Eqs. 31-40 and 31-41, we see that for a purely capacitive load the phase constant \( \phi \) for the current is \(-90^\circ\). We also see that the voltage amplitude and current amplitude are related by
\[ V_C = I_C X_C \quad (\text{capacitor}). \quad (31-42) \]

Although we found this relation for the circuit of Fig. 31-10, it applies to any capacitance in any ac circuit.

Comparison of Eqs. 31-36 and 31-40, or inspection of Fig. 31-11a, shows that the quantities \( v_C \) and \( i_C \) are \( 90^\circ, \pi/2 \) rad, or one-quarter cycle, out of phase. Furthermore, we see that \( i_C \) leads \( v_C \), which means that, if you monitored the current \( i_C \) and the potential difference \( v_C \) in the circuit of Fig. 31-10, you would find that \( i_C \) reaches its maximum \textit{before} \( v_C \) does, by one-quarter cycle.
This relation between \( i_C \) and \( v_C \) is illustrated by the phasor diagram of Fig. 31-11b. As the phasors representing these two quantities rotate counterclockwise together, the phasor labeled \( I_C \) does indeed lead that labeled \( V_C \), and by an angle of 90°; that is, the phasor \( I_C \) coincides with the vertical axis one-quarter cycle before the phasor \( V_C \) does. Be sure to convince yourself that the phasor diagram of Fig. 31-11b is consistent with Eqs. 31-36 and 31-40.

**Checkpoint 4**

The figure shows, in (a), a sine curve \( S(t) = \sin(\omega_d t) \) and three other sinusoidal curves \( A(t) \), \( B(t) \), and \( C(t) \), each of the form \( \sin(\omega_d t - \phi) \). (a) Rank the three other curves according to the value of \( \phi \), most positive first and most negative last. (b) Which curve corresponds to which phasor in (b) of the figure? (c) Which curve leads the others?

**Sample Problem 31.04  Purely capacitive load: potential difference and current**

In Fig. 31-10, capacitance \( C \) is 15.0 \( \mu F \) and the sinusoidal alternating emf device operates at amplitude \( \mathcal{E}_m = 36.0 \) V and frequency \( f_d = 60.0 \) Hz.

(a) What are the potential difference \( v_C(t) \) across the capacitance and the amplitude \( V_C \) of \( v_C(t) \)?

**KEY IDEA**

In a circuit with a purely capacitive load, the potential difference \( v_C(t) \) across the capacitance is always equal to the potential difference \( \mathcal{E}(t) \) across the emf device.

**Calculations:** Here we have \( v_C(t) = \mathcal{E}(t) \) and \( V_C = \mathcal{E}_m \). Since \( \mathcal{E}_m \) is given, we have

\[
V_C = \mathcal{E}_m = 36.0 \text{ V}.
\]

(Answer)

To find \( v_C(t) \), we use Eq. 31-28 to write

\[
v_C(t) = \mathcal{E}(t) = \mathcal{E}_m \sin \omega_d t.
\]

(31-43)

Then, substituting \( \mathcal{E}_m = 36.0 \) V and \( \omega_d = 2\pi f_d = 120\pi \) into Eq. 31-43, we have

\[
v_C = (36.0 \text{ V}) \sin(120\pi t).
\]

(Answer)

(b) What are the current \( i_C(t) \) in the circuit as a function of time and the amplitude \( I_C \) of \( i_C(t) \)?

**An Inductive Load**

Figure 31-12 shows a circuit containing an inductance and a generator with the alternating emf of Eq. 31-28. Using the loop rule and proceeding as we did to obtain Eq. 31-30, we find that the potential difference across the inductance is

\[
v_L = V_L \sin \omega_d t,
\]

(31-45)
where $V_L$ is the amplitude of $v_L$. From Eq. 30-35 ($\mathcal{E}_L = -L \, di/dt$), we can write the potential difference across an inductance $L$ in which the current is changing at the rate $di/dt$ as

$$v_L = L \, \frac{di}{dt} \quad (31-46)$$

If we combine Eqs. 31-45 and 31-46, we have

$$\frac{di}{dt} = \frac{V_L}{L} \sin \omega_d t. \quad (31-47)$$

Our concern, however, is with the current, so we integrate:

$$i_L = \int di = \frac{V_L}{L} \int \sin \omega_d t \, dt = -\left( \frac{V_L}{\omega_d L} \right) \cos \omega_d t. \quad (31-48)$$

We now modify this equation in two ways. First, for reasons of symmetry of notation, we introduce the quantity $X_L$, called the inductive reactance of an inductor, which is defined as

$$X_L = \omega_d L \quad (31-49)$$

The value of $X_L$ depends on the driving angular frequency $\omega_d$. The unit of the inductive time constant $\tau_L$ indicates that the SI unit of $X_L$ is the ohm, just as it is for $X_C$ and for $R$.

Second, we replace $-\cos \omega_d t$ in Eq. 31-48 with a phase-shifted sine:

$$-\cos \omega_d t = \sin(\omega_d t - 90^\circ).$$

You can verify this identity by shifting a sine curve 90° in the positive direction.

With these two changes, Eq. 31-48 becomes

$$i_L = \left( \frac{V_L}{X_L} \right) \sin(\omega_d t - 90^\circ). \quad (31-50)$$

From Eq. 31-29, we can also write this current in the inductance as

$$i_L = I_L \sin(\omega_d t - \phi), \quad (31-51)$$

where $I_L$ is the amplitude of the current $i_L$. Comparing Eqs. 31-50 and 31-51, we see that for a purely inductive load the phase constant $\phi$ for the current is $+90^\circ$.

We also see that the voltage amplitude and current amplitude are related by

$$V_L = I_L X_L \quad (31-52)$$

Although we found this relation for the circuit of Fig. 31-12, it applies to any inductance in any ac circuit.

Comparison of Eqs. 31-45 and 31-50, or inspection of Fig. 31-13a, shows that the quantities $i_L$ and $v_L$ are $90^\circ$ out of phase. In this case, however, $i_L$ lags $v_L$; that is, monitoring the current $i_L$ and the potential difference $v_L$ in the circuit of Fig. 31-12 shows that $i_L$ reaches its maximum value after $v_L$ does, by one-quarter cycle. The phasor diagram of Fig. 31-13b also contains this information. As the phasors rotate counterclockwise in the figure, the phasor labeled $I_L$ does indeed lag that labeled $V_L$, and by an angle of $90^\circ$. Be sure to convince yourself that Fig. 31-13b represents Eqs. 31-45 and 31-50.

**Checkpoint 5**

If we increase the driving frequency in a circuit with a purely capacitive load, do (a) amplitude $V_C$ and (b) amplitude $I_C$ increase, decrease, or remain the same? If, instead, the circuit has a purely inductive load, do (c) amplitude $V_L$ and (d) amplitude $I_L$ increase, decrease, or remain the same?
Problem-Solving Tactics

Leading and Lagging in AC Circuits: Table 31-2 summarizes the relations between the current \( i \) and the voltage \( v \) for each of the three kinds of circuit elements we have considered. When an applied alternating voltage produces an alternating current in these elements, the current is always in phase with the voltage across a resistor, always leads the voltage across a capacitor, and always lags the voltage across an inductor.

Many students remember these results with the mnemonic “ELI the ICE man.” ELI contains the letter \( L \) (for inductor), and in it the letter \( I \) (for current) comes after the letter \( E \) (for emf or voltage). Thus, for an inductor, the current lags (comes after) the voltage. Similarly, ICE (which contains a \( C \) for capacitor) means that the current leads (comes before) the voltage. You might also use the modified mnemonic “ELI positively is the ICE man” to remember that the phase constant \( \phi \) is positive for an inductor.

If you have difficulty in remembering whether \( X_C \) is equal to \( \omega C \) (wrong) or \( 1/\omega C \) (right), try remembering that \( C \) is in the “cellar”—that is, in the denominator.

Sample Problem 31.05  Purely inductive load: potential difference and current

In Fig. 31-12, inductance \( L \) is 230 mH and the sinusoidal alternating emf device operates at amplitude \( \mathcal{E}_m = 36.0 \text{ V} \) and frequency \( f_d = 60.0 \text{ Hz} \).

(a) What are the potential difference \( v_L(t) \) across the inductance and the amplitude \( V_L \) of \( v_L(t) \)?

KEY IDEA

In a circuit with a purely inductive load, the potential difference \( v_L(t) \) across the inductance is always equal to the potential difference \( \mathcal{E}(t) \) across the emf device.

Calculations: Here we have \( v_L(t) = \mathcal{E}(t) \) and \( V_L = \mathcal{E}_m \). Since \( \mathcal{E}_m \) is given, we know that

\[
V_L = \mathcal{E}_m = 36.0 \text{ V}.
\]

(Answer)

To find \( v_L(t) \), we use Eq. 31-28 to write

\[
v_L(t) = \mathcal{E}(t) = \mathcal{E}_m \sin \omega_d t.
\]

(31-53)

Then, substituting \( \mathcal{E}_m = 36.0 \text{ V} \) and \( \omega_d = 2\pi f_d = 120\pi \) into Eq. 31-53, we have

\[
v_L = (36.0 \text{ V}) \sin(120\pi t).
\]

(Answer)

(b) What are the current \( i_L(t) \) in the circuit as a function of time and the amplitude \( I_L \) of \( i_L(t) \)?

KEY IDEA

In an ac circuit with a purely inductive load, the alternating current \( i_L(t) \) in the inductance lags the alternating potential difference \( v_L(t) \) by 90°. (In the mnemonic of the problem-solving tactic, this circuit is “positively an ELI circuit,” which tells us that the emf \( E \) leads the current \( I \) and that \( \phi \) is positive.)

Calculations: Because the phase constant \( \phi \) for the current is +90°, or +\( \pi/2 \) rad, we can write Eq. 31-29 as

\[
i_L = I_L \sin(\omega_d t - \phi) = I_L \sin(\omega_d t - \pi/2).
\]

(31-54)

We can find the amplitude \( I_L \) from Eq. 31-52 \( (V_L = I_L X_L) \) if we first find the inductive reactance \( X_L \). From Eq. 31-49 \( (X_L = \omega_d L) \), with \( \omega_d = 2\pi f_d \), we can write

\[
X_L = 2\pi f_d L = (2\pi)(60.0 \text{ Hz})(230 \times 10^{-3} \text{ H})
= 86.7 \Omega.
\]

Then Eq. 31-52 tells us that the current amplitude is

\[
I_L = \frac{V_L}{X_L} = \frac{36.0 \text{ V}}{86.7 \Omega} = 0.415 \text{ A}.
\]

(Answer)

Substituting this and \( \omega_d = 2\pi f_d = 120\pi \) into Eq. 31-54, we have

\[
i_L = (0.415 \text{ A}) \sin(120\pi t - \pi/2).
\]

(Answer)
31-4 THE SERIES RLC CIRCUIT

Learning Objectives

After reading this module, you should be able to . . .

31.32 Draw the schematic diagram of a series RLC circuit.
31.33 Identify the conditions for a mainly inductive circuit, a mainly capacitive circuit, and a resonant circuit.
31.34 For a mainly inductive circuit, a mainly capacitive circuit, and a resonant circuit, sketch graphs for voltage \( v(t) \) and current \( i(t) \) and sketch phasor diagrams, indicating leading, lagging, or resonance.
31.35 Calculate impedance \( Z \).
31.36 Apply the relationship between current amplitude \( I \), impedance \( Z \), and emf amplitude \( E_m \).
31.37 Apply the relationships between phase constant \( \phi \) and voltage amplitudes \( V_L \) and \( V_C \), and also between phase constant \( \phi \), resistance \( R \), and reactances \( X_L \) and \( X_C \).
31.38 Identify the values of the phase constant \( \phi \) corresponding to a mainly inductive circuit, a mainly capacitive circuit, and a resonant circuit.
31.39 For resonance, apply the relationship between the driving angular frequency \( \omega_d \), the natural angular frequency \( \omega \), the inductance \( L \), and the capacitance \( C \).
31.40 Sketch a graph of current amplitude versus the ratio \( \omega_d/\omega \), identifying the portions corresponding to a mainly inductive circuit, a mainly capacitive circuit, and a resonant circuit and indicating what happens to the curve for an increase in the resistance.

Key Ideas

- For a series RLC circuit with an external emf given by
  \[ E = E_m \sin \omega_d t \]
  and current given by
  \[ i = I \sin(\omega_d t - \phi) \]
  the current amplitude is given by
  \[ I = \frac{E_m}{\sqrt{R^2 + (X_L - X_C)^2}} \]
  \[ = \frac{E_m}{\sqrt{R^2 + (\omega_d L - 1/\omega_d C)^2}} \]

- The phase constant is given by
  \[ \tan \phi = \frac{X_L - X_C}{R} \]

- The impedance \( Z \) of the circuit is
  \[ Z = \sqrt{R^2 + (X_L - X_C)^2} \]

- We relate the current amplitude and the impedance with
  \[ I = \frac{E_m}{Z} \]

- The current amplitude \( I \) is maximum \( (I = E_m/R) \) when the driving angular frequency \( \omega_d \) equals the natural angular frequency \( \omega \) of the circuit, a condition known as resonance. Then \( X_C = X_L \), \( \phi = 0 \), and the current is in phase with the emf.

The Series RLC Circuit

We are now ready to apply the alternating emf of Eq. 31-28,
\[ E = E_m \sin \omega_d t \]  \( \text{(applied emf)} \)  \( (31-55) \)
to the full RLC circuit of Fig. 31-7. Because \( R \), \( L \), and \( C \) are in series, the same current
\[ i = I \sin(\omega_d t - \phi) \]  \( (31-56) \)
is driven in all three of them. We wish to find the current amplitude \( I \) and the phase constant \( \phi \) and to investigate how these quantities depend on the driving angular frequency \( \omega_d \). The solution is simplified by the use of phasor diagrams as introduced for the three basic circuits of Module 31-3: capacitive load, inductive load, and resistive load. In particular we shall make use of how the voltage phasor is related to the current phasor for each of those basic circuits. We shall find that series RLC circuits can be separated into three types: mainly capacitive circuits, mainly inductive circuits, and circuits that are in resonance.
The Current Amplitude

We start with Fig. 31-14a, which shows the phasor representing the current of Eq. 31-56 at an arbitrary time $t$. The length of the phasor is the current amplitude $I$, the projection of the phasor on the vertical axis is the current $i$ at time $t$, and the angle of rotation of the phasor is the phase $\omega_d t - \phi$ of the current at time $t$.

Figure 31-14b shows the phasors representing the voltages across $R$, $L$, and $C$ at the same time $t$. Each phasor is oriented relative to the angle of rotation of current phasor $I$ in Fig. 31-14a, based on the information in Table 31-2:

- **Resistor**: Here current and voltage are in phase; so the angle of rotation of voltage phasor $V_R$ is the same as that of phasor $I$.
- **Capacitor**: Here current leads voltage by $90^\circ$; so the angle of rotation of voltage phasor $V_C$ is $90^\circ$ less than that of phasor $I$.
- **Inductor**: Here current lags voltage by $90^\circ$; so the angle of rotation of voltage phasor $V_L$ is $90^\circ$ greater than that of phasor $I$.

Figure 31-14b also shows the instantaneous voltages $v_R$, $v_C$, and $v_L$ across $R$, $C$, and $L$ at time $t$; those voltages are the projections of the corresponding phasors on the vertical axis of the figure.

Figure 31-14c shows the phasor representing the applied emf of Eq. 31-55. The length of the phasor is the emf amplitude $E_m$, the projection of the phasor on the vertical axis is the emf $E$ at time $t$, and the angle of rotation of the phasor is the phase $\omega_d t$ of the emf at time $t$.

From the loop rule we know that at any instant the sum of the voltages $v_R$, $v_C$, and $v_L$ is equal to the applied emf $E$:

$$E = v_R + v_C + v_L.$$  \hspace{1cm} (31-57)

Thus, at time $t$ the projection $\mathcal{E}$ in Fig. 31-14c is equal to the algebraic sum of the projections $v_R$, $v_C$, and $v_L$ in Fig. 31-14b. In fact, as the phasors rotate together, this equality always holds. This means that phasor $\mathcal{E}_m$ in Fig. 31-14c must be equal to the vector sum of the three voltage phasors $V_R$, $V_C$, and $V_L$ in Fig. 31-14b.

That requirement is indicated in Fig. 31-14d, where phasor $\mathcal{E}_m$ is drawn as the sum of phasors $V_R$, $V_L$, and $V_C$. Because phasors $V_L$ and $V_C$ have opposite directions in the figure, we simplify the vector sum by first combining $V_L$ and $V_C$ to form the single phasor $V_L - V_C$. Then we combine that single phasor with $V_R$ to find the net phasor. Again, the net phasor must coincide with phasor $\mathcal{E}_m$, as shown.
Both triangles in Fig. 31-14d are right triangles. Applying the Pythagorean theorem to either one yields
\[ \mathcal{E}_m^2 = V_R^2 + (V_L - V_C)^2. \] (31-58)
From the voltage amplitude information displayed in the rightmost column of Table 31-2, we can rewrite this as
\[ \mathcal{E}_m^2 = (IR)^2 + (IX_L - IX_C)^2, \] (31-59)
and then rearrange it to the form
\[ I = \frac{\mathcal{E}_m}{\sqrt{R^2 + (X_L - X_C)^2}}. \] (31-60)

The denominator in Eq. 31-60 is called the \textbf{impedance} \( Z \) of the circuit for the driving angular frequency \( \omega_d \):
\[ Z = \sqrt{R^2 + (X_L - X_C)^2} \quad \text{(impedance defined).} \] (31-61)

We can then write Eq. 31-60 as
\[ I = \frac{\mathcal{E}_m}{Z}. \] (31-62)

If we substitute for \( X_C \) and \( X_L \) from Eqs. 31-39 and 31-49, we can write Eq. 31-60 more explicitly as
\[ I = \frac{\mathcal{E}_m}{\sqrt{R^2 + (\omega_d L - 1/\omega_d C)^2}} \quad \text{(current amplitude).} \] (31-63)

We have now accomplished half our goal: We have obtained an expression for the current amplitude \( I \) in terms of the sinusoidal driving emf and the circuit elements in a series RLC circuit.

The value of \( I \) depends on the difference between \( \omega_d L \) and \( 1/\omega_d C \) in Eq. 31-63 or, equivalently, the difference between \( X_L \) and \( X_C \) in Eq. 31-60. In either equation, it does not matter which of the two quantities is greater because the difference is always squared.

The current that we have been describing in this module is the \textit{steady-state current} that occurs after the alternating emf has been applied for some time. When the emf is first applied to a circuit, a brief \textit{transient current} occurs. Its duration (before settling down into the steady-state current) is determined by the time constants \( \tau_L = L/R \) and \( \tau_C = RC \) as the inductive and capacitive elements “turn on.” This transient current can, for example, destroy a motor on start-up if it is not properly taken into account in the motor’s circuit design.

\textbf{The Phase Constant}

From the right-hand phasor triangle in Fig. 31-14d and from Table 31-2 we can write
\[ \tan \phi = \frac{V_L - V_C}{V_R} = \frac{IX_L - IX_C}{IR}, \] (31-64)
which gives us
\[ \tan \phi = \frac{X_L - X_C}{R} \quad \text{(phase constant).} \] (31-65)

This is the other half of our goal: an equation for the phase constant \( \phi \) in the sinusoidally driven series RLC circuit of Fig. 31-7. In essence, it gives us three dif-
different results for the phase constant, depending on the relative values of the reactances $X_L$ and $X_C$:

$X_L > X_C$: The circuit is said to be more inductive than capacitive. Equation 31-65 tells us that $\phi$ is positive for such a circuit, which means that phasor $I$ rotates behind phasor $\mathcal{E}_m$ (Fig. 31-15a). A plot of $\mathcal{E}$ and $i$ versus time is like that in Fig. 31-15b. (Figures 31-14c and d were drawn assuming $X_L > X_C$.)

$X_C > X_L$: The circuit is said to be more capacitive than inductive. Equation 31-65 tells us that $\phi$ is negative for such a circuit, which means that phasor $I$ rotates ahead of phasor $\mathcal{E}_m$ (Fig. 31-15c). A plot of $\mathcal{E}$ and $i$ versus time is like that in Fig. 31-15d.

$X_C = X_L$: The circuit is said to be in resonance, a state that is discussed next. Equation 31-65 tells us that $\phi = 0^\circ$ for such a circuit, which means that phasors $\mathcal{E}_m$ and $I$ rotate together (Fig. 31-15e). A plot of $\mathcal{E}$ and $i$ versus time is like that in Fig. 31-15f.

As illustration, let us reconsider two extreme circuits: In the purely inductive circuit of Fig. 31-12, where $X_L$ is nonzero and $X_C = R = 0$, Eq. 31-65 tells us that the circuit’s phase constant is $\phi = +90^\circ$ (the greatest value of $\phi$), consistent with Fig. 31-13b. In the purely capacitive circuit of Fig. 31-10, where $X_C$ is nonzero and $X_L = R = 0$, Eq. 31-65 tells us that the circuit’s phase constant is $\phi = -90^\circ$ (the least value of $\phi$), consistent with Fig. 31-11b.

### Resonance

Equation 31-63 gives the current amplitude $I$ in an $RLC$ circuit as a function of the driving angular frequency $\omega_d$ of the external alternating emf. For a given resistance $R$, that amplitude is a maximum when the quantity $\omega_d L = 1/\omega_d C$ in the

---

**Figure 31-15** Phasor diagrams and graphs of the alternating emf $\mathcal{E}$ and current $i$ for the driven $RLC$ circuit of Fig. 31-7. In the phasor diagram of (a) and the graph of (b), the current $i$ lags the driving emf $\mathcal{E}$ and the current’s phase constant $\phi$ is positive. In (c) and (d), the current $i$ leads the driving emf $\mathcal{E}$ and its phase constant $\phi$ is negative. In (e) and (f), the current $i$ is in phase with the driving emf $\mathcal{E}$ and its phase constant $\phi$ is zero.
denominator is zero—that is, when

$$ \omega_d L = \frac{1}{\omega_d C} $$

or

$$ \omega_d = \frac{1}{\sqrt{LC}} \quad \text{(maximum I).} \quad \text{(31-66)} $$

Because the natural angular frequency $\omega$ of the $RLC$ circuit is also equal to $1/\sqrt{LC}$, the maximum value of $I$ occurs when the driving angular frequency matches the natural angular frequency—that is, at resonance. Thus, in an $RLC$ circuit, resonance and maximum current amplitude $I$ occur when

$$ \omega_d = \omega = \frac{1}{\sqrt{LC}} \quad \text{(resonance).} \quad \text{(31-67)} $$

**Resonance Curves.** Figure 31-16 shows three resonance curves for sinusoidally driven oscillations in three series $RLC$ circuits differing only in $R$. Each curve peaks at its maximum current amplitude $I$ when the ratio $\omega_d/\omega$ is 1.00, but the maximum value of $I$ decreases with increasing $R$. (The maximum $I$ is always $\mathcal{E}_m/R$; to see why, combine Eqs. 31-61 and 31-62.) In addition, the curves increase in width (measured in Fig. 31-16 at half the maximum value of $I$) with increasing $R$. 

![Resonance Curves](image-url)
To make physical sense of Fig. 31-16, consider how the reactances $X_L$ and $X_C$ change as we increase the driving angular frequency $\omega_d$, starting with a value much less than the natural frequency $\omega$. For small $\omega_d$, reactance $X_L (= \omega_d L)$ is small and reactance $X_C (= 1/\omega_d C)$ is large. Thus, the circuit is mainly capacitive and the impedance is dominated by the large $X_C$, which keeps the current low.

As we increase $\omega_d$, reactance $X_C$ remains dominant but decreases while reactance $X_L$ increases. The decrease in $X_C$ decreases the impedance, allowing the current to increase, as we see on the left side of any resonance curve in Fig. 31-16. When the increasing $X_L$ and the decreasing $X_C$ reach equal values, the current is greatest and the circuit is in resonance, with $\omega_d = \omega$.

As we continue to increase $\omega_d$, the increasing reactance $X_L$ becomes progressively more dominant over the decreasing reactance $X_C$. The impedance increases because of $X_L$ and the current decreases, as on the right side of any resonance curve in Fig. 31-16. In summary, then: The low-angular-frequency side of a resonance curve is dominated by the capacitor’s reactance, the high-angular-frequency side is dominated by the inductor’s reactance, and resonance occurs in the middle.

**Checkpoint 6**

Here are the capacitive reactance and inductive reactance, respectively, for three sinusoidally driven series $RLC$ circuits: (1) $50 \, \Omega$, $100 \, \Omega$; (2) $100 \, \Omega$, $50 \, \Omega$; (3) $50 \, \Omega$, $50 \, \Omega$.

(a) For each, does the current lead or lag the applied emf, or are the two in phase?

(b) Which circuit is in resonance?

**Sample Problem 31.06  Current amplitude, impedance, and phase constant**

In Fig. 31-7, let $R = 200 \, \Omega$, $C = 15.0 \, \mu F$, $L = 230 \, mH$, $f_d = 60.0 \, Hz$, and $\xi_m = 36.0 \, V$. (These parameters are those used in the earlier sample problems.)

(a) What is the current amplitude $I$?

**KEY IDEA**

The current amplitude $I$ depends on the amplitude $\xi_m$ of the driving emf and on the impedance $Z$ of the circuit, according to Eq. 31-62 ($I = \xi_m/Z$).

**Calculations:** So, we need to find $Z$, which depends on resistance $R$, capacitive reactance $X_C$, and inductive reactance $X_L$. The circuit’s resistance is the given resistance $R$. Its capacitive reactance is due to the given capacitance and, from an earlier sample problem, $X_C = 177 \, \Omega$. Its inductive reactance is due to the given inductance and, from another sample problem, $X_L = 86.7 \, \Omega$. Thus, the circuit’s impedance is

$$Z = \sqrt{R^2 + (X_L - X_C)^2}$$
$$= \sqrt{(200 \, \Omega)^2 + (86.7 \, \Omega - 177 \, \Omega)^2}$$
$$= 219 \, \Omega.$$

We then find

$$I = \frac{\xi_m}{Z} = \frac{36.0 \, V}{219 \, \Omega} = 0.164 \, A. \quad \text{(Answer)}$$

(b) What is the phase constant $\phi$ of the current in the circuit relative to the driving emf?

**KEY IDEA**

The phase constant depends on the inductive reactance, the capacitive reactance, and the resistance of the circuit, according to Eq. 31-65.

**Calculation:** Solving Eq. 31-65 for $\phi$ leads to

$$\phi = \tan^{-1} \frac{X_L - X_C}{R} = \tan^{-1} \frac{86.7 \, \Omega - 177 \, \Omega}{200 \, \Omega}$$
$$= -24.3^\circ = -0.424 \, \text{rad}. \quad \text{(Answer)}$$

The negative phase constant is consistent with the fact that the load is mainly capacitive; that is, $X_C > X_L$. In the common mnemonic for driven series $RLC$ circuits, this circuit is an *ICE* circuit—the current *leads* the driving emf.
31-5 POWER IN ALTERNATING-CURRENT CIRCUITS

Learning Objectives

After reading this module, you should be able to . . .

31.41 For the current, voltage, and emf in an ac circuit, apply the relationship between the rms values and the amplitudes.

31.42 For an alternating emf connected across a capacitor, an inductor, or a resistor, sketch graphs of the sinusoidal variation of the current and voltage and indicate the peak and rms values.

31.43 Apply the relationship between average power \( P_{\text{avg}} \), rms current \( I_{\text{rms}} \), and resistance \( R \).

31.44 In a driven RLC circuit, calculate the power of each element.

31.45 For a driven RLC circuit in steady state, explain what happens to (a) the value of the average stored energy with time and (b) the energy that the generator puts into the circuit.

31.46 Apply the relationship between the power factor \( \cos \phi \), the resistance \( R \), and the impedance \( Z \).

31.47 Apply the relationship between the average power \( P_{\text{avg}} \), the rms emf \( \overline{E}_{\text{rms}} \), the rms current \( I_{\text{rms}} \), and the power factor \( \cos \phi \).

31.48 Identify what power factor is required in order to maximize the rate at which energy is supplied to a resistive load.

Key Ideas

- In a series RLC circuit, the average power \( P_{\text{avg}} \) of the generator is equal to the production rate of thermal energy in the resistor:

\[
P_{\text{avg}} = I_{\text{rms}}^2 R = \overline{E}_{\text{rms}} I_{\text{rms}} \cos \phi.
\]

- The abbreviation rms stands for root-mean-square; the rms quantities are related to the maximum quantities by:

\[
I_{\text{rms}} = I / \sqrt{2}, \quad V_{\text{rms}} = V / \sqrt{2}, \quad \overline{E}_{\text{rms}} = \overline{E} / \sqrt{2}.
\]

The term \( \cos \phi \) is called the power factor of the circuit.

Power in Alternating-Current Circuits

In the RLC circuit of Fig. 31-7, the source of energy is the alternating-current generator. Some of the energy that it provides is stored in the electric field in the capacitor, some is stored in the magnetic field in the inductor, and some is dissipated as thermal energy in the resistor. In steady-state operation, the average stored energy remains constant. The net transfer of energy is thus from the generator to the resistor, where energy is dissipated.

The instantaneous rate at which energy is dissipated in the resistor can be written, with the help of Eqs. 26-27 and 31-29, as

\[
P = \dot{\mathbf{E}} \cdot \mathbf{R} = [I \sin(\omega t - \phi)]^2 R = I^2 R \sin^2(\omega t - \phi). \tag{31-68}
\]

The average rate at which energy is dissipated in the resistor, however, is the average of Eq. 31-68 over time. Over one complete cycle, the average value of \( \sin \theta \), where \( \theta \) is any variable, is zero (Fig. 31-17a) but the average value of \( \sin^2 \theta \) is \( \frac{1}{2} \) (Fig. 31-17b). (Note in Fig. 31-17b how the shaded areas under the curve but above the horizontal line marked \( +\frac{1}{2} \) exactly fill in the unshaded spaces below that line.) Thus, we can write, from Eq. 31-68,

\[
P_{\text{avg}} = \frac{I^2 R}{2} = \left( \frac{I}{\sqrt{2}} \right)^2 R. \tag{31-69}
\]

The quantity \( I / \sqrt{2} \) is called the root-mean-square, or rms, value of the current \( i \):

\[
I_{\text{rms}} = \frac{I}{\sqrt{2}} \quad (\text{rms current}). \tag{31-70}
\]

We can now rewrite Eq. 31-69 as

\[
P_{\text{avg}} = I_{\text{rms}}^2 R \quad (\text{average power}). \tag{31-71}
\]
Equation 31-71 has the same mathematical form as Eq. 26-27 \((P = \dot{e}R)\); the message here is that if we switch to the rms current, we can compute the average rate of energy dissipation for alternating-current circuits just as for direct-current circuits.

We can also define rms values of voltages and emfs for alternating-current circuits:

\[
V_{\text{rms}} = \frac{V}{\sqrt{2}} \quad \text{and} \quad \mathcal{E}_{\text{rms}} = \frac{\mathcal{E}}{\sqrt{2}} \quad \text{(rms voltage; rms emf)}. \quad (31-72)
\]

Alternating-current instruments, such as ammeters and voltmeters, are usually calibrated to read \(I_{\text{rms}}, V_{\text{rms}}, \) and \(\mathcal{E}_{\text{rms}}.\) Thus, if you plug an alternating-current voltmeter into a household electrical outlet and it reads 120 V, that is an rms voltage. The \textit{maximum} value of the potential difference at the outlet is \(\sqrt{2} \times (120 \text{ V}),\) or 170 V. Generally scientists and engineers report rms values instead of maximum values.

Because the proportionality factor \(1/\sqrt{2}\) in Eqs. 31-70 and 31-72 is the same for all three variables, we can write Eqs. 31-62 and 31-60 as

\[
I_{\text{rms}} = \frac{\mathcal{E}_{\text{rms}}}{Z} = \frac{\mathcal{E}_{\text{rms}}}{\sqrt{R^2 + (X_L - X_C)^2}}, \quad (31-73)
\]

and, indeed, this is the form that we almost always use.

We can use the relationship \(I_{\text{rms}} = \mathcal{E}_{\text{rms}}/Z\) to recast Eq. 31-71 in a useful equivalent way. We write

\[
P_{\text{avg}} = \frac{\mathcal{E}_{\text{rms}}}{Z}I_{\text{rms}}R = \mathcal{E}_{\text{rms}}I_{\text{rms}} \frac{R}{Z}. \quad (31-74)
\]

From Fig. 31-14d, Table 31-2, and Eq. 31-62, however, we see that \(R/Z\) is just the cosine of the phase constant \(\phi:\)

\[
\cos \phi = \frac{V_{\text{rms}}}{\mathcal{E}_{\text{rms}}} = \frac{IR}{IZ} = \frac{R}{Z}. \quad (31-75)
\]

Equation 31-74 then becomes

\[
P_{\text{avg}} = \mathcal{E}_{\text{rms}}I_{\text{rms}} \cos \phi \quad \text{(average power).} \quad (31-76)
\]

in which the term \(\cos \phi\) is called the \textbf{power factor}. Because \(\cos \phi = \cos(-\phi),\) Eq. 31-76 is independent of the sign of the phase constant \(\phi.\)

To maximize the rate at which energy is supplied to a resistive load in an \(RLC\) circuit, we should keep the power factor \(\cos \phi\) as close to unity as possible. This is equivalent to keeping the phase constant \(\phi\) in Eq. 31-29 as close to zero as possible. If, for example, the circuit is highly inductive, it can be made less so by putting more capacitance in the circuit, connected in series. (Recall that putting an additional capacitance into a series of capacitances decreases the equivalent capacitance \(C_{\text{eq}}\) of the series.) Thus, the resulting decrease in \(C_{\text{eq}}\) in the circuit reduces the phase constant and increases the power factor in Eq. 31-76. Power companies place series-connected capacitors throughout their transmission systems to get these results.

\[\square\textbf{Checkpoint 7}\]

(a) If the current in a sinusoidally driven series \(RLC\) circuit leads the emf, would we increase or decrease the capacitance to increase the rate at which energy is supplied to the resistance? (b) Would this change bring the resonant angular frequency of the circuit closer to the angular frequency of the emf or put it farther away?
Sample Problem 31.07  Driven RLC circuit: power factor and average power

A series RLC circuit, driven with \( \mathcal{E}_{\text{rms}} = 120 \text{ V} \) at frequency \( f_d = 60.0 \text{ Hz} \), contains a resistance \( R = 200 \Omega \), an inductance with inductive reactance \( X_L = 80.0 \Omega \), and a capacitance with capacitive reactance \( X_C = 150 \Omega \).

(a) What are the power factor \( \cos \phi \) and phase constant \( \phi \) of the circuit?

**KEY IDEA**

The power factor \( \cos \phi \) can be found from the resistance \( R \) and impedance \( Z \) via Eq. 31-75 (\( \cos \phi = R/Z \)).

**Calculations:** To calculate \( Z \), we use Eq. 31-61:

\[
Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(200 \Omega)^2 + (80.0 \Omega - 150 \Omega)^2} = 211.90 \Omega.
\]

Equation 31-75 then gives us

\[
\cos \phi = \frac{R}{Z} = \frac{200 \Omega}{211.90 \Omega} = 0.9438 = 0.944. \quad \text{(Answer)}
\]

Taking the inverse cosine then yields

\[
\phi = \cos^{-1} 0.944 = \pm 19.3^\circ.
\]

The inverse cosine on a calculator gives only the positive answer here, but both +19.3° and −19.3° have a cosine of 0.944. To determine which sign is correct, we must consider whether the current leads or lags the driving emf. Because \( X_C > X_L \), this circuit is mainly capacitive, with the current leading the emf. Thus, \( \phi \) must be negative:

\[
\phi = -19.3^\circ. \quad \text{(Answer)}
\]

We could, instead, have found \( \phi \) with Eq. 31-65. A calculator would then have given us the answer with the minus sign.

(b) What is the average rate \( P_{\text{avg}} \) at which energy is dissipated in the resistance?

**KEY IDEAS**

There are two ways and two ideas to use: (1) Because the circuit is assumed to be in steady-state operation, the rate at which energy is supplied in the resistance is equal to the rate at which energy is supplied to the circuit, as given by Eq. 31-76 (\( P_{\text{avg}} = \mathcal{E}_{\text{rms}} I_{\text{rms}} \cos \phi \)). (2) The rate at which energy is dissipated in a resistance \( R \) depends on the square of the rms current \( I_{\text{rms}} \) through it, according to Eq. 31-71 (\( P_{\text{avg}} = I_{\text{rms}}^2 R \)).

**First way:** We are given the rms driving emf \( \mathcal{E}_{\text{rms}} \) and we already know \( \cos \phi \) from part (a). The rms current \( I_{\text{rms}} \) is determined by the rms value of the driving emf and the circuit’s impedance \( Z \) (which we know), according to Eq. 31-73:

\[
I_{\text{rms}} = \frac{\mathcal{E}_{\text{rms}}}{Z}.
\]

Substituting this into Eq. 31-76 then leads to

\[
P_{\text{avg}} = \mathcal{E}_{\text{rms}} I_{\text{rms}} \cos \phi = \frac{\mathcal{E}_{\text{rms}}^2}{Z} \cos \phi = \frac{(120 \text{ V})^2}{211.90 \Omega} (0.9438) = 64.1 \text{ W}. \quad \text{(Answer)}
\]

**Second way:** Instead, we can write

\[
P_{\text{avg}} = I_{\text{rms}}^2 R = \frac{\mathcal{E}_{\text{rms}}^2}{Z^2} \cos \phi = \frac{(120 \text{ V})^2}{(211.90 \Omega)^2} (200 \Omega) = 64.1 \text{ W}. \quad \text{(Answer)}
\]

(c) What new capacitance \( C_{\text{new}} \) is needed to maximize \( P_{\text{avg}} \) if the other parameters of the circuit are not changed?

**KEY IDEAS**

(1) The average rate \( P_{\text{avg}} \) at which energy is supplied and dissipated is maximized if the circuit is brought into resonance with the driving emf. (2) Resonance occurs when \( X_C = X_L \).

**Calculations:** From the given data, we have \( X_C > X_L \). Thus, we must decrease \( X_C \) to reach resonance. From Eq. 31-39 (\( X_C = 1/\omega_d C \)), we see that this means we must increase \( C \) to the new value \( C_{\text{new}} \).

Using Eq. 31-39, we can write the resonance condition \( X_C = X_L \) as

\[
\frac{1}{\omega_d C_{\text{new}}} = X_L.
\]

Substituting \( 2\pi f_d \) for \( \omega_d \) (because we are given \( f_d \) and not \( \omega_d \)) and then solving for \( C_{\text{new}} \), we find

\[
C_{\text{new}} = \frac{1}{2\pi f_d X_L} = \frac{1}{(2\pi)(60 \text{ Hz})(80.0 \Omega)} = 3.32 \times 10^{-5} \text{ F} = 33.2 \mu\text{F}. \quad \text{(Answer)}
\]

Following the procedure of part (b), you can show that with \( C_{\text{new}} \), the average power of energy dissipation \( P_{\text{avg}} \) would then be at its maximum value of

\[
P_{\text{avg, max}} = 72.0 \text{ W}.
\]
CHAPTER 31  ELECTROMAGNETIC OSCILLATIONS AND ALTERNATING CURRENT

31-6 TRANSFORMERS

Learning Objectives

After reading this module, you should be able to . . .

31.49 For power transmission lines, identify why the transmission should be at low current and high voltage.
31.50 Identify the role of transformers at the two ends of a transmission line.
31.51 Calculate the energy dissipation in a transmission line.
31.52 Identify a transformer’s primary and secondary.
31.53 Apply the relationship between the voltage and number of turns on the two sides of a transformer.
31.54 Distinguish between a step-down transformer and a step-up transformer.
31.55 Apply the relationship between the current and number of turns on the two sides of a transformer.
31.56 Apply the relationship between the power into and out of an ideal transformer.
31.57 Identify the equivalent resistance as seen from the primary side of a transformer.
31.58 Apply the relationship between the equivalent resistance and the actual resistance.
31.59 Explain the role of a transformer in impedance matching.

Key Ideas

A transformer (assumed to be ideal) is an iron core on which are wound a primary coil of \( N_p \) turns and a secondary coil of \( N_s \) turns. If the primary coil is connected across an alternating-current generator, the primary and secondary voltages are related by

\[
V_s = V_p \frac{N_s}{N_p} \quad \text{(transformation of voltage).}
\]

The currents through the coils are related by

\[
I_s = I_p \frac{N_p}{N_s} \quad \text{(transformation of currents).}
\]

The equivalent resistance of the secondary circuit, as seen by the generator, is

\[
R_{eq} = \left( \frac{N_p}{N_s} \right)^2 R_s,
\]

where \( R \) is the resistive load in the secondary circuit. The ratio \( N_p / N_s \) is called the transformer’s turns ratio.

Transformers

Energy Transmission Requirements

When an ac circuit has only a resistive load, the power factor in Eq. 31-76 is \( \cos 0^\circ = 1 \) and the applied rms emf \( \mathcal{E}_{rms} \) is equal to the rms voltage \( V_{rms} \) across the load. Thus, with an rms current \( I_{rms} \) in the load, energy is supplied and dissipated at the average rate of

\[
P_{avg} = \mathcal{E}I = IV.
\]

(In Eq. 31-77 and the rest of this module, we follow conventional practice and drop the subscripts identifying rms quantities. Engineers and scientists assume that all time-varying currents and voltages are reported as rms values; that is what the meters read.) Equation 31-77 tells us that, to satisfy a given power requirement, we have a range of choices for \( I \) and \( V \) provided only that the product \( IV \) is as required.

In electrical power distribution systems it is desirable for reasons of safety and for efficient equipment design to deal with relatively low voltages at both the generating end (the electrical power plant) and the receiving end (the home or factory). Nobody wants an electric toaster to operate at, say, 10 kV. However, in the transmission of electrical energy from the generating plant to the consumer, we want the lowest practical current (hence the largest practical voltage) to minimize \( I^2R \) losses (often called ohmic losses) in the transmission line.

As an example, consider the 735 kV line used to transmit electrical energy from the La Grande 2 hydroelectric plant in Quebec to Montreal, 1000 km away. Suppose that the current is 500 A and the power factor is close to unity. Then from Eq. 31-77, energy is supplied at the average rate

\[
P_{avg} = \mathcal{E}I = (7.35 \times 10^5 \text{ V})(500 \text{ A}) = 368 \text{ MW}.
\]
The resistance of the transmission line is about 0.220 Ω/km; thus, there is a total resistance of about 220 Ω for the 1000 km stretch. Energy is dissipated due to that resistance at a rate of about

\[ P_{\text{avg}} = I^2R = (500 \text{ A})^2(220 \Omega) = 55.0 \text{ MW}, \]

which is nearly 15% of the supply rate.

Imagine what would happen if we doubled the current and halved the voltage. Energy would be supplied by the plant at the same average rate of 368 MW as previously, but now energy would be dissipated at the rate of about

\[ P_{\text{avg}} = I^2R = (1000 \text{ A})^2(220 \Omega) = 220 \text{ MW}, \]

which is almost 60% of the supply rate. Hence the general energy transmission rule: Transmit at the highest possible voltage and the lowest possible current.

The Ideal Transformer

The transmission rule leads to a fundamental mismatch between the requirement for efficient high-voltage transmission and the need for safe low-voltage generation and consumption. We need a device with which we can raise (for transmission) and lower (for use) the ac voltage in a circuit, keeping the product current \( I \) \times voltage essentially constant. The **transformer** is such a device. It has no moving parts, operates by Faraday’s law of induction, and has no simple direct-current counterpart.

The **ideal transformer** in Fig. 31-18 consists of two coils, with different numbers of turns, wound around an iron core. (The coils are insulated from the core.) In use, the primary winding, of \( N_p \) turns, is connected to an alternating-current generator whose emf \( \varnothing \) at any time \( t \) is given by

\[ \varnothing = \varnothing_m \sin \omega t. \]  

The secondary winding, of \( N_s \) turns, is connected to load resistance \( R \), but its circuit is an open circuit as long as switch \( S \) is open (which we assume for the present). Thus, there can be no current through the secondary coil. We assume further for this ideal transformer that the resistances of the primary and secondary windings are negligible. Well-designed, high-capacity transformers can have energy losses as low as 1%; so our assumptions are reasonable.

For the assumed conditions, the primary winding (or **primary**) is a pure inductance and the primary circuit is like that in Fig. 31-12. Thus, the (very small) primary current, also called the **magnetizing current** \( I_{\text{mag}} \), lags the primary voltage \( V_p \) by 90°; the primary’s power factor \( (= \cos \phi \text{ in Eq. 31-76}) \) is zero; so no power is delivered from the generator to the transformer.

However, the small sinusoidally changing primary current \( I_{\text{mag}} \) produces a sinusoidally changing magnetic flux \( \Phi_p \) in the iron core. The core acts to strengthen the flux and to bring it through the secondary winding (or **secondary**). Because \( \Phi_p \) varies, it induces an emf \( \varnothing_{\text{turn}} \) \( (= d\Phi_p/dt) \) in each turn of the secondary. In fact, this emf per turn \( \varnothing_{\text{turn}} \) is the same in the primary and the secondary. Across the primary, the voltage \( V_p \) is the product of \( \varnothing_{\text{turn}} \) and the number of turns \( N_p \); that is, \( V_p = \varnothing_{\text{turn}}N_p \). Similarly, across the secondary the voltage is \( V_s = \varnothing_{\text{turn}}N_s \). Thus, we can write

\[ \varnothing_{\text{turn}} = \frac{V_p}{N_p} = \frac{V_s}{N_s}, \]

or

\[ V_s = V_p \frac{N_s}{N_p} \] \hspace{1cm} (transformation of voltage) \hspace{1cm} (31-79)

If \( N_s > N_p \), the device is a **step-up transformer** because it steps the primary’s voltage \( V_p \) up to a higher voltage \( V_s \). Similarly, if \( N_s < N_p \), it is a **step-down transformer**.
With switch S open, no energy is transferred from the generator to the rest of the circuit, but when we close S to connect the secondary to the resistive load \( R \), energy is transferred. (In general, the load would also contain inductive and capacitive elements, but here we consider just resistance \( R \).) Here is the process:

1. An alternating current \( I_s \) appears in the secondary circuit, with corresponding energy dissipation rate \( I_s^2R = V_s^2/R \) in the resistive load.
2. This current produces its own alternating magnetic flux in the iron core, and this flux induces an opposing emf in the primary windings.
3. The voltage \( V_p \) of the primary, however, cannot change in response to this opposing emf because it must always be equal to the emf \( \varepsilon \) that is provided by the generator; closing switch S cannot change this fact.
4. To maintain \( V_p \), the generator now produces (in addition to \( I_{mag} \)) an alternating current \( I_p \) in the primary circuit; the magnitude and phase constant of \( I_p \) are just those required for the emf induced by \( I_p \) in the primary to exactly cancel the emf induced there by \( I_s \). Because the phase constant of \( I_p \) is not 90° like that of \( I_{mag} \), this current \( I_p \) can transfer energy to the primary.

**Energy Transfers.** We want to relate \( I_s \) to \( I_p \). However, rather than analyze the foregoing complex process in detail, let us just apply the principle of conservation of energy. The rate at which the generator transfers energy to the primary is equal to \( I_p V_p \). The rate at which the primary then transfers energy to the secondary (via the alternating magnetic field linking the two coils) is \( I_s V_s \). Because we assume that no energy is lost along the way, conservation of energy requires that

\[ I_p V_p = I_s V_s. \]

Substituting for \( V_s \) from Eq. 31-79, we find that

\[ I_s = I_p \frac{N_p}{N_s} \quad \text{(transformation of currents).} \quad (31-80) \]

This equation tells us that the current \( I_s \) in the secondary can differ from the current \( I_p \) in the primary, depending on the turns ratio \( N_p/N_s \).

Current \( I_p \) appears in the primary circuit because of the resistive load \( R \) in the secondary circuit. To find \( I_p \), we substitute \( I_s = V_s/R \) into Eq. 31-80 and then we substitute for \( V_s \) from Eq. 31-79. We find

\[ I_p = \frac{1}{R} \left( \frac{N_s}{N_p} \right)^2 V_p. \quad (31-81) \]

This equation has the form \( I_p = V_p/R_{eq} \) where equivalent resistance \( R_{eq} \) is

\[ R_{eq} = \left( \frac{N_p}{N_s} \right)^2 R. \quad (31-82) \]

This \( R_{eq} \) is the value of the load resistance as “seen” by the generator; the generator produces the current \( I_p \) and voltage \( V_p \) as if the generator were connected to a resistance \( R_{eq} \).

**Impedance Matching**

Equation 31-82 suggests still another function for the transformer. For maximum transfer of energy from an emf device to a resistive load, the resistance of the emf device must equal the resistance of the load. The same relation holds for ac circuits except that the impedance (rather than just the resistance) of the generator must equal that of the load. Often this condition is not met. For example, in a music-playing system, the amplifier has high impedance and the speaker set has low impedance. We can match the impedances of the two devices by coupling them through a transformer that has a suitable turns ratio \( N_p/N_s \).
Sample Problem 31.08  Transformer: turns ratio, average power, rms currents

A transformer on a utility pole operates at $V_p = 8.5$ kV on the primary side and supplies electrical energy to a number of nearby houses at $V_s = 120$ V, both quantities being rms values. Assume an ideal step-down transformer, a purely resistive load, and a power factor of unity.

(a) What is the turns ratio $N_p/N_s$ of the transformer?

**KEY IDEA**

The turns ratio $N_p/N_s$ is related to the (given) rms primary and secondary voltages via Eq. 31-79 ($V_s = V_p N_s/N_p$).

**Calculation:** We can write Eq. 31-79 as

$$\frac{V_p}{V_s} = \frac{N_p}{N_s}.$$  \hspace{1cm} (31-83)

(Note that the right side of this equation is the inverse of the turns ratio.) Inverting both sides of Eq. 31-83 gives us

$$\frac{N_p}{N_s} = \frac{V_p}{V_s} = \frac{8.5 \times 10^3 \text{ V}}{120 \text{ V}} = 70.83 \approx 71.$$  \hspace{1cm} (Answer)

(b) The average rate of energy consumption (or dissipation) in the houses served by the transformer is 78 kW. What are the rms currents in the primary and secondary of the transformer?

**KEY IDEA**

For a purely resistive load, the power factor $\cos \phi$ is unity; thus, the average rate at which energy is supplied and dissipated is given by Eq. 31-77 ($P_{\text{avg}} = \mathcal{E}I = IV$).

**Calculations:** In the primary circuit, with $V_p = 8.5$ kV,

$$I_p = \frac{P_{\text{avg}}}{V_p} = \frac{78 \times 10^3 \text{ W}}{8.5 \times 10^3 \text{ V}} = 9.176 \text{ A} = 9.2 \text{ A}. \hspace{1cm} (\text{Answer})$$

Similarly, in the secondary circuit,

$$I_s = \frac{P_{\text{avg}}}{V_s} = \frac{78 \times 10^3 \text{ W}}{120 \text{ V}} = 650 \text{ A}. \hspace{1cm} (\text{Answer})$$

You can check that $I_s = I_p (N_p/N_s)$ as required by Eq. 31-80.

(c) What is the resistive load $R_s$ in the secondary circuit? What is the corresponding resistive load $R_p$ in the primary circuit?

**One way:** We can use $V = IR$ to relate the resistive load to the rms voltage and current. For the secondary circuit, we find

$$R_s = \frac{V_s}{I_s} = \frac{120 \text{ V}}{650 \text{ A}} = 0.1846 \Omega \approx 0.18 \Omega. \hspace{1cm} (\text{Answer})$$

Similarly, for the primary circuit we find

$$R_p = \frac{V_p}{I_p} = \frac{8.5 \times 10^3 \text{ V}}{9.176 \text{ A}} = 926 \Omega \approx 930 \Omega. \hspace{1cm} (\text{Answer})$$

**Second way:** We use the fact that $R_p$ equals the equivalent resistive load “seen” from the primary side of the transformer, which is a resistance modified by the turns ratio and given by Eq. 31-82 ($R_{eq} = (N_p/N_s)^2 R$). If we substitute $R_p$ for $R_{eq}$ and $R_s$ for $R$, that equation yields

$$R_p = \left(\frac{N_p}{N_s}\right)^2 R_s = (70.83)^2(0.1846 \Omega)$$

$$= 926 \Omega \approx 930 \Omega. \hspace{1cm} (\text{Answer})$$

**Review & Summary**

**LC Energy Transfers**  In an oscillating LC circuit, energy is shuttled periodically between the electric field of the capacitor and the magnetic field of the inductor; instantaneous values of the two forms of energy are

$$U_E = \frac{q^2}{2C} \quad \text{and} \quad U_B = \frac{Li^2}{2}. \hspace{1cm} (31-1, 31-2)$$

where $q$ is the instantaneous charge on the capacitor and $i$ is the instantaneous current through the inductor. The total energy $U (= U_E + U_B)$ remains constant.

**LC Charge and Current Oscillations**  The principle of conservation of energy leads to

$$L \frac{d^2q}{dt^2} + \frac{1}{C} q = 0 \quad (\text{LC oscillations}) \hspace{1cm} (31-11)$$
as the differential equation of LC oscillations (with no resistance). The solution of Eq. 31-11 is
\[ q = Q \cos(\omega t + \phi) \] (charge), \hspace{1cm} (31-12)
in which \( Q \) is the charge amplitude (maximum charge on the capacitor) and the angular frequency \( \omega \) of the oscillations is
\[ \omega = \frac{1}{\sqrt{LC}}. \] \hspace{1cm} (31-4)
The phase constant \( \phi \) in Eq. 31-12 is determined by the initial conditions (at \( t = 0 \)) of the system.

The current \( i \) in the system at any time \( t \) is
\[ i = -\omega Q \sin(\omega t + \phi) \] (current), \hspace{1cm} (31-13)
in which \( \omega Q \) is the current amplitude \( I \).

**Damped Oscillations** Oscillations in an LC circuit are damped when a dissipative element \( R \) is also present in the circuit. Then
\[ L \frac{d^2 q}{dt^2} + R \frac{dq}{dt} + \frac{1}{C} q = 0 \] (RLC circuit). \hspace{1cm} (31-24)
The solution of this differential equation is
\[ q = Q e^{-\alpha t} \cos(\omega' t + \phi), \] \hspace{1cm} (31-25)
where
\[ \omega' = \sqrt{\omega^2 - (R/2L)^2}. \] \hspace{1cm} (31-26)
We consider only situations with small \( R \) and thus small damping; then \( \omega' = \omega \).

**Alternating Currents; Forced Oscillations** A series RLC circuit may be set into forced oscillation at a driving angular frequency \( \omega_d \) by an external alternating emf
\[ \varepsilon = \varepsilon_m \sin \omega_d t. \] \hspace{1cm} (31-28)
The current driven in the circuit is
\[ i = I \sin(\omega_d t - \phi), \] \hspace{1cm} (31-29)
where \( \phi \) is the phase constant of the current.

**Resonance** The current amplitude \( I \) in a series RLC circuit driven by a sinusoidal external emf is a maximum \( (I = \varepsilon_m/R) \) when the driving angular frequency \( \omega_d \) equals the natural angular frequency \( \omega \) of the circuit (that is, at resonance). Then \( X_C = X_L \), \( \phi = 0 \), and the current is in phase with the emf.

**Single Circuit Elements** The alternating potential difference across a resistor has amplitude \( V_R = IR \); the current is in phase with the potential difference.

For a capacitor, \( V_C = IX_C \), in which \( X_C = 1/\omega C \) is the capacitive reactance; the current here leads the potential difference by 90° \( (\phi = -90° = -\pi/2 \text{ rad}) \).

For an inductor, \( V_L = IX_L \), in which \( X_L = \omega L \) is the inductive reactance; the current here lags the potential difference by 90° \( (\phi = +90° = +\pi/2 \text{ rad}) \).

**Series RLC Circuits** For a series RLC circuit with an alternating external emf given by Eq. 31-28 and a resulting alternating current given by Eq. 31-29,
\[ I = \frac{\varepsilon_m}{\sqrt{R^2 + (X_L - X_C)^2}} \] (current amplitude) \hspace{1cm} (31-60, 31-63)
and
\[ \tan \phi = \frac{X_L - X_C}{R} \] (phase constant). \hspace{1cm} (31-65)

Defining the impedance \( Z \) of the circuit as
\[ Z = \sqrt{R^2 + (X_L - X_C)^2} \] (impedance) \hspace{1cm} (31-61)
allows us to write Eq. 31-60 as \( I = \varepsilon_m/Z \).

**Power** In a series RLC circuit, the average power \( P_{avg} \) of the generator is equal to the production rate of thermal energy in the resistor:
\[ P_{avg} = I_{rms}^2 R = \varepsilon_{rms} I_{rms} \cos \phi. \] \hspace{1cm} (31-71, 31-76)
Here rms stands for root-mean-square; the rms quantities are related to the maximum quantities by \( I_{rms} = I/\sqrt{2}, V_{rms} = V/\sqrt{2} \), and \( \varepsilon_{rms} = \varepsilon_m/\sqrt{2} \). The term \( \cos \phi \) is called the power factor of the circuit.

**Transformers** A transformer (assumed to be ideal) is an iron core on which are wound a primary coil of \( N_p \) turns and a secondary coil of \( N_s \) turns. If the primary coil is connected across an alternating-current generator, the primary and secondary voltages are related by
\[ V_s = \frac{N_s}{N_p} V_p \] (transformation of voltage). \hspace{1cm} (31-79)
The currents through the coils are related by
\[ I_s = \frac{N_s}{N_p} I_p \] (transformation of currents), \hspace{1cm} (31-80)
and the equivalent resistance of the secondary circuit, as seen by the generator, is
\[ R_{eq} = \left( \frac{N_s}{N_p} \right)^2 R, \] \hspace{1cm} (31-82)
where \( R \) is the resistive load in the secondary circuit. The ratio \( N_p/N_s \) is called the transformer’s turns ratio.

---

1. Figure 31-19 shows three oscillating LC circuits with identical inductors and capacitors. At a particular time, the charges on the capacitor plates (and thus the electric fields between the plates) are all at their maximum values. Rank the circuits according to the time taken to fully discharge the capacitors during the oscillations, greatest first.
2 Figure 31-20 shows graphs of capacitor voltage $v_C$ for $LC$ circuits 1 and 2, which contain identical capacitances and have the same maximum charge $Q$. Are (a) the inductance $L$ and (b) the maximum current $I$ in circuit 1 greater than, less than, or the same as those in circuit 2?

![Figure 31-20](image)

3 A charged capacitor and an inductor are connected at time $t = 0$. In terms of the period $T$ of the resulting oscillations, what is the first later time at which the following reach a maximum: (a) $U_d$, (b) the magnetic flux through the inductor, (c) $\frac{di}{dt}$, and (d) the emf of the inductor?

4 What values of phase constant $\phi$ in Eq. 31-12 allow situations (a), (c), (e), and (g) of Fig. 31-1 to occur at $t = 0$?

5 Curve $a$ in Fig. 31-21 gives the impedance $Z$ of a driven $RC$ circuit versus the driving angular frequency $\omega_0$. The other two curves are similar but for different values of resistance $R$ and capacitance $C$. Rank the three curves according to the corresponding value of $R$, greatest first.

6 Charges on the capacitors in three oscillating $LC$ circuits vary as: (1) $q = 2 \cos 4t$, (2) $q = 4 \cos t$, (3) $q = 3 \cos 4t$ (with $q$ in coulombs and $t$ in seconds). Rank the circuits according to (a) the current amplitude and (b) the period, greatest first.

7 An alternating emf source with a certain emf amplitude is connected, in turn, to a resistor, a capacitor, and then an inductor. Once connected to one of the devices, the driving frequency $f_d$ is varied and the amplitude $I$ of the resulting current through the device is measured and plotted. Which of the three plots in Fig. 31-22 corresponds to which of the three devices?

![Figure 31-22](image)

8 The values of the phase constant $\phi$ for four sinusoidally driven series $RLC$ circuits are (1) $-15^\circ$, (2) $+35^\circ$, (3) $\pi/3$ rad, and (4) $-\pi/6$ rad. (a) In which is the load primarily capacitive? (b) In which does the current lag the alternating emf?

9 Figure 31-23 shows the current $i$ and driving emf $\varepsilon$ for a series $RLC$ circuit. (a) Is the phase constant positive or negative? (b) To increase the rate at which energy is transferred to the resistive load, should $L$ be increased or decreased? (c) Should, instead, $C$ be increased or decreased?

10 Figure 31-24 shows three situations like those of Fig. 31-15. Is the driving angular frequency greater than, less than, or equal to the resonant angular frequency of the circuit in (a) situation 1, (b) situation 2, and (c) situation 3?

![Figure 31-24](image)

11 Figure 31-25 shows the current $i$ and driving emf $\varepsilon$ for a series $RLC$ circuit. Relative to the emf curve, does the current curve shift leftward or rightward and does the amplitude of that curve increase or decrease if we slightly increase (a) $L$, (b) $C$, and (c) $\omega_0$?

![Figure 31-25](image)

12 Figure 31-25 shows the current $i$ and driving emf $\varepsilon$ for a series $RLC$ circuit. (a) Does the current lead or lag the emf? (b) Is the circuit’s load mainly capacitive or mainly inductive? (c) Is the angular frequency $\omega_0$ of the emf greater than or less than the natural angular frequency $\omega$?

13 Does the phasor diagram of Fig. 31-26 correspond to an alternating emf source connected to a resistor, a capacitor, or an inductor? (b) If the angular speed of the phasors is increased, does the length of the current phasor increase or decrease when the scale of the diagram is maintained?

![Figure 31-26](image)

Module 31-1 LC Oscillations

• 1 An oscillating $LC$ circuit consists of a 75.0 mH inductor and a 3.60 $\mu$F capacitor. If the maximum charge on the capacitor is 2.90 $\mu$C, what are (a) the total energy in the circuit and (b) the maximum current?

• 2 The frequency of oscillation of a certain $LC$ circuit is 200 kHz. At time $t = 0$, plate $A$ of the capacitor has maximum positive charge. At what earliest time $t > 0$ will (a) plate $A$ again have maximum positive charge, (b) the other plate of the capacitor have maximum positive charge, and (c) the inductor have maximum magnetic field?
In a certain oscillating LC circuit, the total energy is converted from electrical energy in the capacitor to magnetic energy in the inductor in 1.50 μs. What are (a) the period of oscillation and (b) the frequency of oscillation? (c) How long after the magnetic energy is a maximum will it be a maximum again?

What is the capacitance of an oscillating LC circuit if the maximum charge on the capacitor is 1.60 μC and the total energy is 140 μJ?

In an oscillating LC circuit, \( L = 1.10 \text{ mH} \) and \( C = 4.00 \mu \text{F} \). The maximum charge on the capacitor is 3.00 μC. Find the maximum current.

A 0.50 kg body oscillates in SHM on a spring that, when extended 2.0 mm from its equilibrium position, has an 8.0 N restoring force. What are (a) the angular frequency of oscillation, (b) the period of oscillation, and (c) the capacitance of an LC circuit with the same period if \( L = 5.0 \text{ H} \)?

The energy in an oscillating LC circuit containing a 1.25 H inductor is 5.70 μJ. The maximum charge on the capacitor is 175 μC. For a mechanical system with the same period, find the (a) mass, (b) spring constant, (c) maximum displacement, and (d) maximum speed.

A single loop consists of inductors \((L_1, L_2, \ldots)\), capacitors \((C_1, C_2, \ldots)\), and resistors \((R_1, R_2, \ldots)\) connected in series as shown, for example, in Fig. 31-27a. Show that regardless of the sequence of these circuit elements in the loop, the behavior of this circuit is identical to that of the simple LC circuit shown in Fig. 31-27b. (Hint: Consider the loop rule and see Problem 47 in Chapter 30.)

In an oscillating LC circuit with \( L = 50 \text{ mH} \) and \( C = 4.0 \mu \text{F} \), the current is initially a maximum. How long will it take before the capacitor is fully charged for the first time?

LC oscillators have been used in circuits connected to loudspeakers to create some of the sounds of electronic music. What inductance must be used with a 6.7 μF capacitor to produce a frequency of 10 kHz, which is near the middle of the audible range of frequencies?

A variable capacitor with a range from 10 to 365 pF is used with a coil to form a variable-frequency LC circuit to tune the input to a radio. (a) What is the ratio of maximum frequency to minimum frequency that can be obtained with such a capacitor? If this circuit is to obtain frequencies from 0.54 MHz to 1.60 MHz, the ratio computed in (a) is too large. By adding a capacitor in parallel to the variable capacitor, this range can be adjusted. To obtain the desired frequency range, (b) what capacitance should be added and (c) what inductance should the coil have?

In an oscillating LC circuit, when 75.0% of the total energy is stored in the inductor’s magnetic field, (a) what multiple of the maximum charge is on the capacitor and (b) what multiple of the maximum current is in the inductor?

In an oscillating LC circuit, \( L = 3.00 \text{ mH} \) and \( C = 2.70 \mu \text{F} \). At \( t = 0 \) the charge on the capacitor is zero and the current is 2.00 A. (a) What is the maximum charge that will appear on the capacitor? (b) At what earliest time \( t > 0 \) is the rate at which energy is stored in the capacitor greatest, and (c) what is that greatest rate?

To construct an oscillating LC system, you can choose from a 10 mH inductor, a 5.0 μF capacitor, and a 2.0 μF capacitor. What are the (a) smallest, (b) second smallest, (c) second largest, and (d) largest oscillation frequency that can be set up by these elements in various combinations?

An oscillating LC circuit consisting of a 1.0 nF capacitor and a 3.0 mH coil has a maximum voltage of 3.0 V. What are (a) the maximum charge on the capacitor, (b) the maximum current through the circuit, and (c) the maximum energy stored in the magnetic field of the coil?

An inductor is connected across a capacitor whose capacitance can be varied by turning a knob. We wish to make the frequency of oscillation of this LC circuit vary linearly with the angle of rotation of the knob, going from \( 2 \times 10^4 \) to \( 4 \times 10^4 \) Hz as the knob turns through 180°. If \( L = 1.0 \text{ mH} \), plot the required capacitance \( C \) as a function of the angle of rotation of the knob.

An oscillating LC circuit has a current amplitude of 7.50 mA, a potential amplitude of 250 mV, and a capacitance of 220 nF. What are (a) the period of oscillation, (b) the maximum energy stored in the capacitor, (c) the maximum energy stored in the inductor, (d) the maximum rate at which the current changes, and (e) the maximum rate at which the inductor gains energy?

Using the loop rule, derive the differential equation for an LC circuit (Eq. 31-11).

In an oscillating LC circuit in which \( C = 4.00 \mu \text{F} \), the maximum potential difference across the capacitor during the oscillations is 1.50 V and the maximum current through the inductor is 50.0 mA. What are (a) the inductance \( L \) and (b) the frequency of the oscillations? (c) How much time is required for the charge on the capacitor to rise from zero to its maximum value?

In an oscillating LC circuit with \( C = 64.0 \mu \text{F} \), the current is given by \( i = (1.60) \sin(2500t + 0.680) \), where \( t \) is in seconds, \( i \) in amperes, and the phase constant in radians. (a) How soon after \( t = 0 \) will the current reach its maximum value? What are (b) the inductance \( L \) and (c) the total energy?

A series circuit containing inductance \( L_1 \) and capacitance \( C_1 \) oscillates at angular frequency \( \omega \). A second series circuit, containing inductance \( L_2 \) and capacitance \( C_2 \), oscillates at the same angular frequency. In terms of \( \omega \), what is the angular frequency of oscillation of a series circuit containing all four of these elements? Neglect resistance. (Hint: Use the formulas for equivalent capacitance and equivalent inductance; see Module 25-3 and Problem 47 in Chapter 30.)
•23 In an oscillating LC circuit, $L = 25.0 \ mH$ and $C = 7.80 \ \mu F$. At time $t = 0$ the current is 9.20 mA, the charge on the capacitor is 3.80 $\mu C$, and the capacitor is charging. What are (a) the total energy in the circuit, (b) the maximum charge on the capacitor, and (c) the maximum current? (d) If the charge on the capacitor is given by $q = Q \cos(\omega t + \phi)$, what is the phase angle $\phi$? (e) Suppose the data are the same, except that the capacitor is discharging at $t = 0$. What then is $\phi$?

Module 31-2 Damped Oscillations in an RLC Circuit

•24 A single-loop circuit consists of a 7.20 $\Omega$ resistor, a 12.0 H inductor, and a 3.20 $\mu F$ capacitor. Initially the capacitor has a charge of 6.20 $\mu C$ and the current is zero. Calculate the charge on the capacitor $N$ complete cycles later for (a) $N = 5$, (b) $N = 10$, and (c) $N = 100$.

•25 ILW What resistance $R$ should be connected in series with an inductance $L = 220 \ mH$ and capacitance $C = 12.0 \ \mu F$ for the maximum charge on the capacitor to decay to 99.0% of its initial value in 50.0 cycles? (Assume $\omega' = \omega$.)

•26 SSM In an oscillating series RLC circuit, find the time required for the maximum energy present in the capacitor during an oscillation to fall to half its initial value. Assume $q = Q$ at $t = 0$.

•27 SSM In an oscillating series RLC circuit, show that $\Delta U/U$, the fraction of the energy lost per cycle of oscillation, is given to a close approximation by $\frac{2\pi R}{\omega L}$. The quantity $\omega L / R$ is often called the $Q$ of the circuit (for quality). A high-$Q$ circuit has low resistance and a low fractional energy loss ($\approx \frac{2\pi}{Q}$) per cycle.

Module 31-3 Forced Oscillations of Three Simple Circuits

•28 A 1.50 $\mu F$ capacitor is connected as in Fig. 31-10 to an ac generator with $\varepsilon_m = 30.0 \ V$. What is the amplitude of the resulting alternating current if the frequency of the emf is (a) 1.00 kHz and (b) 8.00 kHz?

•29 ILW A 50.0 $mH$ inductor is connected as in Fig. 31-12 to an ac generator with $\varepsilon_m = 30.0 \ V$. What is the amplitude of the resulting alternating current if the frequency of the emf is (a) 1.00 kHz and (b) 8.00 kHz?

•30 A 50.0 $\Omega$ resistor is connected as in Fig. 31-8 to an ac generator with $\varepsilon_m = 30.0 \ V$. What is the amplitude of the resulting alternating current if the frequency of the emf is (a) 1.00 kHz and (b) 8.00 kHz?

•31 (a) At what frequency would a 6.0 $mH$ inductor and a 10 $\mu F$ capacitor have the same reactance? (b) What would the reactance be? (c) Show that this frequency would be the natural frequency of an oscillating circuit with the same $L$ and $C$.

•32 SSM An ac generator has emf $\varepsilon = \varepsilon_m \sin \omega_0 t$, with $\varepsilon_m = 25.0 \ V$ and $\omega_0 = 377 \ rads/s$. It is connected to a 12.7 $H$ inductor. (a) What is the maximum value of the current? (b) When the current is a maximum, what is the emf of the generator? (c) When the emf of the generator is $-12.5 \ V$ and increasing in magnitude, what is the current?

•33 SSM An ac generator has emf $\varepsilon = \varepsilon_m \sin (\omega_0 t - \pi/4)$, where $\varepsilon_m = 30.0 \ V$ and $\omega_0 = 350 \ rads/s$. The current produced in a connected circuit is $i(t) = I \sin(\omega_0 t - 3\pi/4)$, where $I = 620 \ mA$. At what time after $t = 0$ does (a) the generator emf first reach a maximum and (b) the current first reach a maximum? (c) The circuit contains a single element other than the generator. Is it a capacitor, an inductor, or a resistor? Justify your answer. (d) What is the value of the capacitance, inductance, or resistance, as the case may be?

•34 SSM An ac generator with emf $\varepsilon = \varepsilon_m \sin \omega_0 t$, where $\varepsilon_m = 25.0 \ V$ and $\omega_0 = 377 \ rads/s$, is connected to a 4.15 $\mu F$ capacitor. (a) What is the maximum value of the current? (b) When the current is a maximum, what is the emf of the generator? (c) When the emf of the generator is $-12.5 \ V$ and increasing in magnitude, what is the current?

Module 31-4 The Series RLC Circuit

•35 ILW A coil of inductance 88 $mH$ and unknown resistance and a 0.94 $\mu F$ capacitor are connected in series with an alternating emf of frequency 930 Hz. If the phase constant between the applied voltage and the current is 75°, what is the resistance of the coil?

•36 An alternating source with a variable frequency, a capacitor with capacitance $C$, and a resistor with resistance $R$ are connected in series. Figure 31-29 gives the impedance $Z$ of the circuit versus the driving angular frequency $\omega_0$; the curve reaches an asymptote of 500 $\Omega$, and the horizontal scale is set by $\omega_0 = 300 \ rads/s$. The figure also gives the reactance $X_C$ for the capacitor versus $\omega_0$. What are (a) $R$ and (b) $C$?

![Figure 31-29 Problem 36.](image)

•37 An electric motor has an effective resistance of 32.0 $\Omega$ and an inductive reactance of 45.0 $\Omega$ when working under load. The voltage amplitude across the alternating source is 420 V. Calculate the current amplitude.

•38 The current amplitude $I$ versus driving angular frequency $\omega_0$ for a driven RLC circuit is given in Fig. 31-30, where the vertical axis scale is set by $I = 4.00 \ A$. The inductance is 200 $\mu H$, and the emf amplitude is 8.0 $V$. What are (a) $Z$, (b) $\phi$, and (c) $P$? (d) Draw a phasor diagram.

•39 Remove the inductor from the circuit in Fig. 31-7 and set $R = 200 \ \Omega$, $C = 15.0 \ \mu F$, $f_0 = 60.0 \ Hz$, and $\varepsilon_m = 36.0 \ V$. What are (a) $Z$, (b) $\phi$, and (c) $P$? (d) Draw a phasor diagram.

•40 An alternating source drives a series RLC circuit with an emf amplitude of 6.00 $V$, at a phase angle of $+30.0^\circ$. When the potential difference across the capacitor reaches its maximum positive value of $+5.00 \ V$, what is the potential difference across the inductor (sign included)?

•41 SSM In Fig. 31-7, set $R = 200 \ \Omega$, $C = 70.0 \ \mu F$, $L = 230 \ mH$, $f_0 = 60.0 \ Hz$, and $\varepsilon_m = 36.0 \ V$. What are (a) $Z$, (b) $\phi$, and (c) $P$? (d) Draw a phasor diagram.

•42 An alternating source with a variable frequency, an inductor
with inductance $L$, and a resistor with resistance $R$ are connected in series. Figure 31-31 gives the impedance $Z$ of the circuit versus the driving angular frequency $\omega_d$, with the horizontal axis scale set by $\omega_d = 1600\, \text{rad/s}$. The figure also gives the reactance $X_L$ for the inductor versus $\omega_d$. What are (a) $R$ and (b) $L$?

**43** Remove the capacitor from the circuit in Fig. 31-7 and set $R = 200\, \Omega$, $L = 230\, \text{mH}$, $f_d = 60.0\, \text{Hz}$, and $\bar{E}_m = 36.0\, \text{V}$. What are (a) $Z$, (b) $\phi$, and (c) $I$? (d) Draw a phasor diagram.

**44** An ac generator with emf amplitude $\bar{E}_m = 220\, \text{V}$ and operating at frequency 400 Hz causes oscillations in a series $RLC$ circuit having $R = 220\, \Omega$, $L = 150\, \text{mH}$, and $C = 24.0\, \mu\text{F}$. Find (a) the capacitive reactance $X_C$, (b) the impedance $Z$, and (c) the current amplitude $I$. A second capacitor of the same capacitance is then connected in series with the other components. Determine whether the values of (d) $X_C$, (e) $Z$, and (f) $I$ increase, decrease, or remain the same.

**45** In an $RLC$ circuit, can the amplitude of the voltage across an inductor be greater than the amplitude of the generator emf? (b) Consider an $RLC$ circuit with emf amplitude $\bar{E}_m = 10\, \text{V}$, resistance $R = 10\, \Omega$, inductance $L = 1.0\, \text{H}$, and capacitance $C = 1.0\, \mu\text{F}$. Find the amplitude of the voltage across the inductor at resonance.

**46** An alternating emf source with a variable frequency $f_d$ is connected in series with a 50.0 $\Omega$ resistor and a 20.0 $\mu\text{F}$ capacitor. The emf amplitude is 12.0 V. (a) Draw a phasor diagram for phasor $V_R$ (the potential across the resistor) and phasor $V_L$ (the potential across the inductor). (b) At what driving frequency $f_d$ do the two phasors have the same length? At that driving frequency, what are (c) the phase angle in degrees, (d) the angular speed at which the phasors rotate, and (e) the current amplitude?

**47** An $RLC$ circuit such as that of Fig. 31-7 has $R = 5.00\, \Omega$, $C = 20.0\, \mu\text{F}$, $L = 1.00\, \text{H}$, and $\bar{E}_m = 30.0\, \text{V}$. (a) At what angular frequency $\omega_l$ will the current amplitude have its maximum value, as in the resonance curves of Fig. 31-16? (b) What is this maximum value? At what (c) lower angular frequency $\omega_d$ and (d) higher angular frequency $\omega_u$ will the current amplitude be half this maximum value? (e) For the resonance curve for this circuit, what is the fractional half-width $(\omega_u - \omega_d)/\omega_d$?

**48** Figure 31-32 shows a driven $RLC$ circuit that contains two identical capacitors and two switches. The emf amplitude is set at 12.0 V, and the driving frequency is set at 60.0 Hz. With both switches open, the current leads the emf by 30.9°. With switch $S_1$ closed and switch $S_2$ still open, the emf leads the current by 15.0°. With both switches closed, the current amplitude is 447 mA. What are (a) $R$, (b) $C$, and (c) $L$?

**49** In Fig. 31-33, a generator with an adjustable frequency of oscillation is connected to resistance $R = 100\, \Omega$, inductances $L_1 = 1.70\, \text{mH}$ and $L_2 = 2.30\, \text{mH}$, and capacitances $C_1 = 4.00\, \mu\text{F}$, $C_2 = 2.50\, \mu\text{F}$, and $C_3 = 3.50\, \mu\text{F}$. (a) What is the resonant frequency of the circuit? (Hint: See Problem 47 in Chapter 30.) What happens to the resonant frequency if (b) $R$ is increased, (c) $L_1$ is increased, and (d) $C_3$ is removed from the circuit?

**50** An alternating emf source with a variable frequency $f_d$ is connected in series with an 80.0 $\Omega$ resistor and a 40.0 $\mu\text{H}$ inductor. The emf amplitude is 6.00 V. (a) Draw a phasor diagram for phasor $V_R$ (the potential across the resistor) and phasor $V_L$ (the potential across the inductor). (b) At what driving frequency $f_d$ do the two phasors have the same length? At that driving frequency, what are (c) the phase angle in degrees, (d) the angular speed at which the phasors rotate, and (e) the current amplitude?

**51** The fractional half-width $\Delta\omega_c/\omega_c$ of a resonance curve, such as the ones in Fig. 31-16, is the width of the curve at half the maximum value of $I$. Show that $\Delta\omega_c/\omega_c = R(3C/L)^{1/2}$, where $\omega_c$ is the angular frequency at resonance. Note that the ratio $\Delta\omega_c/\omega_c$ increases with $R$, as Fig. 31-16 shows.

**Module 31-5 Power in Alternating-Current Circuits**

**52** An ac voltmeter with large impedance is connected in turn across the inductor, the capacitor, and the resistor in a series circuit having an alternating emf of 100 V (rms); the meter gives the same reading in volts in each case. What is this reading?

**53** An air conditioner connected to a 120 V rms ac line is equivalent to a 12.0 $\Omega$ resistance and a 1.30 $\Omega$ inductive reactance in series. Calculate (a) the impedance of the air conditioner and (b) the average rate at which energy is supplied to the appliance.

**54** What is the maximum value of an ac voltage whose rms value is 100 V?

**55** What direct current will produce the same amount of thermal energy, in a particular resistor, as an alternating current that has a maximum value of 2.60 A?

**56** A typical light dimmer used to dim the stage lights in a theater consists of a variable inductor $L$ (whose inductance is adjustable between zero and $L_{\text{max}}$) connected in series with a lightbulb $B$, as shown in Fig. 31-34. The electrical supply is 120 V (rms) at 60.0 Hz; the lightbulb is rated at 120 V, 1000 W. (a) What $L_{\text{max}}$ is required if the rate of energy dissipation in the lightbulb is to be varied by a factor of 5 from its upper limit of 1000 W? Assume that the resistance of the lightbulb is independent of its temperature. (b) Could one use a variable resistor (adjustable between zero and $R_{\text{max}}$) instead of an inductor? (c) If so, what $R_{\text{max}}$ is required? (d) Why isn’t this done?

**57** In an $RLC$ circuit such as that of Fig. 31-7 assume that $R = 5.00\, \Omega$, $L = 60.0\, \text{mH}$, $f_d = 60.0\, \text{Hz}$, and $\bar{E}_m = 30.0\, \text{V}$. For what values of the capacitance would the average rate at which energy is dissipated in the resistance be (a) a maximum and (b) a minimum? What are (c) the maximum dissipation rate and the corresponding
d) phase angle and (e) power factor? What are (f) the minimum
dissipation rate and the corresponding (g) phase angle and
(h) power factor?

65 For Fig. 31-35, show that the average rate at which energy is dissipated
in resistance $R$ is a maximum when $R$ is
equal to the internal resistance $r$ of the
ac generator. (In the text discussion we
tacitly assumed that $r = 0$.)

66 In Fig. 31-7, $R = 15.0 \, \Omega$, $C =
4.70 \, \mu F$, and $L = 25.0 \, mH$. The generator
provides an emf with rms voltage
$75.0 \, V$ and frequency $550 \, Hz$. (a) What is the rms current? What is
the rms voltage across (b) $R$, (c) $C$, (d) $L$, (e) $C$ and $L$ together, and
(f) $R$, $C$, and $L$ together? At what average rate is energy dissipated
by (g) $R$, (h) $C$, and (i) $L$?

67 An ac generator produces emf to a resistive load in a remote
factory over a two-cable transmission line. At the factory a step-
down transformer reduces the voltage from its (rms) transmission value $V_t$ to a much lower value that is safe and convenient for use
in the factory. The transmission line resistance is 0.30 $\Omega$, and
the power of the generator is 250 kW. If $V_t = 80.0 \, V$, what are
(a) the voltage decrease $\Delta V$ along the transmission line and (b) the
rate $P_d$ at which energy is dissipated in the line as thermal energy?
If $V_t = 8.00 \, V$, what are (c) $\Delta V$ and (d) $P_d$? If $V_t = 0.80 \, kW$, what are
(e) $\Delta V$ and (f) $P_d$?

Additional Problems

66 In Fig. 31-35, let the rectangular box on the left represent the
(high-impedance) output of an audio amplifier, with $r = 1000 \, \Omega$. Let
$R = 10 \, \Omega$ represent the (low-impedance) coil of a loud-
speaker. For maximum transfer of energy to the load $R$ we must have $R = r$, and that is not true in this case.
However, a transformer can be used to “transform” resistances, making them be-
have electrically as if they were larger or smaller than they actu-
ally are. (a) Sketch the primary and secondary coils of a transformer that can be introduced between the amplifier and
the speaker in Fig. 31-35 to match the impedances. (b) What must
be the turns ratio?

69 A generator of frequency 3000 Hz drives a series $RLC$ circuit
with an emf amplitude of 120 V. The resistance is 40.0 $\Omega$, the capacitance is 1.60 $\mu F$, and the inductance is 850 $\mu H$. What are (a) the
phase constant in radians and (b) the current amplitude? (c) Is the
circuit capacitive, inductive, or in resonance?

70 A 45.0 $mH$ inductor has a reactance of 1.30 $k\Omega$. (a) What is its
operating frequency? (b) What is the capacitance of a capacitor with
the same reactance at that frequency? If the frequency is doubled,
what is the new reactance of (c) the inductor and (d) the capacitor?

71 An $RLC$ circuit is driven by a generator with an emf
amplitude of 80.0 $V$ and a current amplitude of 1.25 $A$. The
current leads the emf by 0.650 rad. What are the (a) impedance
and (b) resistance of the circuit? (c) Is the circuit inductive, capaci-
tive, or in resonance?

72 A series $RLC$ circuit is driven in such a way that the maxi-
mum voltage across the inductor is 1.50 times the maximum volt-
age across the capacitor and 2.00 times the maximum voltage
across the resistor. (a) What is $\phi$ for the circuit? (b) Is the circuit

**Module 31-6 Transformers**

62 A generator supplies 100 $V$ to a transformer’s primary coil,
which has 50 turns. If the secondary coil has 500 turns, what is the
secondary voltage?

63 A transformer has 500 primary turns and 10 sec-
ondary turns. (a) If $V_p$ is 120 $V$ (rms), what is $V_s$ with an open
 circuit? If the secondary now has a resistive
load of 15 $\Omega$, what is the current in the (b)
primary and (c) secondary?

64 Figure 31-37 shows an “autotrans-
former.” It consists of a single coil (with an
iron core). Three taps $T_1$ are provided.
Between taps $T_1$ and $T_2$ there are 200 turns,
and between taps $T_2$ and $T_3$ there are 800
turns. Any two taps can be chosen as the
primary terminals, and any two taps can be
chosen as the secondary terminals. For

**Figure 31-35 Problems 58 and 66.**

**Figure 31-36 Problem 61.**

**Figure 31-37 Problem 64.**

**Figure 31-35**
inductive, capacitive, or in resonance? The resistance is 49.9 Ω, and the current amplitude is 200 mA. (c) What is the amplitude of the driving emf?

73 A capacitor of capacitance 158 μF and an inductor form an \( L/C \) circuit that oscillates at 8.15 kHz, with a current amplitude of 4.21 mA. What are (a) the inductance, (b) the total energy in the circuit, and (c) the maximum charge on the capacitor?

74 An oscillating \( L/C \) circuit has an inductance of 3.00 mH and a capacitance of 10.0 μF. Calculate the (a) angular frequency and (b) period of the oscillation. (c) At time \( t = 0 \), the capacitor is charged to 200 μC and the current is zero. Roughly sketch the charge on the capacitor as a function of time.

75 For a certain driven series \( R/L/C \) circuit, the maximum generator emf is 125 V and the maximum current is 3.20 A. If the current leads the generator emf by 0.982 rad, what are the (a) impedance and (b) resistance of the circuit? (c) Is the circuit predominantly capacitive or inductive?

76 A 1.50 μF capacitor has a capacitive reactance of 12.0 Ω. (a) What must be its operating frequency? (b) Will it be the capacitive reactance if the frequency is doubled?

77 \( \text{SSM} \) In Fig. 31-38, a three-phase generator G produces electrical power that is transmitted by means of three wires. The electric potentials (each relative to a common reference level) are \( V_1 = A \sin \omega_d t \) for wire 1, \( V_2 = A \sin(\omega_d t - 120°) \) for wire 2, and \( V_3 = A \sin(\omega_d t - 240°) \) for wire 3. Some types of industrial equipment (for example, motors) have three terminals and are designed to be connected directly to these three wires. To use a more conventional two-terminal device (for example, a lightbulb), one connects it to any two of the three wires. Show that the potential difference between any two of the wires (a) oscillates sinusoidally with angular frequency \( \omega_d \) and (b) has an amplitude of \( A \sqrt{3} \).

78 An electric motor connected to a 120 V, 60.0 Hz ac outlet does mechanical work at the rate of 0.100 hp (1 hp = 746 W). (a) If the motor draws an rms current of 0.650 A, what is its effective resistance, relative to power transfer? (b) Is this the same as the resistance of the motor’s coils, as measured with an ohmmeter with the motor disconnected from the outlet?

79 \( \text{SSM} \) (a) In an oscillating \( L/C \) circuit, in terms of the maximum charge \( Q \) on the capacitor, what is the charge there when the energy in the electric field is 50.0% of that in the magnetic field? (b) What fraction of a period must elapse following the time the capacitor is fully charged for this condition to occur?

80 A series \( R/L/C \) circuit is driven by an alternating source at a frequency of 400 Hz and an emf amplitude of 90.0 V. The resistance is 20.0 Ω, the capacitance is 12.1 μF, and the inductance is 24.2 mH. What is the rms potential difference across (a) the resistor, (b) the capacitor, and (c) the inductor? (d) What is the average rate at which energy is dissipated?

81 \( \text{SSM} \) In a certain series \( R/L/C \) circuit being driven at a frequency of 60.0 Hz, the maximum voltage across the inductor is 2.00 times the maximum voltage across the resistor and 2.00 times the maximum voltage across the capacitor. (a) By what angle does the current lag the generator emf? (b) If the maximum generator emf is 30.0 V, what should be the resistance of the circuit to obtain a maximum current of 300 mA?

82 A 1.50 mH inductor in an oscillating \( L/C \) circuit stores a maximum energy of 10.0 μJ. What is the maximum current?

83 A generator with an adjustable frequency of oscillation is wired in series to an inductor of \( L = 2.50 \text{ mH} \) and a capacitor of \( C = 3.00 \mu \text{F} \). At what frequency does the generator produce the largest possible current amplitude in the circuit?

84 A series \( R/L/C \) circuit has a resonant frequency of 6.00 kHz. When it is driven at 8.00 kHz, it has an impedance of 1.00 kΩ and a phase constant of 45°. What are (a) \( R \), (b) \( L \), and (c) \( C \) for this circuit?

85 \( \text{SSM} \) An \( L/C \) circuit oscillates at a frequency of 10.4 kHz. (a) If the capacitance is 340 μF, what is the inductance? (b) If the maximum current is 7.20 mA, what is the total energy in the circuit? (c) What is the maximum charge on the capacitor?

86 When under load and operating at an rms voltage of 220 V, a certain electric motor draws an rms current of 3.00 A. It has a resistance of 24.0 Ω and no capacitive reactance. What is its inductive reactance?

87 The ac generator in Fig. 31-39 supplies 120 V at 60.0 Hz. With the switch open as in the diagram, the current leads the generator emf by 20.0°. With the switch in position 1, the current lags the generator emf by 10.0°. When the switch is in position 2, the current amplitude is 2.00 A. What are (a) \( R \), (b) \( L \), and (c) \( C \)?

88 In an oscillating \( L/C \) circuit, \( L = 8.00 \text{ mH} \) and \( C = 1.40 \mu \text{F} \). At time \( t = 0 \), the current is maximum at 12.0 mA. (a) What is the maximum charge on the capacitor during the oscillations? (b) At what earliest time \( t > 0 \) is the rate of change of energy in the capacitor maximum? (c) What is that maximum rate of change?

89 \( \text{SSM} \) For a sinusoidally driven series \( R/L/C \) circuit, show that over one complete cycle with period \( T \) (a) the energy stored in the capacitor does not change; (b) the energy stored in the inductor does not change; (c) the driving emf device supplies energy \( \frac{1}{2}T \varepsilon_i \omega \cos \phi \); and (d) the resistor dissipates energy \( \frac{1}{2}T R \Omega \). (e) Show that the quantities found in (c) and (d) are equal.

90 What capacitance would you connect across a 1.30 mH inductor to make the resulting oscillator resonate at 3.50 kHz?

91 A series circuit with resistor–inductor–capacitor combination \( R_1, L_1, C_1 \) has the same resonant frequency as a second circuit with a different combination \( R_2, L_2, C_2 \). You now connect the two combinations in series. Show that this new circuit has the same resonant frequency as the separate circuits.

92 Consider the circuit shown in Fig. 31-40. With switch \( S_1 \) closed and the other two switches open, the circuit has a time constant \( \tau_1 \). With switch \( S_2 \) closed and the other two switches open, the circuit has a time constant \( \tau_2 \). With switch \( S_3 \) closed and the other two switches open, the circuit oscillates with a period \( T \). Show that \( T = 2 \pi \sqrt{\tau_1 \tau_2} \).

93 When the generator emf in Sample Problem 31.07 is a maximum, what is the voltage across (a) the generator, (b) the resistance, (c) the capacitance, and (d) the inductance? (e) By summing these with appropriate signs, verify that the loop rule is satisfied.
Gauss' Law for Magnetic Fields

Learning Objectives

32.01 Identify that the simplest magnetic structure is a magnetic dipole.
32.02 Calculate the magnetic flux through a surface by integrating the dot product of the magnetic field vector $\vec{B}$ and the area vector $d\vec{A}$ (for patch elements) over the surface.
32.03 Identify that the net magnetic flux through a Gaussian surface (which is a closed surface) is zero.

Key Idea

The simplest magnetic structures are magnetic dipoles. Magnetic monopoles do not exist (as far as we know). Gauss' law for magnetic fields,

$$\Phi_B = \oint \vec{B} \cdot d\vec{A} = 0,$$

states that the net magnetic flux through any (closed) Gaussian surface is zero. It implies that magnetic monopoles do not exist.

What Is Physics?

This chapter reveals some of the breadth of physics because it ranges from the basic science of electric and magnetic fields to the applied science and engineering of magnetic materials. First, we conclude our basic discussion of electric and magnetic fields, finding that most of the physics principles in the last 11 chapters can be summarized in only four equations, known as Maxwell's equations.

Second, we examine the science and engineering of magnetic materials. The careers of many scientists and engineers are focused on understanding why some materials are magnetic and others are not and on how existing magnetic materials can be improved. These researchers wonder why Earth has a magnetic field but you do not. They find countless applications for inexpensive magnetic materials in cars, kitchens, offices, and hospitals, and magnetic materials often show up in unexpected ways. For example, if you have a tattoo (Fig. 32-1) and undergo an MRI (magnetic resonance imaging) scan, the large magnetic field used in the scan may noticeably tug on your tattooed skin because some tattoo inks contain magnetic particles. In another example, some breakfast cereals are advertised as being “iron fortified” because they contain small bits of iron for you to ingest. Because these iron bits are magnetic, you can collect them by passing a magnet over a slurry of water and cereal.

Our first step here is to revisit Gauss' law, but this time for magnetic fields.
Gauss’ Law for Magnetic Fields

Figure 32-2 shows iron powder that has been sprinkled onto a transparent sheet placed above a bar magnet. The powder grains, trying to align themselves with the magnet’s magnetic field, have fallen into a pattern that reveals the field. One end of the magnet is a source of the field (the field lines diverge from it) and the other end is a sink of the field (the field lines converge toward it). By convention, we call the source the north pole of the magnet and the sink the south pole, and we say that the magnet, with its two poles, is an example of a magnetic dipole.

Suppose we break a bar magnet into pieces the way we can break a piece of chalk (Fig. 32-3). We should, it seems, be able to isolate a single magnetic pole, called a magnetic monopole. However, we cannot—not even if we break the magnet down to its individual atoms and then to its electrons and nuclei. Each fragment has a north pole and a south pole. Thus:

The simplest magnetic structure that can exist is a magnetic dipole. Magnetic monopoles do not exist (as far as we know).

Gauss’ law for magnetic fields is a formal way of saying that magnetic monopoles do not exist. The law asserts that the net magnetic flux \( \Phi_B \) through any closed Gaussian surface is zero:

\[
\Phi_B = \oint \mathbf{B} \cdot d\mathbf{A} = 0 \quad \text{(Gauss’ law for magnetic fields).} \tag{32-1}
\]

Contrast this with Gauss’ law for electric fields,

\[
\Phi_E = \oint \mathbf{E} \cdot d\mathbf{A} = \frac{q_{\text{enc}}}{\epsilon_0} \quad \text{(Gauss’ law for electric fields).}
\]

In both equations, the integral is taken over a closed Gaussian surface. Gauss’ law for electric fields says that this integral (the net electric flux through the surface) is proportional to the net electric charge \( q_{\text{enc}} \) enclosed by the surface. Gauss’ law for magnetic fields says that there can be no net magnetic flux through the surface because there can be no net “magnetic charge” (individual magnetic poles) enclosed by the surface. The simplest magnetic structure that can exist and thus be enclosed by a Gaussian surface is a dipole, which consists of both a source and a sink for the field lines. Thus, there must always be as much magnetic flux into the surface as out of it, and the net magnetic flux must always be zero.

Gauss’ law for magnetic fields holds for structures more complicated than a magnetic dipole, and it holds even if the Gaussian surface does not enclose the entire structure. Gaussian surface II near the bar magnet of Fig. 32-4 encloses no poles, and we can easily conclude that the net magnetic flux through it is zero. Gaussian surface I is more difficult. It may seem to enclose only the north pole of the magnet because it encloses the label N and not the label S. However, a south pole must be associated with the lower boundary of the surface because magnetic field lines enter the surface there. (The enclosed section is like one piece of the broken bar magnet in Fig. 32-3.) Thus, Gaussian surface I encloses a magnetic dipole, and the net flux through the surface is zero.

Figure 32-2 A bar magnet is a magnetic dipole. The iron filings suggest the magnetic field lines. (Colored light fills the background.)

Figure 32-3 If you break a magnet, each fragment becomes a separate magnet, with its own north and south poles.

Figure 32-4 The field lines for the magnetic field \( \mathbf{B} \) of a short bar magnet. The red curves represent cross sections of closed, three-dimensional Gaussian surfaces.
Checkpoint 1

The figure here shows four closed surfaces with flat top and bottom faces and curved sides. The table gives the areas $A$ of the faces and the magnitudes $B$ of the uniform and perpendicular magnetic fields through those faces; the units of $A$ and $B$ are arbitrary but consistent. Rank the surfaces according to the magnitudes of the magnetic flux through their curved sides, greatest first.

32-2 INDUCTED MAGNETIC FIELDS

Learning Objectives

After reading this module, you should be able to . . .

32.04 Identify that a changing electric flux induces a magnetic field.
32.05 Apply Maxwell's law of induction to relate the magnetic field induced around a closed loop to the rate of change of electric flux encircled by the loop.
32.06 Draw the field lines for an induced magnetic field inside a capacitor with parallel circular plates that are being charged, indicating the orientations of the vectors for the electric field and the magnetic field.
32.07 For the general situation in which magnetic fields can be induced, apply the Ampere–Maxwell (combined) law.

Key Ideas

- A changing electric flux induces a magnetic field $\vec{B}$.
- Maxwell's law,
  \[ \oint \vec{B} \cdot d\vec{s} = \mu_0 \epsilon_0 \frac{d\Phi_E}{dt} \] (Maxwell's law of induction),
  relates the magnetic field induced along a closed loop to the changing electric flux $\Phi_E$ through the loop.
- Ampere's law, $\oint \vec{B} \cdot d\vec{s} = \mu_0 i_{\text{enc}}$ gives the magnetic field generated by a current $i_{\text{enc}}$ encircled by a closed loop.
- Maxwell's law and Ampere's law can be written as the single equation
  \[ \oint \vec{B} \cdot d\vec{s} = \mu_0 \epsilon_0 \frac{d\Phi_E}{dt} + \mu_0 i_{\text{enc}} \] (Ampere–Maxwell law).

Induced Magnetic Fields

In Chapter 30 you saw that a changing magnetic flux induces an electric field, and we ended up with Faraday's law of induction in the form

\[ \oint \vec{E} \cdot d\vec{s} = -\frac{d\Phi_B}{dt} \] (Faraday's law of induction).  \hspace{1cm} (32-2)

Here $\vec{E}$ is the electric field induced along a closed loop by the changing magnetic flux $\Phi_B$ encircled by that loop. Because symmetry is often so powerful in physics, we should be tempted to ask whether induction can occur in the opposite sense; that is, can a changing electric flux induce a magnetic field?

The answer is that it can; furthermore, the equation governing the induction of a magnetic field is almost symmetric with Eq. 32-2. We often call it Maxwell's
law of induction after James Clerk Maxwell, and we write it as

$$\int \vec{B} \cdot d\vec{s} = \mu_0 \rho_0 \frac{d\Phi_E}{dt}$$  \hspace{1em} (Maxwell’s law of induction).  \hspace{1em} (32-3)$$

Here $\vec{B}$ is the magnetic field induced along a closed loop by the changing electric flux $\Phi_E$ in the region encircled by that loop.

**Charging a Capacitor.** As an example of this sort of induction, we consider the charging of a parallel-plate capacitor with circular plates. (Although we shall focus on this arrangement, a changing electric flux will always induce a magnetic field whenever it occurs.) We assume that the charge on our capacitor (Fig. 32-5a) is being increased at a steady rate by a constant current $i$ in the connecting wires. Then the electric field magnitude between the plates must also be increasing at a steady rate.

Figure 32-5b is a view of the right-hand plate of Fig. 32-5a from between the plates. The electric field is directed into the page. Let us consider a circular loop through point 1 in Figs. 32-5a and b, a loop that is concentric with the capacitor plates and has a radius smaller than that of the plates. Because the electric field through the loop is changing, the electric flux through the loop must also be changing. According to Eq. 32-3, this changing electric flux induces a magnetic field around the loop.

Experiment proves that a magnetic field $\vec{B}$ is indeed induced around such a loop, directed as shown. This magnetic field has the same magnitude at every point around the loop and thus has circular symmetry about the central axis of the capacitor plates (the axis extending from one plate center to the other).

If we now consider a larger loop—say, through point 2 outside the plates in Figs. 32-5a and b—we find that a magnetic field is induced around that loop as well. Thus, while the electric field is changing, magnetic fields are induced between the plates, both inside and outside the gap. When the electric field stops changing, these induced magnetic fields disappear.

Although Eq. 32-3 is similar to Eq. 32-2, the equations differ in two ways. First, Eq. 32-3 has the two extra symbols $\mu_0$ and $\rho_0$, but they appear only because we employ SI units. Second, Eq. 32-3 lacks the minus sign of Eq. 32-2, meaning that the induced electric field $\vec{E}$ and the induced magnetic field $\vec{B}$ have opposite directions when they are produced in otherwise similar situations. To see this opposition, examine Fig. 32-6, in which an increasing magnetic field $\vec{B}$, directed into the page, induces an electric field $\vec{E}$. The induced field $\vec{E}$ is counterclockwise, opposite the induced magnetic field $\vec{B}$ in Fig. 32-5b.

**Ampere–Maxwell Law**

Now recall that the left side of Eq. 32-3, the integral of the dot product $\vec{B} \cdot d\vec{s}$ around a closed loop, appears in another equation—namely, Ampere’s law:

$$\oint \vec{B} \cdot d\vec{s} = \mu_0 \iota_{\text{enc}}$$  \hspace{1em} (Ampere’s law),  \hspace{1em} (32-4)$$

**Figure 32-5** (a) A circular parallel-plate capacitor, shown in side view, is being charged by a constant current $i$. (b) A view from within the capacitor, looking toward the plate at the right in (a). The electric field $\vec{E}$ is uniform, is directed into the page (toward the plate), and grows in magnitude as the charge on the capacitor increases. The magnetic field $\vec{B}$ induced by this changing electric field is shown at four points on a circle with a radius $r$ less than the plate radius $R$.

**Figure 32-6** A uniform magnetic field $\vec{B}$ in a circular region. The field, directed into the page, is increasing in magnitude. The electric field $\vec{E}$ induced by the changing magnetic field is shown at four points on a circle concentric with the circular region. Compare this situation with that of Fig. 32-5b.
where \( i_{\text{enc}} \) is the current encircled by the closed loop. Thus, our two equations that specify the magnetic field \( \vec{B} \) produced by means other than a magnetic material (that is, by a current and by a changing electric field) give the field in exactly the same form. We can combine the two equations into the single equation

\[
\oint \vec{B} \cdot d\vec{s} = \mu_0 \varepsilon_0 \frac{d\Phi_E}{dt} + \mu_0 i_{\text{enc}} \quad \text{(Ampere – Maxwell law).} \tag{32-5}
\]

When there is a current but no change in electric flux (such as with a wire carrying a constant current), the first term on the right side of Eq. 32-5 is zero, and so Eq. 32-5 reduces to Eq. 32-4, Ampere’s law. When there is a change in electric flux but no current (such as inside or outside the gap of a charging capacitor), the second term on the right side of Eq. 32-5 is zero, and so Eq. 32-5 reduces to Eq. 32-3, Maxwell’s law of induction.

**Checkpoint 2**

The figure shows graphs of the electric field magnitude \( E \) versus time \( t \) for four uniform electric fields, all contained within identical circular regions as in Fig. 32-5b. Rank the fields according to the magnitudes of the magnetic fields they induce at the edge of the region, greatest first.

**Sample Problem 32.01  Magnetic field induced by changing electric field**

A parallel-plate capacitor with circular plates of radius \( R \) is being charged as in Fig. 32-5a.

(a) Derive an expression for the magnetic field at radius \( r \) for the case \( r \leq R \).

**KEY IDEAS**

A magnetic field can be set up by a current and by induction due to a changing electric flux; both effects are included in Eq. 32-5. There is no current between the capacitor plates of Fig. 32-5, but the electric flux there is changing. Thus, Eq. 32-5 reduces to

\[
\oint \vec{B} \cdot d\vec{s} = \mu_0 \varepsilon_0 \frac{d\Phi_E}{dt}. \tag{32-6}
\]

We shall separately evaluate the left and right sides of this equation.

**Left side of Eq. 32-6:** We choose a circular Amperian loop with a radius \( r \leq R \) as shown in Fig. 32-5b because we want to evaluate the magnetic field for \( r \leq R \) — that is, inside the capacitor. The magnetic field \( \vec{B} \) at all points along the loop is tangent to the loop, as is the path element \( d\vec{s} \). Thus, \( \vec{B} \) and \( d\vec{s} \) are either parallel or antiparallel at each point of the loop. For simplicity, assume they are parallel (the choice does not alter our outcome here). Then

\[
\oint \vec{B} \cdot d\vec{s} = \oint B \, ds \cos 0^\circ = \oint B \, ds.
\]

Due to the circular symmetry of the plates, we can also assume that \( \vec{B} \) has the same magnitude at every point around the loop. Thus, \( B \) can be taken outside the integral on the right side of the above equation. The integral that remains is \( \oint B \, ds \), which simply gives the circumference \( 2\pi r \) of the loop. The left side of Eq. 32-6 is then \( (B)(2\pi r) \).

**Right side of Eq. 32-6:** We assume that the electric field \( \vec{E} \) is uniform between the capacitor plates and directed perpendicular to the plates. Then the electric flux \( \Phi_E \) through the Amperian loop is \( EA \), where \( A \) is the area encircled by the loop within the electric field. Thus, the right side of Eq. 32-6 is \( \mu_0 \varepsilon_0 \frac{d(EA)}{dt} \).

**Combining results:** Substituting our results for the left and right sides into Eq. 32-6, we get

\[
(B)(2\pi r) = \mu_0 \varepsilon_0 \frac{d(EA)}{dt}.
\]

Because \( A \) is a constant, we write \( d(EA) \) as \( dE \); so we have

\[
(B)(2\pi r) = \mu_0 \varepsilon_0 A \frac{dE}{dt}. \tag{32-7}
\]

The area \( A \) that is encircled by the Amperian loop within the electric field is the full area \( \pi r^2 \) of the loop because the loop’s radius \( r \) is less than (or equal to) the plate radius \( R \). Substituting \( \pi r^2 \) for \( A \) in Eq. 32-7 leads to, for \( r \leq R \),

\[
B = \frac{\mu_0 \varepsilon_0 r^2}{2} \frac{dE}{dt}. \quad \text{(Answer) (32-8)}
\]
This equation tells us that, inside the capacitor, \( B \) increases linearly with increased radial distance \( r \), from 0 at the central axis to a maximum value at plate radius \( R \).

(b) Evaluate the field magnitude \( B \) for \( r = R/5 = 11.0 \text{ mm} \) and \( dE/dt = 1.50 \times 10^{12} \text{ V/m} \cdot \text{s} \).

**Calculation:** From the answer to (a), we have

\[
B = \frac{1}{2} \mu_0 \varepsilon_0 r \frac{dE}{dt} = \frac{1}{2} (4\pi \times 10^{-7} \text{ T} \cdot \text{m/A}) \times (11.0 \times 10^{-3} \text{ m}) (1.50 \times 10^{12} \text{ V/m} \cdot \text{s})
\]

\[
= 9.18 \times 10^{-8} \text{ T}.
\]

(c) Derive an expression for the induced magnetic field for the case \( r \geq R \).

**Calculation:** Our procedure is the same as in (a) except we now use an Amperian loop with a radius \( r \) that is greater than the plate radius \( R \), to evaluate \( B \) outside the capacitor. Evaluating the left and right sides of Eq. 32-6 again leads to Eq. 32-7. However, we then need this subtle point: The electric field exists only between the plates, not outside the plates. Thus, the area \( A \) that is encircled by the Amperian loop in the electric field is not the full area \( \pi r^2 \) of the loop. Rather, \( A \) is only the plate area \( \pi R^2 \).

Substituting \( \pi R^2 \) for \( A \) in Eq. 32-7 and solving the result for \( B \) gives us, for \( r \geq R \),

\[
B = \frac{\mu_0 \varepsilon_0 R^2}{2r} \frac{dE}{dt}.
\]

This equation tells us that, outside the capacitor, \( B \) decreases with increased radial distance \( r \), from a maximum value at the plate edges (where \( r = R \)). By substituting \( r = R \) into Eqs. 32-8 and 32-9, you can show that these equations are consistent; that is, they give the same maximum value of \( B \) at the plate radius.

The magnitude of the induced magnetic field calculated in (b) is so small that it can scarcely be measured with simple apparatus. This is in sharp contrast to the magnitudes of induced electric fields (Faraday’s law), which can be measured easily. This experimental difference exists partly because induced emfs can easily be multiplied by using a coil of many turns. No technique of comparable simplicity exists for multiplying induced magnetic fields. In any case, the experiment suggested by this sample problem has been done, and the presence of the induced magnetic fields has been verified quantitatively.

### 32-3 DISPLACEMENT CURRENT

**Learning Objectives**

After reading this module, you should be able to . . .

- **32.08** Identify that in the Ampere–Maxwell law, the contribution to the induced magnetic field by the changing electric flux can be attributed to a fictitious current (“displacement current”) to simplify the expression.
- **32.09** Identify that in a capacitor that is being charged or discharged, a displacement current is said to be spread uniformly over the plate area, from one plate to the other.
- **32.10** Apply the relationship between the rate of change of an electric flux and the associated displacement current.
- **32.11** For a charging or discharging capacitor, relate the amount of displacement current to the amount of actual current and identify that the displacement current exists only when the electric field within the capacitor is changing.
- **32.12** Mimic the equations for the magnetic field inside and outside a wire with real current to write (and apply) the equations for the magnetic field inside and outside a region of displacement current.
- **32.13** Apply the Ampere–Maxwell law to calculate the magnetic field of a real current and a displacement current.
- **32.14** For a charging or discharging capacitor with parallel circular plates, draw the magnetic field lines due to the displacement current.
- **32.15** List Maxwell’s equations and the purpose of each.

**Key Ideas**

- We define the fictitious displacement current due to a changing electric field as

\[
i_d = \varepsilon_0 \frac{d\Phi_E}{dt}.
\]

- The Ampere–Maxwell law then becomes

\[
\int \vec{B} \cdot d\vec{s} = \mu_0 i_{d,enc} + \mu_0 i_{enc} \quad \text{(Ampere–Maxwell law),}
\]

where \( i_{d,enc} \) is the displacement current encircled by the integration loop.

- The idea of a displacement current allows us to retain the notion of continuity of current through a capacitor. However, displacement current is not a transfer of charge.

- Maxwell’s equations, displayed in Table 32-1, summarize electromagnetism and form its foundation, including optics.
Displacement Current

If you compare the two terms on the right side of Eq. 32-5, you will see that the product \( \varepsilon_0 (d\Phi_E/dt) \) must have the dimension of a current. In fact, that product has been treated as being a fictitious current called the displacement current \( i_d \):

\[
i_d = \varepsilon_0 \frac{d\Phi_E}{dt} \quad \text{(displacement current).} \tag{32-10}
\]

“Displacement” is poorly chosen in that nothing is being displaced, but we are stuck with the word. Nevertheless, we can now rewrite Eq. 32-5 as

\[
\oint \vec{B} \cdot d\vec{s} = \mu_0 i_{d,\text{enc}} + \mu_0 i_{\text{enc}} \quad \text{(Ampere–Maxwell law),} \tag{32-11}
\]

in which \( i_{d,\text{enc}} \) is the displacement current that is encircled by the integration loop.

Let us again focus on a charging capacitor with circular plates, as in Fig. 32-7a. The real current \( i \) that is charging the plates changes the electric field \( \vec{E} \) between the plates. The fictitious displacement current \( i_d \) between the plates is associated with that changing field \( \vec{E} \). Let us relate these two currents.

The charge \( q \) on the plates at any time is related to the magnitude \( E \) of the field between the plates at that time and the plate area \( A \) by Eq. 25-4:

\[
q = \varepsilon_0 A E. \tag{32-12}
\]

To get the real current \( i \), we differentiate Eq. 32-12 with respect to time, finding

\[
\frac{dq}{dt} = i = \varepsilon_0 A \frac{dE}{dt}. \tag{32-13}
\]

To get the displacement current \( i_d \), we can use Eq. 32-10. Assuming that the electric field \( \vec{E} \) between the two plates is uniform (we neglect any fringing), we can

\[
\frac{d\Phi_E}{dt} = \frac{1}{2} \mu_0 \varepsilon_0 A \frac{dE}{dt}.
\]

Figure 32-7 (a) Before and (d) after the plates are charged, there is no magnetic field. (b) During the charging, magnetic field is created by both the real current and the (fictional) displacement current. (c) The same right-hand rule works for both currents to give the direction of the magnetic field.
replace the electric flux $\Phi_E$ in that equation with $EA$. Then Eq. 32-10 becomes

$$i_d = \varepsilon_0 \frac{d\Phi_E}{dt} = \varepsilon_0 \frac{d(EA)}{dt} = \varepsilon_0 A \frac{dE}{dt}. \quad (32-14)$$

**Same Value.** Comparing Eqs. 32-13 and 32-14, we see that the real current $i$ charging the capacitor and the fictitious displacement current $i_d$ between the plates have the same value:

$$i_d = i \quad \text{(displacement current in a capacitor).} \quad (32-15)$$

Thus, we can consider the fictitious displacement current $i_d$ to be simply a continuation of the real current $i$ from one plate, across the capacitor gap, to the other plate. Because the electric field is uniformly spread over the plates, the same is true of this fictitious displacement current $i_d$, as suggested by the spread of current arrows in Fig. 32-7b. Although no charge actually moves across the gap between the plates, the idea of the fictitious current $i_d$ can help us to quickly find the direction and magnitude of an induced magnetic field, as follows.

**Finding the Induced Magnetic Field**

In Chapter 29 we found the direction of the magnetic field produced by a real current $i$ by using the right-hand rule of Fig. 29-5. We can apply the same rule to find the direction of an induced magnetic field produced by a fictitious displacement current $i_d$, as is shown in the center of Fig. 32-7c for a capacitor.

We can also use $i_d$ to find the magnitude of the magnetic field induced by a charging capacitor with parallel circular plates of radius $R$. We simply consider the space between the plates to be an imaginary circular wire of radius $R$ carrying the imaginary current $i_d$. Then, from Eq. 29-20, the magnitude of the magnetic field at a point inside the capacitor at radius $r$ from the center is

$$B = \left( \frac{\mu_0 i_d}{2\pi r} \right) r \quad \text{(inside a circular capacitor).} \quad (32-16)$$

Similarly, from Eq. 29-17, the magnitude of the magnetic field at a point outside the capacitor at radius $r$ is

$$B = \frac{\mu_0 i_d}{2\pi r} \quad \text{(outside a circular capacitor).} \quad (32-17)$$

**Checkpoint 3**

The figure is a view of one plate of a parallel-plate capacitor from within the capacitor. The dashed lines show four integration paths (path $b$ follows the edge of the plate). Rank the paths according to the magnitude of $\oint \vec{B} \cdot d\vec{s}$ along the paths during the discharging of the capacitor, greatest first.

---

**Sample Problem 32.02**  **Treating a changing electric field as a displacement current**

A circular parallel-plate capacitor with plate radius $R$ is being charged with a current $i$.

(a) Between the plates, what is the magnitude of $\oint \vec{B} \cdot d\vec{s}$, in terms of $\mu_0$ and $i$, at a radius $r = R/5$ from their center?
the changing electric flux with a fictitious displacement current \( i_d \). Then integral \( \int \vec{B} \cdot d\vec{s} \) is given by Eq. 32-11, but because there is no real current \( i \) between the capacitor plates, the equation reduces to

\[
\int \vec{B} \cdot d\vec{s} = \mu_0 i_{d,\text{enc}}. \tag{32-18}
\]

**Calculations:** Because we want to evaluate \( \int \vec{B} \cdot d\vec{s} \) at radius \( r = R/5 \) (within the capacitor), the integration loop encircles only a portion \( i_{d,\text{enc}} \) of the total displacement current \( i_d \). Let’s assume that \( i_d \) is uniformly spread over the full plate area. Then the portion of the displacement current encircled by the loop is proportional to the area encircled by the loop:

\[
\frac{\text{encircled displacement current } i_{d,\text{enc}}}{\text{total displacement current } i_d} = \frac{\text{encircled area } \pi r^2}{\text{full plate area } \pi R^2}.
\]

This gives us

\[
i_{d,\text{enc}} = i_d \frac{\pi r^2}{\pi R^2}.
\]

Substituting this into Eq. 32-18, we obtain

\[
\int \vec{B} \cdot d\vec{s} = \mu_0 i_d \frac{\pi r^2}{\pi R^2}. \tag{32-19}
\]

Now substituting \( i_d = i \) (from Eq. 32-15) and \( r = R/5 \) into Eq. 32-19 leads to

\[
\int \vec{B} \cdot d\vec{s} = \mu_0 i \frac{(R/5)^2}{R^2} = \frac{\mu_0 i}{25}. \tag{Answer}
\]

(b) In terms of the maximum induced magnetic field, what is the magnitude of the magnetic field induced at \( r = R/5 \), inside the capacitor?

**KEY IDEA**

Because the capacitor has parallel circular plates, we can treat the space between the plates as an imaginary wire of radius \( R \) carrying the imaginary current \( i_d \). Then we can use Eq. 32-16 to find the induced magnetic field magnitude \( B \) at any point inside the capacitor.

**Calculations:** At \( r = R/5 \), Eq. 32-16 yields

\[
B = \left( \frac{\mu_0 i_d}{2 \pi R^2} \right) r = \frac{\mu_0 i_d (R/5)}{2 \pi R^2} = \frac{\mu_0 i_d}{10 \pi R}. \tag{32-20}
\]

From Eq. 32-16, the maximum field magnitude \( B_{\text{max}} \) within the capacitor occurs at \( r = R \). It is

\[
B_{\text{max}} = \left( \frac{\mu_0 i_d}{2 \pi R^2} \right) R = \frac{\mu_0 i_d}{2 \pi R}. \tag{32-21}
\]

Dividing Eq. 32-20 by Eq. 32-21 and rearranging the result, we find that the field magnitude at \( r = R/5 \) is

\[
B = \frac{1}{5} B_{\text{max}}. \tag{Answer}
\]

We should be able to obtain this result with a little reasoning and less work. Equation 32-16 tells us that inside the capacitor, \( B \) increases linearly with \( r \). Therefore, a point \( \frac{1}{5} \) the distance out to the full radius \( R \) of the plates, where \( B_{\text{max}} \) occurs, should have a field \( B \) that is \( \frac{1}{5} B_{\text{max}} \).

---

**Maxwell’s Equations**

Equation 32-5 is the last of the four fundamental equations of electromagnetism, called Maxwell’s equations and displayed in Table 32-1. These four equations

explain a diverse range of phenomena, from why a compass needle points north to why a car starts when you turn the ignition key. They are the basis for the functioning of such electromagnetic devices as electric motors, television transmitters and receivers, telephones, scanners, radar, and microwave ovens.

Maxwell’s equations are the basis from which many of the equations you have seen since Chapter 21 can be derived. They are also the basis of many of the equations you will see in Chapters 33 through 36 concerning optics.

32-4 MAGNETS

Learning Objectives

After reading this module, you should be able to . . .

32.16 Identify lodestones.
32.17 In Earth’s magnetic field, identify that the field is approximately that of a dipole and also identify in which hemisphere the north geomagnetic pole is located.
32.18 Identify field declination and field inclination.

Key Ideas

- Earth is approximately a magnetic dipole with a dipole axis somewhat off the rotation axis and with the south pole in the Northern Hemisphere.
- The local field direction is given by the field declination (the angle left or right from geographic north) and the field inclination (the angle up or down from the horizontal).

Magnets

The first known magnets were lodestones, which are stones that have been magnetized (made magnetic) naturally. When the ancient Greeks and ancient Chinese discovered these rare stones, they were amused by the stones’ ability to attract metal over a short distance, as if by magic. Only much later did they learn to use lodestones (and artificially magnetized pieces of iron) in compasses to determine direction.

Today, magnets and magnetic materials are ubiquitous. Their magnetic properties can be traced to their atoms and electrons. In fact, the inexpensive magnet you might use to hold a note on the refrigerator door is a direct result of the quantum physics taking place in the atomic and subatomic material within the magnet. Before we explore some of this physics, let’s briefly discuss the largest magnet we commonly use — namely, Earth itself.

The Magnetism of Earth

Earth is a huge magnet; for points near Earth’s surface, its magnetic field can be approximated as the field of a huge bar magnet — a magnetic dipole — that straddles the center of the planet. Figure 32-8 is an idealized symmetric depiction of the dipole field, without the distortion caused by passing charged particles from the Sun.

Because Earth’s magnetic field is that of a magnetic dipole, a magnetic dipole moment \( \vec{\mu} \) is associated with the field. For the idealized field of Fig. 32-8, the magnitude of \( \vec{\mu} \) is \( 8.0 \times 10^{22} \) J/T and the direction of \( \vec{\mu} \) makes an angle of 11.5° with the rotation axis \((RR)\) of Earth. The dipole axis \((MM)\) in Fig. 32-8 lies along \( \vec{\mu} \) and intersects Earth’s surface at the geomagnetic north pole off the northwest coast of Greenland and the geomagnetic south pole in Antarctica. The lines of the magnetic field \( \vec{B} \) generally emerge in the Southern Hemisphere and reenter Earth in the Northern Hemisphere. Thus, the magnetic pole that is in Earth’s Northern Hemisphere and known as a “north magnetic pole” is really the south pole of Earth’s magnetic dipole.
The direction of the magnetic field at any location on Earth's surface is commonly specified in terms of two angles. The field declination is the angle (left or right) between geographic north (which is toward 90° latitude) and the horizontal component of the field. The field inclination is the angle (up or down) between a horizontal plane and the field's direction.

Measurement. Magnetometers measure these angles and determine the field with much precision. However, you can do reasonably well with just a compass and a dip meter. A compass is simply a needle-shaped magnet that is mounted so it can rotate freely about a vertical axis. When it is held in a horizontal plane, the north-pole end of the needle points, generally, toward the geomagnetic north pole (really a south magnetic pole, remember). The angle between the needle and geographic north is the field declination. A dip meter is a similar magnet that can rotate freely about a horizontal axis. When its vertical plane of rotation is aligned with the direction of the compass, the angle between the meter's needle and the horizontal is the field inclination.

At any point on Earth's surface, the measured magnetic field may differ appreciably, in both magnitude and direction, from the idealized dipole field of Fig. 32-8. In fact, the point where the field is actually perpendicular to Earth's surface and inward is not located at the geomagnetic north pole off Greenland as we would expect; instead, this so-called dip north pole is located in the Queen Elizabeth Islands in northern Canada, far from Greenland.

In addition, the field observed at any location on the surface of Earth varies with time, by measurable amounts over a period of a few years and by substantial amounts over, say, 100 years. For example, between 1580 and 1820 the direction indicated by compass needles in London changed by 35°.

In spite of these local variations, the average dipole field changes only slowly over such relatively short time periods. Variations over longer periods can be studied by measuring the weak magnetism of the ocean floor on either side of the Mid-Atlantic Ridge (Fig. 32-9). This floor has been formed by molten magma that oozed up through the ridge from Earth's interior, solidified, and was pulled away from the ridge (by the drift of tectonic plates) at the rate of a few centimeters per year. As the magma solidified, it became weakly magnetized with its magnetic field in the direction of Earth's magnetic field at the time of solidification. Study of this solidified magma across the ocean floor reveals that Earth's field has reversed its polarity (directions of the north pole and south pole) about every million years. Theories explaining the reversals are still in preliminary stages. In fact, the mechanism that produces Earth's magnetic field is only vaguely understood.
32-5 MAGNETISM AND ELECTRONS

Learning Objectives
After reading this module, you should be able to . . .

32.19 Identify that a spin angular momentum \( \vec{S} \) (usually simply called spin) and a spin magnetic dipole moment \( \vec{\mu}_s \) are intrinsic properties of electrons (and also protons and neutrons).

32.20 Apply the relationship between the spin vector \( \vec{S} \) and the spin magnetic dipole moment vector \( \vec{\mu}_s \).

32.21 Identify that \( \vec{S} \) and \( \vec{\mu}_s \) cannot be observed (measured); only their components on an axis of measurement (usually called the z axis) can be observed.

32.22 Identify that the observed components \( S_z \) and \( \mu_{s,z} \) are quantized and explain what that means.

32.23 Apply the relationship between the component \( S_z \) and the spin magnetic quantum number \( m_s \), specifying the allowed values of \( m_s \).

32.24 Distinguish spin up from spin down for the spin orientation of an electron.

32.25 Determine the \( z \) components \( \mu_{s,z} \) of the spin magnetic dipole moment, both as a value and in terms of the Bohr magneton \( \mu_B \).

32.26 If an electron is in an external magnetic field, determine the orientation energy \( U \) of its spin magnetic dipole moment \( \vec{\mu}_s \).

32.27 Identify that an electron in an atom has an orbital angular momentum \( \vec{L}_{\text{orb}} \) and an orbital magnetic dipole moment \( \vec{\mu}_{\text{orb}} \).

32.28 Apply the relationship between the orbital angular momentum \( \vec{L}_{\text{orb}} \) and the orbital magnetic dipole moment \( \vec{\mu}_{\text{orb}} \).

32.29 Identify that \( \vec{L}_{\text{orb}} \) and \( \vec{\mu}_{\text{orb}} \) cannot be observed but their components \( L_{\text{orb},z} \) and \( \mu_{\text{orb},z} \) on a \( z \) (measurement) axis can.

32.30 Apply the relationship between the component \( L_{\text{orb},z} \) of the orbital angular momentum and the orbital magnetic quantum number \( m_\ell \), specifying the allowed values of \( m_\ell \).

32.31 Determine the \( z \) components \( \mu_{\text{orb},z} \) of the orbital magnetic dipole moment, both as a value and in terms of the Bohr magneton \( \mu_B \).

32.32 If an atom is in an external magnetic field, determine the orientation energy \( U \) of the orbital magnetic dipole moment \( \vec{\mu}_{\text{orb}} \).

32.33 Calculate the magnitude of the magnetic moment of a charged particle moving in a circle or a ring of uniform charge rotating like a merry-go-round at a constant angular speed around a central axis.

32.34 Explain the classical loop model for an orbiting electron and the forces on such a loop in a nonuniform magnetic field.

32.35 Distinguish diamagnetism, paramagnetism, and ferromagnetism.

Key Ideas

- An electron has an intrinsic angular momentum called spin angular momentum (or spin) \( \vec{S} \), with which an intrinsic spin magnetic dipole moment \( \vec{\mu}_s \) is associated:
  \[
  \vec{\mu}_s = -\frac{e}{m} \vec{S}.
  \]

- For a measurement along a \( z \) axis, the component \( S_z \) can have only the values given by
  \[
  S_z = m_s \frac{h}{2\pi}, \quad \text{for } m_s = \pm \frac{1}{2},
  \]
  where \( h = 6.63 \times 10^{-34} \text{ J} \cdot \text{s} \) is the Planck constant.

- Similarly,
  \[
  \mu_{s,z} = \pm \frac{eh}{4\pi m} = \pm \mu_B,
  \]
  where \( \mu_B \) is the Bohr magneton:
  \[
  \mu_B = \frac{eh}{4\pi m} = 9.27 \times 10^{-24} \text{ J/T}.
  \]

- The energy \( U \) associated with the orientation of the spin magnetic dipole moment in an external magnetic field \( \vec{B}_{\text{ext}} \) is
  \[
  U = -\vec{\mu}_s \cdot \vec{B}_{\text{ext}} = -\mu_{s,z} B_{\text{ext}}.
  \]

- An electron in an atom has an additional angular momentum called its orbital angular momentum \( \vec{L}_{\text{orb}} \), with which an orbital magnetic dipole moment \( \vec{\mu}_{\text{orb}} \) is associated:
  \[
  \vec{\mu}_{\text{orb}} = -\frac{e}{2m} \vec{L}_{\text{orb}}.
  \]

- Orbital angular momentum is quantized and can have only measured values given by
  \[
  L_{\text{orb},z} = m_\ell \frac{h}{2\pi},
  \]
  \[
  \text{for } m_\ell = 0, \pm 1, \pm 2, \ldots, \pm (\text{limit}).
  \]

- The associated magnetic dipole moment is given by
  \[
  \mu_{\text{orb},z} = -m_\ell \frac{eh}{4\pi m} = -m_\ell \mu_B.
  \]

- The energy \( U \) associated with the orientation of the orbital magnetic dipole moment in an external magnetic field \( \vec{B}_{\text{ext}} \) is
  \[
  U = -\vec{\mu}_{\text{orb}} \cdot \vec{B}_{\text{ext}} = -\mu_{\text{orb},z} B_{\text{ext}}.
  \]
Magnetism and Electrons

Magnetic materials, from lodestones to tattoos, are magnetic because of the electrons within them. We have already seen one way in which electrons can generate a magnetic field: Send them through a wire as an electric current, and their motion produces a magnetic field around the wire. There are two more ways, each involving a magnetic dipole moment that produces a magnetic field in the surrounding space. However, their explanation requires quantum physics that is beyond the physics presented in this book, and so here we shall only outline the results.

Spin Magnetic Dipole Moment

An electron has an intrinsic angular momentum called its spin angular momentum (or just spin) $\vec{S}$; associated with this spin is an intrinsic spin magnetic dipole moment $\vec{\mu}_s$. (By intrinsic, we mean that $\vec{S}$ and $\vec{\mu}_s$ are basic characteristics of an electron, like its mass and electric charge.) Vectors $\vec{S}$ and $\vec{\mu}_s$ are related by

$$\vec{\mu}_s = -\frac{e}{m} \vec{S}, \quad (32-22)$$

in which $e$ is the elementary charge ($1.60 \times 10^{-19}$ C) and $m$ is the mass of an electron ($9.11 \times 10^{-31}$ kg). The minus sign means that $\vec{\mu}_s$ and $\vec{S}$ are oppositely directed.

Spin $\vec{S}$ is different from the angular momenta of Chapter 11 in two respects:

1. Spin $\vec{S}$ itself cannot be measured. However, its component along any axis can be measured.

2. A measured component of $\vec{S}$ is quantized, which is a general term that means it is restricted to certain values. A measured component of $\vec{S}$ can have only two values, which differ only in sign.

Let us assume that the component of spin $\vec{S}$ is measured along the $z$ axis of a coordinate system. Then the measured component $S_z$ can have only the two values given by

$$S_z = m_s \frac{h}{2\pi}, \quad \text{for } m_s = \pm \frac{1}{2}, \quad (32-23)$$

where $m_s$ is called the spin magnetic quantum number and $h$ ($= 6.63 \times 10^{-34}$ J·s) is the Planck constant, the ubiquitous constant of quantum physics. The signs given in Eq. 32-23 have to do with the direction of $S_z$ along the $z$ axis. When $S_z$ is parallel to the $z$ axis, $m_s$ is $+\frac{1}{2}$ and the electron is said to be spin up. When $S_z$ is antiparallel to the $z$ axis, $m_s$ is $-\frac{1}{2}$ and the electron is said to be spin down.

The spin magnetic dipole moment $\vec{\mu}_s$ of an electron also cannot be measured; only its component along any axis can be measured, and that component too is quantized, with two possible values of the same magnitude but different signs. We can relate the component $\mu_{s,z}$ measured on the $z$ axis to $S_z$ by rewriting Eq. 32-22 in component form for the $z$ axis as

$$\mu_{s,z} = -\frac{e}{m} S_z.$$

Substituting for $S_z$ from Eq. 32-23 then gives us

$$\mu_{s,z} = \pm \frac{eh}{4\pi m}, \quad (32-24)$$

where the plus and minus signs correspond to $\mu_{s,z}$ being parallel and antiparallel to the $z$ axis, respectively. The quantity on the right is the Bohr magneton $\mu_B$:

$$\mu_B = \frac{eh}{4\pi m} = 9.27 \times 10^{-24} \text{ J/T} \quad \text{(Bohr magneton).} \quad (32-25)$$
Spin magnetic dipole moments of electrons and other elementary particles can be expressed in terms of $\mu_B$. For an electron, the magnitude of the measured $z$ component of $\vec{\mu}$ is

$$|\mu_{z,e}| = 1 \mu_B.$$  \hspace{1cm} (32-26)

(The quantum physics of the electron, called quantum electrodynamics, or QED, reveals that $\mu_{z,e}$ is actually slightly greater than $1 \mu_B$, but we shall neglect that fact.)

**Energy.** When an electron is placed in an external magnetic field $\vec{B}_{ext}$, an energy $U$ can be associated with the orientation of the electron’s spin magnetic dipole moment $\vec{\mu}$ just as an energy can be associated with the orientation of the magnetic dipole moment $\vec{\mu}$ of a current loop placed in $\vec{B}_{ext}$. From Eq. 28-38, the orientation energy for the electron is

$$U = -\vec{\mu} \cdot \vec{B}_{ext} = -\mu_{z,e} B_{ext},$$  \hspace{1cm} (32-27)

where the $z$ axis is taken to be in the direction of $\vec{B}_{ext}$.

If we imagine an electron to be a microscopic sphere (which it is not), we can represent the spin $\vec{S}$, the spin magnetic dipole moment $\vec{\mu}_s$, and the associated magnetic dipole field as in Fig. 32-10. Although we use the word “spin” here, electrons do not spin like tops. How, then, can something have angular momentum without actually rotating? Again, we would need quantum physics to provide the answer.

Protons and neutrons also have an intrinsic angular momentum called spin and an associated intrinsic spin magnetic dipole moment. For a proton those two vectors have the same direction, and for a neutron they have opposite directions. We shall not examine the contributions of these dipole moments to the magnetic fields of atoms because they are about a thousand times smaller than that due to an electron.

**Checkpoint 4**

The figure here shows the spin orientations of two particles in an external magnetic field $\vec{B}_{ext}$. (a) If the particles are electrons, which spin orientation is at lower energy? (b) If, instead, the particles are protons, which spin orientation is at lower energy?

**Orbital Magnetic Dipole Moment**

When it is in an atom, an electron has an additional angular momentum called its orbital angular momentum $\vec{L}_{orb}$. Associated with $\vec{L}_{orb}$ is an orbital magnetic dipole moment $\vec{\mu}_{orb}$; the two are related by

$$\vec{\mu}_{orb} = -\frac{e}{2m} \vec{L}_{orb},$$  \hspace{1cm} (32-28)

The minus sign means that $\vec{\mu}_{orb}$ and $\vec{L}_{orb}$ have opposite directions.

Orbital angular momentum $\vec{L}_{orb}$ cannot be measured; only its component along any axis can be measured, and that component is quantized. The component along, say, a $z$ axis can have only the values given by

$$L_{orb,z} = m_\ell \frac{\hbar}{2\pi}, \quad \text{for } m_\ell = 0, \pm 1, \pm 2, \ldots, \pm (\text{limit}),$$  \hspace{1cm} (32-29)

in which $m_\ell$ is called the orbital magnetic quantum number and “limit” refers to some largest allowed integer value for $m_\ell$. The signs in Eq. 32-29 have to do with the direction of $L_{orb,z}$ along the $z$ axis.
The orbital magnetic dipole moment $\vec{\mu}_{\text{orb}}$ of an electron also cannot itself be measured; only its component along an axis can be measured, and that component is quantized. By writing Eq. 32-28 for a component along the same $z$ axis as above and then substituting for $L_{\text{orb},z}$ from Eq. 32-29, we can write the $z$ component $\mu_{\text{orb},z}$ of the orbital magnetic dipole moment as

$$\mu_{\text{orb},z} = -m_e e h \frac{e}{4\pi m}.$$  

and, in terms of the Bohr magneton, as

$$\mu_{\text{orb},z} = -m_e \mu_B.$$  

When an atom is placed in an external magnetic field $\vec{B}_{\text{ext}}$, an energy $U$ can be associated with the orientation of the orbital magnetic dipole moment of each electron in the atom. Its value is

$$U = -\vec{\mu}_{\text{orb}} \cdot \vec{B}_{\text{ext}} = -\mu_{\text{orb},z} B_{\text{ext}}.$$  

where the $z$ axis is taken in the direction of $\vec{B}_{\text{ext}}$.

Although we have used the words “orbit” and “orbital” here, electrons do not orbit the nucleus of an atom like planets orbiting the Sun. How can an electron have an orbital angular momentum without orbiting in the common meaning of the term? Once again, this can be explained only with quantum physics.

**Loop Model for Electron Orbits**

We can obtain Eq. 32-28 with the nonquantum derivation that follows, in which we assume that an electron moves along a circular path with a radius that is much larger than an atomic radius (hence the name “loop model”). However, the derivation does not apply to an electron within an atom (for which we need quantum physics).

We imagine an electron moving at constant speed $v$ in a circular path of radius $r$, counterclockwise as shown in Fig. 32-11. The motion of the negative charge of the electron is equivalent to a conventional current $i$ (of positive charge) that is clockwise, as also shown in Fig. 32-11. The magnitude of the orbital magnetic dipole moment of such a current loop is obtained from Eq. 28-35 with $N = 1$:

$$\mu_{\text{orb}} = iA,$$  

where $A$ is the area enclosed by the loop. The direction of this magnetic dipole moment is, from the right-hand rule of Fig. 29-21, downward in Fig. 32-11.

To evaluate Eq. 32-33, we need the current $i$. Current is, generally, the rate at which charge passes some point in a circuit. Here, the charge of magnitude $e$ takes a time $T = 2\pi r/v$ to circle from any point back through that point, so

$$i = \frac{\text{charge}}{\text{time}} = \frac{e}{2\pi r/v}.$$  

Substituting this and the area $A = \pi r^2$ of the loop into Eq. 32-33 gives us

$$\mu_{\text{orb}} = \frac{e}{2\pi r/v} \pi r^2 = \frac{e vr}{2}.$$  

To find the electron’s orbital angular momentum $\vec{L}_{\text{orb}}$, we use Eq. 11-18, $\vec{L} = m(\vec{r} \times \vec{v})$. Because $\vec{r}$ and $\vec{v}$ are perpendicular, $\vec{L}_{\text{orb}}$ has the magnitude

$$L_{\text{orb}} = mr v \sin 90^\circ = mr v.$$  

The vector $\vec{L}_{\text{orb}}$ is directed upward in Fig. 32-11 (see Fig. 11-12). Combining
Eqs. 32-35 and 32-36, generalizing to a vector formulation, and indicating the opposite directions of the vectors with a minus sign yield

$$\vec{\mu}_{\text{orb}} = -\frac{e}{2m} \vec{I}_{\text{orb}}$$

which is Eq. 32-28. Thus, by “classical” (nonquantum) analysis we have obtained the same result, in both magnitude and direction, given by quantum physics. You might wonder, seeing as this derivation gives the correct result for an electron within an atom, why the derivation is invalid for that situation. The answer is that this line of reasoning yields other results that are contradicted by experiments.

**Loop Model in a Nonuniform Field**

We continue to consider an electron orbit as a current loop, as we did in Fig. 32-11. Now, however, we draw the loop in a nonuniform magnetic field $\vec{B}_{\text{ext}}$ as shown in Fig. 32-12a. (This field could be the diverging field near the north pole of the magnet in Fig. 32-4.) We make this change to prepare for the next several modules, in which we shall discuss the forces that act on magnetic materials when the materials are placed in a nonuniform magnetic field. We shall discuss these forces by assuming that the electron orbits in the materials are tiny current loops like that in Fig. 32-12a.

Here we assume that the magnetic field vectors all around the electron’s circular path have the same magnitude and form the same angle with the vertical, as shown in Figs. 32-12b and d. We also assume that all the electrons in an atom move either counterclockwise (Fig. 32-12b) or clockwise (Fig. 32-12d). The associated conventional current $i$ around the current loop and the orbital magnetic dipole moment $\vec{\mu}_{\text{orb}}$ produced by $i$ are shown for each direction of motion.

Figures 32-12c and e show diametrically opposite views of a length element $d\vec{L}$ of the loop that has the same direction as $i$, as seen from the plane of the orbit. Also shown are the field $\vec{B}_{\text{ext}}$ and the resulting magnetic force $d\vec{F}$ on $d\vec{L}$. Recall that a current along an element $d\vec{L}$ in a magnetic field $\vec{B}_{\text{ext}}$ experiences a magnetic force $d\vec{F}$ as given by Eq. 28-28:

$$d\vec{F} = i d\vec{L} \times \vec{B}_{\text{ext}}.$$  \hspace{1cm} (32-37)

On the left side of Fig. 32-12c, Eq. 32-37 tells us that the force $d\vec{F}$ is directed upward and rightward. On the right side, the force $d\vec{F}$ is just as large and is directed upward and leftward. Because their angles are the same, the horizontal components of these two forces cancel and the vertical components add. The same is true at any other two symmetric points on the loop. Thus, the net force on the current loop of Fig. 32-12b must be upward. The same reasoning leads to a downward net force on the loop in Fig. 32-12d. We shall use these two results shortly when we examine the behavior of magnetic materials in nonuniform magnetic fields.

**Magnetic Materials**

Each electron in an atom has an orbital magnetic dipole moment and a spin magnetic dipole moment that combine vectorially. The resultant of these two vector quantities combines vectorially with similar resultants for all other electrons in the atom, and the resultant for each atom combines with those for all other atoms in a sample of a material. If the combination of all these magnetic dipole moments produces a magnetic field, then the material is magnetic. There are three general types of magnetism: diamagnetism, paramagnetism, and ferromagnetism.
1. **Diamagnetism** is exhibited by all common materials but is so feeble that it is masked if the material also exhibits magnetism of either of the other two types. In diamagnetism, weak magnetic dipole moments are produced in the atoms of the material when the material is placed in an external magnetic field $\vec{B}_{\text{ext}}$; the combination of all those induced dipole moments gives the material as a whole only a feeble net magnetic field. The dipole moments and thus their net field disappear when $\vec{B}_{\text{ext}}$ is removed. The term *diamagnetic material* usually refers to materials that exhibit only diamagnetism.

2. **Paramagnetism** is exhibited by materials containing transition elements, rare earth elements, and actinide elements (see Appendix G). Each atom of such a material has a permanent resultant magnetic dipole moment, but the moments are randomly oriented in the material and the material as a whole lacks a net magnetic field. However, an external magnetic field $\vec{B}_{\text{ext}}$ can partially align the atomic magnetic dipole moments to give the material a net magnetic field. The alignment and thus its field disappear when $\vec{B}_{\text{ext}}$ is removed. The term *paramagnetic material* usually refers to materials that exhibit primarily paramagnetism.

3. **Ferromagnetism** is a property of iron, nickel, and certain other elements (and of compounds and alloys of these elements). Some of the electrons in these materials have their resultant magnetic dipole moments aligned, which produces regions with strong magnetic dipole moments. An external field $\vec{B}_{\text{ext}}$ can then align the magnetic moments of such regions, producing a strong magnetic field for a sample of the material; the field partially persists when $\vec{B}_{\text{ext}}$ is removed. We usually use the terms *ferromagnetic material* and *magnetic material* to refer to materials that exhibit primarily ferromagnetism.

The next three modules explore these three types of magnetism.

### 32-6 DIAMAGNETISM

**Learning Objectives**

*After reading this module, you should be able to . . .*

32.36 For a diamagnetic sample placed in an external magnetic field, identify that the field produces a magnetic dipole moment in the sample, and identify the relative orientations of that moment and the field.

32.37 For a diamagnetic sample in a nonuniform magnetic field, describe the force on the sample and the resulting motion.

**Key Ideas**

- Diamagnetic materials exhibit magnetism only when placed in an external magnetic field; there they form magnetic dipoles directed opposite the external field.
- In a nonuniform field, diamagnetic materials are repelled from the region of greater magnetic field.

**Diamagnetism**

We cannot yet discuss the quantum physical explanation of diamagnetism, but we can provide a classical explanation with the loop model of Figs. 32-11 and 32-12. To begin, we assume that in an atom of a diamagnetic material each electron can orbit only clockwise as in Fig. 32-12d or counterclockwise as in Fig. 32-12b. To account for the lack of magnetism in the absence of an external magnetic field $\vec{B}_{\text{ext}}$, we assume the atom lacks a net magnetic dipole moment. This implies that before $\vec{B}_{\text{ext}}$ is applied, the number of electrons orbiting in one direction is the same as that orbiting in the opposite direction, with the result that the net upward magnetic dipole moment of the atom equals the net downward magnetic dipole moment.
Now let’s turn on the nonuniform field $\vec{B}_{\text{ext}}$ of Fig. 32-12a, in which $\vec{B}_{\text{ext}}$ is directed upward but is diverging (the magnetic field lines are diverging). We could do this by increasing the current through an electromagnet or by moving the north pole of a bar magnet closer to, and below, the orbits. As the magnitude of $\vec{B}_{\text{ext}}$ increases from zero to its final maximum, steady-state value, a clockwise electric field is induced around each electron’s orbital loop according to Faraday’s law and Lenz’s law. Let us see how this induced electric field affects the orbiting electrons in Figs. 32-12b and d.

In Fig. 32-12b, the counterclockwise electron is accelerated by the clockwise electric field. Thus, as the magnetic field increases to its maximum value, the electron speed increases to a maximum value. This means that the associated conventional current $i$ and the downward magnetic dipole moment due to $i$ also increase.

In Fig. 32-12d, the clockwise electron is decelerated by the clockwise electric field. Thus, here, the electron speed, the associated current $i$, and the upward magnetic dipole moment due to $i$ all decrease. By turning on field $\vec{B}_{\text{ext}}$, we have given the atom a net magnetic dipole moment that is downward. This would also be so if the magnetic field were uniform.

**Force.** The nonuniformity of field $\vec{B}_{\text{ext}}$ also affects the atom. Because the current $i$ in Fig. 32-12b increases, the upward magnetic forces $d\vec{F}$ in Fig. 32-12c also increase, as does the net upward force on the current loop. Because current $i$ in Fig. 32-12d decreases, the downward magnetic forces $d\vec{F}$ in Fig. 32-12e also decrease, as does the net downward force on the current loop. Thus, by turning on the nonuniform field $\vec{B}_{\text{ext}}$, we have produced a net force on the atom; moreover, that force is directed away from the region of greater magnetic field.

We have argued with fictitious electron orbits (current loops), but we have ended up with exactly what happens to a diamagnetic material: If we apply the magnetic field of Fig. 32-12, the material develops a downward magnetic dipole moment and experiences an upward force. When the field is removed, both the dipole moment and the force disappear. The external field need not be positioned as shown in Fig. 32-12; similar arguments can be made for other orientations of $\vec{B}_{\text{ext}}$. In general,

A diamagnetic material placed in an external magnetic field $\vec{B}_{\text{ext}}$ develops a magnetic dipole moment directed opposite $\vec{B}_{\text{ext}}$. If the field is nonuniform, the diamagnetic material is repelled from a region of greater magnetic field toward a region of lesser field.

The frog in Fig. 32-13 is diamagnetic (as is any other animal). When the frog was placed in the diverging magnetic field near the top end of a vertical current-carrying solenoid, every atom in the frog was repelled upward, away from the region of stronger magnetic field at that end of the solenoid. The frog moved upward into weaker and weaker magnetic field until the upward magnetic force balanced the gravitational force on it, and there it hung in midair. The frog is not in discomfort because every atom is subject to the same forces and thus there is no force variation within the frog. The sensation is similar to the “weightless” situation of floating in water, which frogs like very much. If we went to the expense of building a much larger solenoid, we could similarly levitate a person in midair due to the person’s diamagnetism.

**Checkpoint 5**

The figure shows two diamagnetic spheres located near the south pole of a bar magnet. Are (a) the magnetic forces on the spheres and (b) the magnetic dipole moments of the spheres directed toward or away from the bar magnet? (c) Is the magnetic force on sphere 1 greater than, less than, or equal to that on sphere 2?
32-7  PARAMAGNETISM

Learning Objectives

After reading this module, you should be able to . . .

32.38  For a paramagnetic sample placed in an external magnetic field, identify the relative orientations of the field and the sample’s magnetic dipole moment.

32.39  For a paramagnetic sample in a nonuniform magnetic field, describe the force on the sample and the resulting motion.

32.40  Apply the relationship between a sample’s magnetization $M$, its measured magnetic moment, and its volume.

32.41  Apply Curie’s law to relate a sample’s magnetization $M$ to its temperature $T$, its Curie constant $C$, and the magnitude $B$ of the external field.

32.42  Given a magnetization curve for a paramagnetic sample, relate the extent of the magnetization for a given magnetic field and temperature.

32.43  For a paramagnetic sample at a given temperature and in a given magnetic field, compare the energy associated with the dipole orientations and the thermal motion.

Key Ideas

- Paramagnetic materials have atoms with a permanent magnetic dipole moment but the moments are randomly oriented, with no net moment, unless the material is in an external magnetic field, where the dipoles tend to align with that field.
- The extent of alignment within a volume $V$ is measured as the magnetization $M$, given by

$$M = \frac{\text{measured magnetic moment}}{V}.$$

- Complete alignment (saturation) of all $N$ dipoles in the volume gives a maximum value $M_{\text{max}} = N\mu/V$.
- At low values of the ratio $B_{\text{ext}}/T$,

$$M = C \frac{B_{\text{ext}}}{T} \quad \text{(Curie’s law)},$$

where $T$ is the temperature (in kelvins) and $C$ is a material’s Curie constant.
- In a nonuniform external field, a paramagnetic material is attracted to the region of greater magnetic field.

Paramagnetism

In paramagnetic materials, the spin and orbital magnetic dipole moments of the electrons in each atom do not cancel but add vectorially to give the atom a net (and permanent) magnetic dipole moment $\mu$. In the absence of an external magnetic field, these atomic dipole moments are randomly oriented, and the net magnetic dipole moment of the material is zero. However, if a sample of the material is placed in an external magnetic field $B_{\text{ext}}$, the magnetic dipole moments tend to line up with the field, which gives the sample a net magnetic dipole moment. This alignment with the external field is the opposite of what we saw with diamagnetic materials.

A paramagnetic material placed in an external magnetic field $B_{\text{ext}}$ develops a magnetic dipole moment in the direction of $B_{\text{ext}}$. If the field is nonuniform, the paramagnetic material is attracted toward a region of greater magnetic field from a region of lesser field.

A paramagnetic sample with $N$ atoms would have a magnetic dipole moment of magnitude $N\mu$ if alignment of its atomic dipoles were complete. However, random collisions of atoms due to their thermal agitation transfer energy among the atoms, disrupting their alignment and thus reducing the sample’s magnetic dipole moment.

**Thermal Agitation.** The importance of thermal agitation may be measured by comparing two energies. One, given by Eq. 19-24, is the mean translational kinetic energy $K (= \frac{1}{2}kT)$ of an atom at temperature $T$, where $k$ is the Boltzmann constant ($1.38 \times 10^{-23}$ J/K) and $T$ is in kelvins (not Celsius degrees). The other,
derived from Eq. 28-38, is the difference in energy \( \Delta U_B \) between parallel alignment and antiparallel alignment of the magnetic dipole moment of an atom and the external field. (The lower energy state is \(-\mu B_{ext}\) and the higher energy state is \(+\mu B_{ext}\).) As we shall show below, \( K \gg \Delta U_B \), even for ordinary temperatures and field magnitudes. Thus, energy transfers during collisions among atoms can significantly disrupt the alignment of the atomic dipole moments, keeping the magnetic dipole moment of a sample much less than \( N \mu \).

**Magnetization.** We can express the extent to which a given paramagnetic sample is magnetized by finding the ratio of its magnetic dipole moment to its volume \( V \). This vector quantity, the magnetic dipole moment per unit volume, is the magnetization \( \vec{M} \) of the sample, and its magnitude is

\[
M = \frac{\text{measured magnetic moment}}{V}.
\]

The unit of \( \vec{M} \) is the ampere–square meter per cubic meter, or ampere per meter (A/m). Complete alignment of the atomic dipole moments, called saturation of the sample, corresponds to the maximum value \( M_{\text{max}} = N \mu / V \).

In 1895 Pierre Curie discovered experimentally that the magnetization of a paramagnetic sample is directly proportional to the magnitude of the external magnetic field \( B_{\text{ext}} \) and inversely proportional to the temperature \( T \) in kelvins:

\[
M = C \frac{B_{\text{ext}}}{T}.
\]

Equation 32-39 is known as Curie’s law, and \( C \) is called the Curie constant. Curie’s law is reasonable in that increasing \( B_{\text{ext}} \) tends to align the atomic dipole moments in a sample and thus to increase \( M \), whereas increasing \( T \) tends to disrupt the alignment via thermal agitation and thus to decrease \( M \). However, the law is actually an approximation that is valid only when the ratio \( B_{\text{ext}} / T \) is not too large.

Figure 32-14 shows the ratio \( M / M_{\text{max}} \) as a function of \( B_{\text{ext}} / T \) for a sample of the salt potassium chromium sulfate, in which chromium ions are the paramagnetic substance. The plot is called a magnetization curve. The straight line for Curie’s law fits the experimental data at the left, for \( B_{\text{ext}} / T \) below about 0.5 T/K. The curve that fits all the data points is based on quantum physics. The data on the right side, near saturation, are very difficult to obtain because they require very strong magnetic fields (about 100 000 times Earth’s field), even at very low temperatures.

**Checkpoint 6**

The figure here shows two paramagnetic spheres located near the south pole of a bar magnet. Are (a) the magnetic forces on the spheres and (b) the magnetic dipole moments of the spheres directed toward or away from the bar magnet? (c) Is the magnetic force on sphere 1 greater than, less than, or equal to that on sphere 2?
Ferromagnetism

When we speak of magnetism in everyday conversation, we almost always have a mental picture of a bar magnet or a disk magnet (probably clinging to a refrigerator door). That is, we picture a ferromagnetic material having strong, 

Sample Problem 32.03 Orientation energy of a paramagnetic gas in a magnetic field

A paramagnetic gas at room temperature \((T = 300 \text{ K})\) is placed in an external uniform magnetic field of magnitude \(B = 1.5 \text{ T}\); the atoms of the gas have magnetic dipole moment \(\mu = 1.0 \mu_B\). Calculate the mean translational kinetic energy \(K\) of an atom of the gas and the energy difference \(\Delta U_B\) between parallel alignment \((\theta = 0^\circ)\) and antiparallel alignment \((\theta = 180^\circ)\) as

\[
\Delta U_B = -\mu B \cos 180^\circ - (-\mu B \cos 0^\circ) = 2\mu B
\]

\[
= 2\mu_B B = 2(9.27 \times 10^{-24} \text{ J/T})(1.5 \text{ T})
\]

\[
= 2.8 \times 10^{-21} \text{ J} = 0.00017 \text{ eV.} \quad \text{(Answer)}
\]

Here \(K\) is about 230 times \(\Delta U_B\); so energy exchanges among the atoms during their collisions with one another can easily reorient any magnetic dipole moments that might be aligned with the external magnetic field. That is, as soon as a magnetic dipole moment happens to become aligned with the external field, in the dipole’s low energy state, chances are very good that a neighboring atom will hit the atom, transferring enough energy to put the dipole in a higher energy state. Thus, the magnetic dipole moment exhibited by the paramagnetic gas must be due to fleeting partial alignments of the atomic dipole moments.

32-8 FERROMAGNETISM

Learning Objectives

After reading this module, you should be able to . . .

32.44 Identify that ferromagnetism is due to a quantum mechanical interaction called exchange coupling.
32.45 Explain why ferromagnetism disappears when the temperature exceeds the material’s Curie temperature.
32.46 Apply the relationship between the magnetization of a ferromagnetic sample and the magnetic moment of its atoms.
32.47 For a ferromagnetic sample at a given temperature and in a given magnetic field, compare the energy associated with the dipole orientations and the thermal motion.
32.48 Describe and sketch a Rowland ring.
32.49 Identify magnetic domains.
32.50 For a ferromagnetic sample placed in an external magnetic field, identify the relative orientations of the field and the magnetic dipole moment.
32.51 Identify the motion of a ferromagnetic sample in a nonuniform field.
32.52 For a ferromagnetic object placed in a uniform magnetic field, calculate the torque and orientation energy.
32.53 Explain hysteresis and a hysteresis loop.
32.54 Identify the origin of lodestones.

Key Ideas

- The magnetic dipole moments in a ferromagnetic material can be aligned by an external magnetic field and then, after the external field is removed, remain partially aligned in regions (domains).
- Alignment is eliminated at temperatures above a material’s Curie temperature.
- In a nonuniform external field, a ferromagnetic material is attracted to the region of greater magnetic field.

Ferromagnetism

When we speak of magnetism in everyday conversation, we almost always have a mental picture of a bar magnet or a disk magnet (probably clinging to a refrigerator door). That is, we picture a ferromagnetic material having strong,
permanent magnetism, and not a diamagnetic or paramagnetic material having weak, temporary magnetism.

Iron, cobalt, nickel, gadolinium, dysprosium, and alloys containing these elements exhibit ferromagnetism because of a quantum physical effect called exchange coupling in which the electron spins of one atom interact with those of neighboring atoms. The result is alignment of the magnetic dipole moments of the atoms, in spite of the randomizing tendency of atomic collisions due to thermal agitation. This persistent alignment is what gives ferromagnetic materials their permanent magnetism.

**Thermal Agitation.** If the temperature of a ferromagnetic material is raised above a certain critical value, called the Curie temperature, the exchange coupling ceases to be effective. Most such materials then become simply paramagnetic; that is, the dipoles still tend to align with an external field but much more weakly, and thermal agitation can now more easily disrupt the alignment. The Curie temperature for iron is 1043 K (\(= 770^\circ C\)).

**Measurement.** The magnetization of a ferromagnetic material such as iron can be studied with an arrangement called a Rowland ring (Fig. 32-15). The material is formed into a thin toroidal core of circular cross section. A primary coil \(P\) having \(n\) turns per unit length is wrapped around the core and carries current \(i_p\). (The coil is essentially a long solenoid bent into a circle.) If the iron core were not present, the magnitude of the magnetic field inside the coil would be, from Eq. 29-23,

\[
B_0 = \mu_0 i_p n. \tag{32-40}
\]

However, with the iron core present, the magnetic field \(B\) inside the coil is greater than \(B_0\), usually by a large amount. We can write the magnitude of this field as

\[
B = B_0 + B_M, \tag{32-41}
\]

where \(B_M\) is the magnitude of the magnetic field contributed by the iron core. This contribution results from the alignment of the atomic dipole moments within the iron, due to exchange coupling and to the applied magnetic field \(B_0\), and is proportional to the magnetization \(M\) of the iron. That is, the contribution \(B_M\) is proportional to the magnetic dipole moment per unit volume of the iron. To determine \(B_M\) we use a secondary coil \(S\) to measure \(B\), compute \(B_0\) with Eq. 32-40, and subtract as suggested by Eq. 32-41.

Figure 32-16 shows a magnetization curve for a ferromagnetic material in a Rowland ring: The ratio \(B_M/B_{M,max}\) where \(B_{M,max}\) is the maximum possible value of \(B_M\), corresponding to saturation, is plotted versus \(B_0\). The curve is like Fig. 32-14, the magnetization curve for a paramagnetic substance: Both curves show the extent to which an applied magnetic field can align the atomic dipole moments of a material.

For the ferromagnetic core yielding Fig. 32-16, the alignment of the dipole moments is about 70% complete for \(B_0 \approx 1 \times 10^{-3} \, T\). If \(B_0\) were increased to 1 T, the alignment would be almost complete (but \(B_0 = 1 \, T\), and thus almost complete saturation, is quite difficult to obtain).

**Magnetic Domains**

Exchange coupling produces strong alignment of adjacent atomic dipoles in a ferromagnetic material at a temperature below the Curie temperature. Why, then, isn’t the material naturally at saturation even when there is no applied magnetic field \(B_0\)? Why isn’t every piece of iron a naturally strong magnet?

To understand this, consider a specimen of a ferromagnetic material such as iron that is in the form of a single crystal; that is, the arrangement of the atoms that make it up—its crystal lattice—extends with unbroken regularity throughout the volume of the specimen. Such a crystal will, in its normal state, be made up of a number of magnetic domains. These are regions of the crystal throughout which the alignment of the atomic dipoles is essentially perfect. The domains,
however, are not all aligned. For the crystal as a whole, the domains are so oriented that they largely cancel with one another as far as their external magnetic effects are concerned.

Figure 32-17 is a magnified photograph of such an assembly of domains in a single crystal of nickel. It was made by sprinkling a colloidal suspension of finely powdered iron oxide on the surface of the crystal. The domain boundaries, which are thin regions in which the alignment of the elementary dipoles changes from a certain orientation in one of the domains forming the boundary to a different orientation in the other domain, are the sites of intense, but highly localized and nonuniform, magnetic fields. The suspended colloidal particles are attracted to these boundaries and show up as the white lines (not all the domain boundaries are apparent in Fig. 32-17). Although the atomic dipoles in each domain are completely aligned as shown by the arrows, the crystal as a whole may have only a very small resultant magnetic moment.

Actually, a piece of iron as we ordinarily find it is not a single crystal but an assembly of many tiny crystals, randomly arranged; we call it a polycrystalline solid. Each tiny crystal, however, has its array of variously oriented domains, just as in Fig. 32-17. If we magnetize such a specimen by placing it in an external magnetic field of gradually increasing strength, we produce two effects; together they produce a magnetization curve of the shape shown in Fig. 32-16. One effect is a growth in size of the domains that are oriented along the external field at the expense of those that are not. The second effect is a shift of the orientation of the dipoles within a domain, as a unit, to become closer to the field direction.

Exchange coupling and domain shifting give us the following result:

A ferromagnetic material placed in an external magnetic field $\vec{B}_0$ develops a strong magnetic dipole moment in the direction of $\vec{B}_0$. If the field is nonuniform, the ferromagnetic material is attracted toward a region of greater magnetic field from a region of lesser field.

**Hysteresis**

Magnetization curves for ferromagnetic materials are not retraced as we increase and then decrease the external magnetic field $B_0$. Figure 32-18 is a plot of $B_M$ versus $B_0$ during the following operations with a Rowland ring: (1) Starting with the iron unmagnetized (point a), increase the current in the toroid until $B_0 = \mu_0 M$ has the value corresponding to point b; (2) reduce the current in the toroid winding (and thus $B_0$) back to zero (point c); (3) reverse the toroid current and increase it in magnitude until $B_0$ has the value corresponding to point d; (4) reduce the current to zero again (point e); (5) reverse the current once more until point b is reached again.

The lack of retraceability shown in Fig. 32-18 is called hysteresis, and the curve bcdeb is called a hysteresis loop. Note that at points c and e the iron core is magnetized, even though there is no current in the toroid windings; this is the familiar phenomenon of permanent magnetism.

Hysteresis can be understood through the concept of magnetic domains. Evidently the motions of the domain boundaries and the reorientations of the domain directions are not totally reversible. When the applied magnetic field $B_0$ is increased and then decreased back to its initial value, the domains do not return completely to their original configuration but retain some “memory” of their alignment after the initial increase. This memory of magnetic materials is essential for the magnetic storage of information.

This memory of the alignment of domains can also occur naturally. When lightning sends currents along multiple tortuous paths through the ground, the currents produce intense magnetic fields that can suddenly magnetize any
Sample Problem 32.04  Magnetic dipole moment of a compass needle

A compass needle made of pure iron (density 7900 kg/m³) has a length $L$ of 3.0 cm, a width of 1.0 mm, and a thickness of 0.50 mm. The magnitude of the magnetic dipole moment of an iron atom is $\mu_{Fe} = 2.1 \times 10^{-23}$ J/T. If the magnetization of the needle is equivalent to the alignment of 10% of the atoms in the needle, what is the magnitude of the needle’s magnetic dipole moment $\vec{\mu}$?

Next, we can rewrite Eq. 32-43 in terms of the needle’s mass $m$, the molar mass $M$, and Avogadro’s number $N_A$:

$$N = \frac{mN_A}{M} \quad (32-45)$$

The needle’s mass $m$ is the product of its density and its volume. The volume works out to be $1.5 \times 10^{-8}$ m³; so

$$m = (7900 \text{ kg/m}^3)(1.5 \times 10^{-8} \text{ m}^3) = 1.185 \times 10^{-4} \text{ kg.}$$

Substituting into Eq. 32-45 with this value for $m$, and also 55.847 g/mol (= 0.055 847 kg/mol) for $M$ and $6.02 \times 10^{23}$ for $N_A$, we find

$$N = \frac{(1.185 \times 10^{-4} \text{ kg})(6.02 \times 10^{23})}{0.055 847 \text{ kg/mol}} = 1.2774 \times 10^{21}.$$

Finding $\mu$: Substituting our value of $N$ and the value of $\mu_{Fe}$ into Eq. 32-42 then yields

$$\mu = (0.10)(1.2774 \times 10^{21})(2.1 \times 10^{-23} \text{ J/T})$$

$$= 2.682 \times 10^{-3} \text{ J/T} = 2.7 \times 10^{-3} \text{ J/T.} \quad (Answer)$$
loop. The idea of a displacement current allows us to retain the notion of continuity of current through a capacitor. However, displacement current is not a transfer of charge.

Maxwell’s Equations Maxwell’s equations, displayed in Table 32-1, summarize electromagnetism and form its foundation, including optics.

Earth’s Magnetic Field Earth’s magnetic field can be approximated as being that of a magnetic dipole whose dipole moment makes an angle of 11.5° with Earth’s rotation axis, and with the south pole of the dipole in the Northern Hemisphere. The direction of the local magnetic field at any point on Earth’s surface is given by the field declination (the angle left or right from geographic north) and the field inclination (the angle up or down from the horizontal).

Spin Magnetic Dipole Moment An electron has an intrinsic angular momentum called spin angular momentum (or spin) \( \vec{S} \), with which an intrinsic spin magnetic dipole moment \( \vec{\mu}_s \) is associated:

\[
\vec{\mu}_s = -\frac{e}{m} \vec{S}. \tag{32-22}
\]

For a measurement along a \( z \) axis, the component \( S_z \) can have only the values given by

\[
S_z = m_s \frac{h}{2\pi}, \quad \text{for } m_s = \pm \frac{1}{2}. \tag{32-23}
\]

where \( h = 6.63 \times 10^{-34} \text{ J} \cdot \text{s} \) is the Planck constant. Similarly,

\[
\mu_{sz} = \pm \frac{e}{4\pi m} \frac{h}{2\pi} = \pm \mu_B, \tag{32-24, 32-26}
\]

where \( \mu_B \) is the Bohr magneton:

\[
\mu_B = \frac{e}{4\pi m} \frac{h}{2\pi} = 9.27 \times 10^{-24} \text{ J/T}. \tag{32-25}
\]

The energy \( U \) associated with the orientation of the spin magnetic dipole moment in an external magnetic field \( \vec{B}_{ext} \) is

\[
U = -\vec{\mu}_s \cdot \vec{B}_{ext} = -\mu_{sz} B_{ext}. \tag{32-27}
\]

Orbital Magnetic Dipole Moment An electron in an atom has an additional angular momentum called its orbital angular momentum \( \vec{L}_{orb} \), with which an orbital magnetic dipole moment \( \vec{\mu}_{orb} \) is associated:

\[
\vec{\mu}_{orb} = -\frac{e}{2m} \vec{L}_{orb}. \tag{32-28}
\]

Orbital angular momentum is quantized and can have only measured values given by

\[
L_{orb,z} = m_L \frac{h}{2\pi}, \quad \text{for } m_L = 0, \pm 1, \pm 2, \ldots, \pm (\text{limit}). \tag{32-29}
\]

The associated magnetic dipole moment is given by

\[
\mu_{orb,z} = -m_L \frac{e}{4\pi m} \frac{h}{2\pi} = -m_L \mu_B. \tag{32-30, 32-31}
\]

The energy \( U \) associated with the orbital orientation of the magnetic dipole moment in an external magnetic field \( \vec{B}_{ext} \) is

\[
U = -\vec{\mu}_{orb} \cdot \vec{B}_{ext} = -\mu_{orb,z} B_{ext}. \tag{32-32}
\]

Diamagnetism Diamagnetic materials exhibit magnetism only when placed in an external magnetic field; there they form magnetic dipoles directed opposite the external field. In a nonuniform field, they are repelled from the region of greater magnetic field.

Paramagnetism Paramagnetic materials have atoms with a permanent magnetic dipole moment but the moments are randomly oriented unless the material is in an external magnetic field \( \vec{B}_{ext} \), where the dipoles tend to align with the external field. The extent of alignment within a volume \( V \) is measured as the magnetization \( M \), given by

\[
M = \frac{\text{measured magnetic moment}}{V}. \tag{32-38}
\]

Complete alignment (saturation) of all \( N \) dipoles in the volume gives a maximum value \( M_{\text{max}} = N \mu/V \). At low values of the ratio \( B_{ext}/T \),

\[
M = C \frac{B_{ext}}{T} \quad \text{(Curie’s law)}, \tag{32-39}
\]

where \( T \) is the temperature (kelvins) and \( C \) is a material’s Curie constant.

In a nonuniform external field, a paramagnetic material is attracted to the region of greater magnetic field.

Ferromagnetism The magnetic dipole moments in a ferromagnetic material can be aligned by an external magnetic field and then, after the external field is removed, remain partially aligned in regions (domains). Alignment is eliminated at temperatures above a material’s Curie temperature. In a nonuniform external field, a ferromagnetic material is attracted to the region of greater magnetic field.

Questions

1. Figure 32-19a shows a capacitor, with circular plates, that is being charged. Point \( a \) (near one of the connecting wires) and point \( b \) (inside the capacitor gap) are equidistant from the central axis, as are point \( c \) (not so near the wire) and point \( d \) (between the plates but outside the gap). In Fig. 32-19b, one curve gives the variation with distance \( r \) of the magnitude of the magnetic field inside and outside the wire. The other curve gives the variation with distance \( r \) of the magnitude of the magnetic field inside and outside the gap. The two curves partially overlap. Which of the three points on the curves correspond to which of the four points of Fig. 32-19a?
Figure 32-20 shows a parallel-plate capacitor and the current in the connecting wires that is discharging the capacitor. Are the directions of (a) electric field $E$ and (b) displacement current $i_d$ leftward or rightward between the plates? (c) Is the magnetic field at point $P$ into or out of the page?

Figure 32-21 shows, in two situations, an electric field vector $\vec{E}$ and an induced magnetic field line. In each, is the magnitude of $E$ increasing or decreasing?

Figure 32-22a shows a pair of opposite spin orientations for an electron in an external magnetic field $\vec{B}_{\text{ext}}$. Figure 32-22b gives three choices for the graph of the energies associated with those orientations as a function of the magnitude of $\vec{B}_{\text{ext}}$. Choices $b$ and $c$ consist of intersecting lines, choice $a$ of parallel lines. Which is the correct choice?

An electron in an external magnetic field $\vec{B}_{\text{ext}}$ has its spin angular momentum $S$, antiparallel to $\vec{B}_{\text{ext}}$. If the electron undergoes a spin-flip so that $S$ is then parallel with $\vec{B}_{\text{ext}}$, must energy be supplied to or lost by the electron?

Does the magnitude of the net force on the current loop of Figs. 32-12a and b increase, decrease, or remain the same if we increase (a) the magnitude of $\vec{B}_{\text{ext}}$ and (b) the divergence of $\vec{B}_{\text{ext}}$?

Figure 32-23 shows a face-on view of one of the two square plates of a parallel-plate capacitor, as well as four loops that are located between the plates. The capacitor is being discharged. (a) Neglecting fringing of the magnetic field, rank the loops according to the magnitude of $\oint \vec{B} \cdot d\vec{s}$ along them, greatest first. (b) Along which loop, if any, is the angle between the directions of $\vec{B}$ and $d\vec{s}$ constant (so that their dot product can easily be evaluated)? (c) Along which loop, if any, is $B$ constant (so that $B$ can be brought in front of the integral sign in Eq. 32-3)?

Figure 32-24 shows three loop models of an electron orbiting counterclockwise within a magnetic field. The fields are nonuniform for models 1 and 2 and uniform for model 3. For each model, are (a) the magnetic dipole moment of the loop and (b) the magnetic force on the loop directed up, directed down, or zero?

Replace the current loops of Question 8 and Fig. 32-24 with diamagnetic spheres. For each field, are (a) the magnetic dipole moment of the sphere and (b) the magnetic force on the sphere directed up, directed down, or zero?

Replace the current loops of Question 8 and Fig. 32-24 with paramagnetic spheres. For each field, are (a) the magnetic dipole moment of the sphere and (b) the magnetic force on the sphere directed up, directed down, or zero?

Figure 32-25 represents three rectangular samples of a ferromagnetic material in which the magnetic dipoles of the domains have been directed out of the page (encircled dot) by a very strong applied field $B_0$. In each sample, an island domain still has its magnetic field directed into the page (encircled $\times$). Sample 1 is one (pure) crystal. The other samples contain impurities collected along lines; domains cannot easily spread across such lines.

The applied field is now to be reversed and its magnitude kept moderate. The change causes the island domain to grow. (a) Rank the three samples according to the success of that growth, greatest growth first. Ferromagnetic materials in which the magnetic dipoles are easily changed are said to be magnetically soft; when the changes are difficult, requiring strong applied fields, the materials are said to be magnetically hard. (b) Of the three samples, which is the most magnetically hard?

Figure 32-26 shows four steel bars; three are permanent magnets. One of the poles is indicated. Through experiment we find that ends $a$ and $d$ attract each other, ends $e$ and $f$ repel, ends $e$ and $h$ attract, and ends $a$ and $h$ attract. (a) Which ends are north poles? (b) Which bar is not a magnet?
Module 32-1 Gauss’ Law for Magnetic Fields

1. The magnetic flux through each of five faces of a die (singular of “dice”) is given by \( \Phi_B = \pm N \text{ Wb} \), where \( N \) (\( N = 1 \) to 5) is the number of spots on the face. The flux is positive (outward) for \( N \) even and negative (inward) for \( N \) odd. What is the flux through the sixth face of the die?

2. Figure 32-27 shows a closed surface. Along the flat top face, which has a radius of 2.0 cm, a perpendicular magnetic field \( B \) of magnitude 0.30 T is directed outward. Along the flat bottom face, a magnetic flux of 0.70 mWb is directed outward. What are the (a) magnitude and (b) direction (inward or outward) of the magnetic flux through the curved part of the surface?

3. A Gaussian surface in the shape of a right circular cylinder with end caps has a radius of 12 cm and a length of 80 cm. Through one end there is an inward magnetic flux of 25.0 \( \mu \text{Wb} \). At the other end there is a uniform magnetic field of 1.60 mT, normal to the surface and directed outward. What are the (a) magnitude and (b) direction (inward or outward) of the net magnetic flux through the curved surface?

4. Two wires, parallel to a z axis and a distance 4\( r \) apart, carry equal currents \( i \) in opposite directions, as shown in Fig. 32-28. A circular cylinder of radius \( r \) and length \( L \) has its axis on the z axis, midway between the wires. Use Gauss’ law for magnetism to derive an expression for the net outward magnetic flux through the half of the cylindrical surface above the \( x \) axis. (Hint: Find the flux through the portion of the \( xz \) plane that lies within the cylinder.)

Module 32-2 Induced Magnetic Fields

5. The induced magnetic field at radial distance 6.0 mm from the central axis of a circular parallel-plate capacitor is \( 2.0 \times 10^{-7} \text{ T} \). The plates have radius 3.0 mm. At what rate \( dE/dt \) is the electric field between the plates changing?

6. A capacitor with square plates of edge length \( L \) is being discharged by a current of 0.75 A. Figure 32-29 is a head-on view of one of the plates from inside the capacitor. A dashed rectangular path is shown. If \( L = 12 \text{ cm}, W = 4.0 \text{ cm}, \) and \( H = 2.0 \text{ cm}, \) what is the value of \( \oint B \cdot ds \) around the dashed path?

7. Uniform electric flux. Figure 32-30 shows a circular region of radius \( R = 3.00 \text{ cm} \) in which a uniform electric flux is directed out of the plane of the page. The total electric flux through the region is given by \( \Phi_E = (3.00 \text{ mV} \cdot \text{m/s})r \), where \( r \) is in seconds. What is the magnitude of the magnetic field that is induced at radial distances (a) 2.00 cm and (b) 5.00 cm?

8. Nonuniform electric flux. Figure 32-30 shows a circular region of radius \( R = 3.00 \text{ cm} \) in which an electric flux is directed out of the plane of the page. The flux encircled by a concentric circle of radius \( r \) is given by \( \Phi_E = (0.600 \text{ V} \cdot \text{m/s})(r/R)t \), where \( r \leq R \) and \( t \) is in seconds. What is the magnitude of the induced magnetic field at radial distances (a) 2.00 cm and (b) 5.00 cm?

9. Uniform electric field. In Fig. 32-30, a uniform electric field is directed out of the page within a circular region of radius \( R = 3.00 \text{ cm} \). The field magnitude is given by \( E = (4.50 \times 10^{-3} \text{ V/m} \cdot \text{s})t \), where \( r \) is in seconds. What is the magnitude of the induced magnetic field at radial distances (a) 2.00 cm and (b) 5.00 cm?

10. Nonuniform electric field. In Fig. 32-30, an electric field is directed out of the page within a circular region of radius \( R = 3.00 \text{ cm} \). The field magnitude is \( E = (0.500 \text{ V/m} \cdot \text{s})(1 - r/R)t \), where \( t \) is in seconds and \( r \) is the radial distance \( (r \leq R) \). What is the magnitude of the induced magnetic field at radial distances (a) 2.00 cm and (b) 5.00 cm?

11. Suppose that a parallel-plate capacitor has circular plates with radius \( R = 30 \text{ mm} \) and a plate separation of 5.0 mm. Suppose also that a sinusoidal potential difference with a maximum value of 150 V and a frequency of 60 Hz is applied across the plates; that is,

\[
V = (150 \text{ V}) \sin[2\pi(60 \text{ Hz})t].
\]

(a) Find \( B_{\text{max}}(R) \), the maximum value of the induced magnetic field that occurs at \( r = R \). (b) Plot \( B_{\text{max}}(r) \) for \( 0 < r < 10 \text{ cm} \).

12. A parallel-plate capacitor with circular plates of radius 40 mm is being discharged by a current of 6.0 A. At what radius (a) inside and (b) outside the capacitor gap is the magnitude of the induced magnetic field equal to 75% of its maximum value? (c) What is that maximum value?

Module 32-3 Displacement Current

13. At what rate must the potential difference between the plates of a parallel-plate capacitor with a 2.0 \( \mu \text{F} \) capacitance be changed to produce a displacement current of 1.5 A?

14. A parallel-plate capacitor with circular plates of radius \( R \) is being charged. Show that the magnitude of the current density of the displacement current is \( J_y = e_i(dE/dt) \) for \( r \leq R \).

15. Prove that the displacement current in a parallel-plate capacitor of capacitance \( C \) can be written as \( i_d = C(dV/dt) \), where \( V \) is the potential difference between the plates.

16. A parallel-plate capacitor with circular plates of radius 0.10 m is being discharged. A circular loop of radius 0.20 m is concentric
with the capacitor and halfway between the plates. The displacement current through the loop is 2.0 A. At what rate is the electric field between the plates changing?

**Problem 17** A silver wire has resistivity \( \rho = 1.62 \times 10^{-8} \, \Omega \cdot \text{m} \) and a cross-sectional area of 5.00 mm\(^2\). The current in the wire is uniform and changing at the rate of 2000 A/s when the current is 100 A. (a) What is the magnitude of the (uniform) electric field in the wire when the current in the wire is 100 A? (b) What is the displacement current in the wire at that time? (c) What is the ratio of the magnitude of the magnetic field due to the displacement current to that due to the current at a distance \( r \) from the wire?

**Problem 18** The circuit in Fig. 32-31 consists of switch S, a 12.0 V ideal battery, a 20.0 M\( \Omega \) resistor, and an air-filled capacitor. The capacitor has parallel circular plates of radius 5.00 cm, separated by 3.00 mm. At time \( t = 0 \), switch S is closed to begin charging the capacitor. The electric field between the plates is uniform. At \( t = 250 \, \mu s \), what is the magnitude of the magnetic field within the capacitor, at radial distance 3.00 cm?

**Problem 19** Uniform displacement-current density. Figure 32-30 shows a circular region of radius \( R = 3.00 \, \text{cm} \) in which a displacement current is directed out of the page. The displacement current has a uniform density of magnitude \( J_d = 6.00 \, \text{A/m}^2 \). What is the magnitude of the magnetic field due to the displacement current at radial distances (a) 2.00 cm and (b) 5.00 cm?

**Problem 20** Uniform displacement current. Figure 32-30 shows a circular region of radius \( R = 3.00 \, \text{cm} \) in which a uniform displacement current \( i_d = 0.500 \, \text{A} \) is out of the page. What is the magnitude of the magnetic field due to the displacement current at radial distances (a) 2.00 cm and (b) 5.00 cm?

**Problem 21** Nonuniform displacement-current density. Figure 32-30 shows a circular region of radius \( R = 3.00 \, \text{cm} \) in which a displacement current is directed out of the page. The magnitude of the density of this displacement current is \( J_d = (4.00 \, \text{A/m}^2)(1 - r/R) \), where \( r \) is the radial distance \( (r \leq R) \). What is the magnitude of the magnetic field due to the displacement current at (a) \( r = 2.00 \, \text{cm} \) and (b) \( r = 5.00 \, \text{cm} \)?

**Problem 22** Nonuniform displacement current. Figure 32-30 shows a circular region of radius \( R = 3.00 \, \text{cm} \) in which a displacement current \( i_d \) is directed out of the figure. The magnitude of the displacement current is \( i_d = (3.00 \, \text{A})(r/R) \), where \( r \) is the radial distance \( (r \leq R) \) from the center. What is the magnitude of the magnetic field due to \( i_d \) at radial distances (a) 2.00 cm and (b) 5.00 cm?

**Problem 23** SSM ILW In Fig. 32-32, a parallel-plate capacitor has square plates of edge length \( L = 1.0 \, \text{m} \). A current of 2.0 A charges the capacitor, producing a uniform electric field \( \vec{E} \) between the plates, with \( \vec{E} \) perpendicular to the plates. (a) What is the displacement current \( i_d \) through the region between the plates? (b) What is \( d\vec{E}/dt \) in this region? (c) What is the displacement current encircled by the square dashed path of edge length \( d = 0.50 \, \text{m} \)? (d) What is the value of \( \oint \vec{B} \cdot d\vec{s} \) around this square dashed path?

**Problem 24** The magnitude of the electric field between the two circular parallel plates in Fig. 32-33 is \( \vec{E} = (4.0 \times 10^3) - (6.0 \times 10^4) \), with \( \vec{E} \) in volts per meter and \( t \) in seconds. At \( t = 0 \), \( \vec{E} \) is upward. The plate area is \( 4.0 \times 10^{-2} \, \text{m}^2 \). For \( t \neq 0 \), what are the (a) magnitude and (b) direction (up or down) of the displacement current between the plates and (c) is the direction of the induced magnetic field clockwise or counterclockwise in the figure?

**Problem 25** ILW As a parallel-plate capacitor with circular plates 20 cm in diameter is being charged, the current density of the displacement current in the region between the plates is uniform and has a magnitude of 20 A/m\(^2\). (a) Calculate the magnitude \( B \) of the magnetic field at a distance \( r = 50 \, \text{mm} \) from the axis of symmetry of this region. (b) Calculate \( dE/dt \) in this region.

**Problem 26** A capacitor with parallel circular plates of radius \( R = 1.20 \, \text{cm} \) is discharging via a current of 12.0 A. Consider a loop of radius \( R/3 \) that is centered on the central axis between the plates. (a) How much displacement current is encircled by the loop? The maximum induced magnetic field has a magnitude of 12.0 mT. At what radius (b) inside and (c) outside the capacitor gap is the magnitude of the induced magnetic field 3.00 mT?

**Problem 27** ILW In Fig. 32-34, a uniform electric field \( \vec{E} \) collapses. The vertical axis scale is set by \( E_x = 6.0 \times 10^5 \, \text{N/C} \), and the horizontal axis scale is set by \( i_t = 12.0 \, \mu \text{s} \). Calculate the magnitude of the displacement current through a 1.6 m\(^2\) area perpendicular to the field during each of the time intervals \( a, b, \) and \( c \) shown on the graph. (Ignore the behavior at the ends of the intervals.)

**Problem 28** ILW Figure 32-35a shows the current \( i \) that is produced in a wire of resistivity \( 1.62 \times 10^{-8} \, \Omega \cdot \text{m} \) in diameter. The magnitude of the current versus time \( t \) is shown in Fig. 32-35b. The vertical axis scale is set by \( i_t = 10.0 \, \text{A} \), and the horizontal axis scale is set by \( t \, \mu \text{s} \). Point \( P \) is at radial distance 9.00 mm from the wire’s center. Determine the magnitude of the magnetic field \( \vec{B} \) at point \( P \) due to the actual current \( i \) in the wire at (a) \( t = 20 \, \mu \text{s} \), (b) \( t = 40 \, \mu \text{s} \), and (c) \( t = 60 \, \mu \text{s} \). Next, assume that the electric field driving the current is confined to the wire. Then determine the magnitude of the magnetic field \( \vec{B}_{\text{mag}} \) at point \( P \) due to the displacement current \( i_d \) in the wire at (d) \( t = 20 \, \mu \text{s} \), (e) \( t = 40 \, \mu \text{s} \), and (f) \( t = 60 \, \mu \text{s} \). At point \( P \) at \( t = 20 \, \mu \text{s} \), what is the direction (into or out of the page) of (g) \( \vec{B}_i \) and (h) \( \vec{B}_d \)?

**Problem 29** Figure 32-36 shows a circular plates of radius \( R = 18.0 \, \text{cm} \). A current of 120 A through the region between the plates. The displacement current through the loop is 2.0 A. At what rate is the electric field between the plates changing?
Module 32-4 Magnets

Assume the average value of the vertical component of Earth’s magnetic field is 43 \mu T (downward) for all of Arizona, which has an area of 2.95 \times 10^7 \text{ km}^2. What then are the (a) magnitude and (b) direction (inward or outward) of the net magnetic flux through the rest of Earth’s surface (the entire surface excluding Arizona)?

In New Hampshire the average horizontal component of Earth’s magnetic field in 1912 was 16 \mu T, and the average inclination or “dip” was 73°. What was the corresponding magnitude of Earth’s magnetic field?

Module 32-5 Magnetism and Electrons

If an electron in an atom has an orbital angular momentum with \( m = 0 \), what are the components (a) \( L_{orb,z} \) and (b) \( \mu_{orb,z} \)? If the atom is in an external magnetic field \( \vec{B} \) that has magnitude 35 mT and is directed along the z axis, what are (c) the energy \( U_{orb} \) associated with \( \mu_{orb} \) and (d) the energy \( U_{spin} \) associated with \( \mu_{spin} \)? If, instead, the electron has \( m = -3 \), what are (e) \( L_{orb,z} \), (f) \( \mu_{orb,z} \), (g) \( U_{orb} \), and (h) \( U_{spin} \)?

What is the energy difference between parallel and antiparallel alignment of the z component of an electron’s spin magnetic dipole moment with an external magnetic field of magnitude 0.25 T, directed parallel to the z axis?

What is the measured component of the orbital magnetic dipole moment of an electron with (a) \( m_z = 1 \) and (b) \( m_z = -2 \)?

An electron is placed in a magnetic field \( \vec{B} \) that is directed along a z axis. The energy difference between parallel and antiparallel alignments of the z component of the electron’s spin magnetic moment with \( \vec{B} \) is 6.00 \times 10^{-25} \text{ J}. What is the magnitude of \( \vec{B} \)?

Module 32-6 Diamagnetism

Figure 32-37 gives the magnetization curve for a paramagnetic material. The vertical axis scale is set by \( a = 0.15 \), and the horizontal axis scale is set by \( b = 0.2 \text{T/K} \). Let \( \mu_{sat} \) be the measured net magnetic moment of a sample of the material and \( \mu_{max} \) be the maximum possible net magnetic moment of that sample. According to Curie’s law, what would be the ratio \( \mu_{sat}/\mu_{max} \)?

Consider a solid containing \( N \) atoms per unit volume, each atom having a magnetic dipole moment \( \vec{\mu} \). Suppose the direction of \( \vec{\mu} \) can be only parallel or antiparallel to an externally
applied magnetic field $\vec{B}$ (this will be the case if $\vec{\mu}$ is due to the spin of a single electron). According to statistical mechanics, the probability of an atom being in a state with energy $U$ is proportional to $e^{-U/kT}$, where $T$ is the temperature and $k$ is Boltzmann’s constant. Thus, because energy $U = -\vec{\mu} \cdot \vec{B}$, the fraction of atoms whose dipole moment is parallel to $\vec{B}$ is proportional to $e^{\mu B/kT}$ and the fraction of atoms whose dipole moment is antiparallel to $\vec{B}$ is proportional to $e^{-\mu B/kT}$.

(a) Show that the magnitude of the magnetization of this solid is $M = N\mu \tanh(\mu B/kT)$. Here $\tanh$ is the hyperbolic tangent function: $\tanh(x) = (e^x - e^{-x})/(e^x + e^{-x})$. (b) Show that the result given in (a) reduces to $M = N\mu B/kT$ for $\mu B \ll kT$. (c) Show that the result of (a) reduces to $M = N\mu$ for $\mu B \gg kT$. (d) Show that both (b) and (c) agree qualitatively with Fig. 32-14.

Additional Problems

54 Using the approximations given in Problem 61, find (a) the altitude above Earth’s surface where the magnitude of its magnetic field is 50.0% of the surface value at the same latitude; (b) the maximum magnitude of the magnetic field at the core–mantle boundary, 2900 km below Earth’s surface; and the (c) magnitude and (d) inclination of Earth’s magnetic field at the north geographic pole. (e) Suggest why the values you calculated for (c) and (d) differ from measured values.

55 Earth has a magnetic dipole moment of $8.0 \times 10^{22}$ J/T. (a) What current would have to be produced in a single turn of wire extending around Earth at its geomagnetic equator if we wished to set up such a dipole? Could such an arrangement be used to cancel out Earth’s magnetism? (b) At points in space well above Earth’s surface or (c) on Earth’s surface?

56 A charge $q$ is distributed uniformly around a thin ring of radius $r$. The ring is rotating about an axis through its center and perpendicular to its plane, at an angular speed $\omega$. (a) Show that the magnetic moment due to the rotating charge has magnitude $\mu = \frac{1}{2}q\omega r^2$. (b) What is the direction of this magnetic moment if the charge is positive?

57 A magnetic compass has its needle, of mass 0.050 kg and length 4.0 cm, aligned with the horizontal component of Earth’s magnetic field at a place where component has the value $B_x = 16 \mu T$. After the compass is given a momentary gentle shake, the needle oscillates with angular frequency $\omega = 45$ rad/s. Assuming that the needle is a uniform thin rod mounted at its center, find the magnitude of its magnetic dipole moment.

58 The capacitor in Fig. 32-7 is being charged with a 2.50 A current. The wire radius is 1.50 mm, and the plate radius is 2.00 cm. Assume that the current $i$ in the wire and the displacement current $i_d$ in the capacitor gap are both uniformly distributed. What is the magnitude of the magnetic field due to $i_d$ at the following radial distances from the wire’s center: (a) 1.00 mm (inside the wire), (b) 3.00 mm (outside the wire), and (c) 2.20 cm (outside the gap)? What is the magnitude of the magnetic field due to $i_d$ at the following radial distances from the central axis between the plates: (d) 1.00 mm (inside the gap), (e) 3.00 mm (inside the gap), and (f) 2.20 cm (outside the gap)? (g) Explain why the fields at the two smaller radii are so different for the wire and the gap but the fields at the largest radius are not.

59 A parallel-plate capacitor with circular plates of radius $R = 16$ mm and gap width $d = 5.0$ mm has a uniform electric field between the plates. Starting at time $t = 0$, the potential difference between the two plates is $V = (100 \text{ V})e^{-t/\tau}$, where the time constant $\tau = 12$ ms. At radial distance $r = 0.80R$ from the central axis,
what is the magnetic field magnitude (a) as a function of time for \( t \geq 0 \) and (b) at time \( t = 3\pi \)?

60 A magnetic flux of 7.0 mWb is directed outward through the flat bottom face of the closed surface shown in Fig. 32-40. Along the flat top face (which has a radius of 4.2 cm) there is a 0.40 T magnetic field \( \vec{B} \) directed perpendicular to the face. What are the (a) magnitude and (b) direction (inward or outward) of the magnetic flux through the curved part of the surface?

61 SSM The magnetic field of Earth can be approximated as the magnetic field of a dipole. The horizontal and vertical components of this field at any distance \( r \) from Earth’s center are given by

\[
B_h = \frac{\mu_0 \mu}{4\pi^3} \cos \lambda_m, \quad B_v = \frac{\mu_0 \mu}{2\pi^3} \sin \lambda_m,
\]

where \( \lambda_m \) is the magnetic latitude (this type of latitude is measured from the geomagnetic equator toward the north or south geomagnetic pole). Assume that Earth’s magnetic dipole moment has magnitude \( \mu = 8.00 \times 10^{22} \) A·m². (a) Show that the magnitude of Earth’s field at latitude \( \lambda_m \) is given by

\[
B = \frac{\mu_0 \mu}{4\pi^3} \sqrt{1 + 3 \sin^2 \lambda_m}
\]

(b) Show that the inclination \( \phi_l \) of the magnetic field is related to the magnetic latitude \( \lambda_m \) by \( \tan \phi_l = 2 \tan \lambda_m \).

62 Use the results displayed in Problem 61 to predict the (a) magnitude and (b) inclination of Earth’s magnetic field at the geomagnetic equator, the (c) magnitude and (d) inclination at geomagnetic latitude 60.0°, and the (e) magnitude and (f) inclination at the north geomagnetic pole.

63 A parallel-plate capacitor with circular plates of radius 55.0 mm is being charged. At what radius (a) inside and (b) outside the capacitor gap is the magnetic field equal to 50.0% of its maximum value?

64 A sample of the paramagnetic salt to which the magnetization curve of Fig. 32-14 applies is immersed in a uniform magnetic field of 2.0 T. At what temperature will the degree of magnetic saturation of the sample be (a) 50% and (b) 90%?

65 A parallel-plate capacitor with circular plates of radius \( R \) is being discharged. The displacement current through a central circular area, parallel to the plates and with radius \( R/2 \), is 2.0 A. What is the discharging current?

66 Figure 32-41 gives the variation of an electric field that is perpendicular to a circular area of 2.0 m². During the time period shown, what is the greatest displacement current through the area?

67 In Fig. 32-42, a parallel-plate capacitor is being discharged by a current \( i = 5.0 \) A. The plates are square with edge length \( L = 8.0 \) mm. (a) What is the rate at which the electric field between the plates is changing? (b) What is the value of \( \oint \vec{B} \cdot d\vec{s} \) around the dashed path, where \( H = 2.0 \) mm and \( W = 3.0 \) mm?

68 What is the measured component of the orbital magnetic dipole moment of an electron with the values (a) \( m_\ell = 3 \) and (b) \( m_\ell = -4 \)?

69 In Fig. 32-43, a bar magnet lies near a paper cylinder. (a) Sketch the magnetic field lines that pass through the surface of the cylinder. (b) What is the sign of \( \vec{B} \cdot d\vec{A} \) for every area \( d\vec{A} \) on the surface? (c) Does this contradict Gauss’ law for magnetism? Explain.

70 In the lowest energy state of the hydrogen atom, the most probable distance of the single electron from the central proton (the nucleus) is \( 5.2 \times 10^{-11} \) m. (a) Compute the magnitude of the proton’s electric field at that distance. The component \( \mu_\ell \) of the proton’s spin magnetic dipole moment measured on a \( z \) axis is \( 1.4 \times 10^{-26} \) J/T. (b) Compute the magnitude of the proton’s magnetic field at the distance \( 5.2 \times 10^{-11} \) m on the \( z \) axis. (Hint: Use Eq. 29-27.) (c) What is the ratio of the spin magnetic dipole moment of the electron to that of the proton?

71 Figure 32-38 shows a loop model (loop \( L \)) for a paramagnetic material. (a) Sketch the field lines through and about the material due to the magnet. What is the direction of (b) the loop’s net magnetic dipole moment \( \mu \), (c) the conventional current \( i \) in the loop (clockwise or counterclockwise in the figure), and (d) the magnetic force acting on the loop?

72 Two plates (as in Fig. 32-7) are being discharged by a constant current. Each plate has a radius of 4.00 cm. During the discharging, at a point between the plates at radial distance 2.00 cm from the central axis, the magnetic field has a magnitude of 12.5 nT. (a) What is the magnitude of the magnetic field at radial distance 6.00 cm? (b) What is the current in the wires attached to the plates?

73 SSM If an electron in an atom has orbital angular momentum with \( m_\ell \) values limited by \( \pm 3 \), how many values of (a) \( L_{orb,z} \) and (b) \( \mu_{orb,z} \) can the electron have? In terms of \( h, m, \) and \( e \), what is the greatest allowed magnitude for (c) \( L_{orb,z} \) and (d) \( \mu_{orb,z} \)? (e) What is the greatest allowed magnitude for the \( z \) component of the electron’s net angular momentum (orbital plus spin)? (f) How many values (signs included) are allowed for the \( z \) component of its net angular momentum?

74 A parallel-plate capacitor with circular plates is being charged. Consider a circular loop centered on the central axis and located between the plates. If the loop radius of 3.00 cm is greater than the plate radius, what is the displacement current between the plates when the magnetic field along the loop has magnitude 2.00 \( \mu \)T?

75 Suppose that \( \pm 4 \) are the limits to the values of \( m_\ell \) for an electron in an atom. (a) How many different values of the electron’s \( \mu_{orb,z} \) are possible? (b) What is the greatest magnitude of those possible values? Next, if the atom is in a magnetic field of magnitude 0.250 T, in the positive direction of the \( z \) axis, what are (c) the maximum energy and (d) the minimum energy associated with those possible values of \( \mu_{orb,z} \)?

76 What are the measured components of the orbital magnetic dipole moment of an electron with (a) \( m_\ell = 3 \) and (b) \( m_\ell = -4 \)?
CHAPTER 33
Electromagnetic Waves

33-1 ELECTROMAGNETIC WAVES

Learning Objectives

After reading this module, you should be able to . . .

33.01 In the electromagnetic spectrum, identify the relative wavelengths (longer or shorter) of AM radio, FM radio, television, infrared light, visible light, ultraviolet light, x rays, and gamma rays.

33.02 Describe the transmission of an electromagnetic wave by an LC oscillator and an antenna.

33.03 For a transmitter with an LC oscillator, apply the relationships between the oscillator’s inductance \( L \), capacitance \( C \), and angular frequency \( \omega \), and the emitted wave’s frequency \( f \) and wavelength \( \lambda \).

33.04 Identify the speed of an electromagnetic wave in vacuum (and approximately in air).

33.05 Identify that electromagnetic waves do not require a medium and can travel through vacuum.

33.06 Apply the relationship between the speed of an electromagnetic wave, the straight-line distance traveled by the wave, and the time required for the travel.

33.07 Apply the relationships between an electromagnetic wave’s frequency \( f \), wavelength \( \lambda \), period \( T \), angular frequency \( \omega \), and speed \( c \).

33.08 Identify that an electromagnetic wave consists of an electric component and a magnetic component that are (a) perpendicular to the direction of travel, (b) perpendicular to each other, and (c) sinusoidal waves with the same frequency and phase.

33.09 Apply the sinusoidal equations for the electric and magnetic components of an EM wave, written as functions of position and time.

33.10 Apply the relationship between the speed of light \( c \), the permittivity constant \( \varepsilon_0 \), and the permeability constant \( \mu_0 \).

33.11 For any instant and position, apply the relationship between the electric field magnitude \( E \), the magnetic field magnitude \( B \), and the speed of light \( c \).

33.12 Describe the derivation of the relationship between the speed of light \( c \) and the ratio of the electric field amplitude \( E \) to the magnetic field amplitude \( B \).

Key Ideas

- An electromagnetic wave consists of oscillating electric and magnetic fields.
- The various possible frequencies of electromagnetic waves form a spectrum, a small part of which is visible light.
- An electromagnetic wave traveling along an \( x \) axis has an electric field \( \vec{E} \) and a magnetic field \( \vec{B} \) with magnitudes that depend on \( x \) and \( t \):
  \[
  E = E_m \sin(kx - \omega t)
  \]
  and
  \[
  B = B_m \sin(kx - \omega t),
  \]
  where \( E_m \) and \( B_m \) are the amplitudes of \( \vec{E} \) and \( \vec{B} \). The electric field induces the magnetic field and vice versa.
- The speed of any electromagnetic wave in vacuum is \( c \), which can be written as
  \[
  c = \frac{E}{B} = \frac{1}{\sqrt{\mu_0 \varepsilon_0}},
  \]
  where \( E \) and \( B \) are the simultaneous magnitudes of the fields.

What Is Physics?

The information age in which we live is based almost entirely on the physics of electromagnetic waves. Like it or not, we are now globally connected by television, telephones, and the web. And like it or not, we are constantly immersed in those signals because of television, radio, and telephone transmitters.

Much of this global interconnection of information processors was not imagined by even the most visionary engineers of 40 years ago. The challenge for
today’s engineers is trying to envision what the global interconnection will be like 40 years from now. The starting point in meeting that challenge is understanding the basic physics of electromagnetic waves, which come in so many different types that they are poetically said to form Maxwell’s rainbow.

**Maxwell’s Rainbow**

The crowning achievement of James Clerk Maxwell (see Chapter 32) was to show that a beam of light is a traveling wave of electric and magnetic fields—an **electromagnetic wave**—and thus that optics, the study of visible light, is a branch of electromagnetism. In this chapter we move from one to the other; we conclude our discussion of strictly electrical and magnetic phenomena, and we build a foundation for optics.

In Maxwell’s time (the mid 1800s), the visible, infrared, and ultraviolet forms of light were the only electromagnetic waves known. Spurred on by Maxwell’s work, however, Heinrich Hertz discovered what we now call radio waves and verified that they move through the laboratory at the same speed as visible light, indicating that they have the same basic nature as visible light.

As Fig. 33-1 shows, we now know a wide **spectrum** (or range) of electromagnetic waves: Maxwell’s rainbow. Consider the extent to which we are immersed in electromagnetic waves throughout this spectrum. The Sun, whose radiations define the environment in which we as a species have evolved and adapted, is the dominant source. We are also crisscrossed by radio and television signals. Microwaves from radar systems and from telephone relay systems may reach us. There are electromagnetic waves from lightbulbs, from the heated engine blocks of automobiles, from x-ray machines, from lightning flashes, and from buried radioactive materials. Beyond this, radiation reaches us from stars and other objects in our galaxy and from other galaxies. Electromagnetic waves also travel in the other direction. Television signals, transmitted from Earth since about 1950, have now taken news about us (along with episodes of I Love Lucy, albeit very faintly) to whatever technically sophisticated inhabitants there may be on whatever planets may encircle the nearest 400 or so stars.

![Figure 33-1 The electromagnetic spectrum.](image-url)
In the wavelength scale in Fig. 33-1 (and similarly the corresponding frequency scale), each scale marker represents a change in wavelength (and correspondingly in frequency) by a factor of 10. The scale is open-ended; the wavelengths of electromagnetic waves have no inherent upper or lower bound.

Certain regions of the electromagnetic spectrum in Fig. 33-1 are identified by familiar labels, such as *x rays* and *radio waves*. These labels denote roughly defined wavelength ranges within which certain kinds of sources and detectors of electromagnetic waves are in common use. Other regions of Fig. 33-1, such as those labeled TV channels and AM radio, represent specific wavelength bands assigned by law for certain commercial or other purposes. There are no gaps in the electromagnetic spectrum—and all electromagnetic waves, no matter where they lie in the spectrum, travel through *free space* (vacuum) with the same speed $c$.

The visible region of the spectrum is of course of particular interest to us. Figure 33-2 shows the relative sensitivity of the human eye to light of various wavelengths. The center of the visible region is about 555 nm, which produces the sensation that we call yellow-green.

The limits of this visible spectrum are not well defined because the eye sensitivity curve approaches the zero-sensitivity line asymptotically at both long and short wavelengths. If we take the limits, arbitrarily, as the wavelengths at which eye sensitivity has dropped to 1% of its maximum value, these limits are about 430 and 690 nm; however, the eye can detect electromagnetic waves somewhat beyond these limits if they are intense enough.

**The Traveling Electromagnetic Wave, Qualitatively**

Some electromagnetic waves, including *x rays*, *gamma rays*, and *visible light*, are radiated (emitted) from sources that are of atomic or nuclear size, where quantum physics rules. Here we discuss how other electromagnetic waves are generated. To simplify matters, we restrict ourselves to that region of the spectrum (wavelength $\lambda \approx 1$ m) in which the source of the radiation (the emitted waves) is both macroscopic and of manageable dimensions.

Figure 33-3 shows, in broad outline, the generation of such waves. At its heart is an *LC oscillator*, which establishes an angular frequency $\omega (= 1/\sqrt{LC})$. Charges and currents in this circuit vary sinusoidally at this frequency, as depicted in Fig. 31-1. An external source—possibly an ac generator—must be included to supply energy to compensate both for thermal losses in the circuit and for energy carried away by the radiated electromagnetic wave.

The *LC* oscillator of Fig. 33-3 is coupled by a transformer and a transmission line to an *antenna*, which consists essentially of two thin, solid, conducting rods. Through this coupling, the sinusoidally varying current in the oscillator causes charge to oscillate sinusoidally along the rods of the antenna at the angular frequency $\omega$ of the *LC* oscillator. The current in the rods associated with this movement of charge also varies sinusoidally, in magnitude and direction, at angular frequency $\omega$. The antenna has the effect of an electric dipole whose electric dipole moment varies sinusoidally in magnitude and direction along the antenna.
Because the dipole moment varies in magnitude and direction, the electric field produced by the dipole varies in magnitude and direction. Also, because the current varies, the magnetic field produced by the current varies in magnitude and direction. However, the changes in the electric and magnetic fields do not happen everywhere instantaneously; rather, the changes travel outward from the antenna at the speed of light \( c \). Together the changing fields form an electromagnetic wave that travels away from the antenna at speed \( c \). The angular frequency of this wave is \( \omega \), the same as that of the LC oscillator.

**Electromagnetic Wave.** Figure 33-4 shows how the electric field \( \vec{E} \) and the magnetic field \( \vec{B} \) change with time as one wavelength of the wave sweeps past the distant point \( P \) of Fig. 33-3; in each part of Fig. 33-4, the wave is traveling directly out of the page. (We choose a distant point so that the curvature of the waves suggested in Fig. 33-3 is small enough to neglect. At such points, the wave is said to be a plane wave, and discussion of the wave is much simplified.) Note several key features in Fig. 33-4; they are present regardless of how the wave is created:

1. The electric and magnetic fields \( \vec{E} \) and \( \vec{B} \) are always perpendicular to the direction in which the wave is traveling. Thus, the wave is a transverse wave, as discussed in Chapter 16.
2. The electric field is always perpendicular to the magnetic field.
3. The cross product \( \vec{E} \times \vec{B} \) always gives the direction in which the wave travels.
4. The fields always vary sinusoidally, just like the transverse waves discussed in Chapter 16. Moreover, the fields vary with the same frequency and in phase (in step) with each other.

In keeping with these features, we can assume that the electromagnetic wave is traveling toward \( P \) in the positive direction of an \( x \) axis, that the electric field in Fig. 33-4 is oscillating parallel to the \( y \) axis, and that the magnetic field is then oscillating parallel to the \( z \) axis (using a right-handed coordinate system, of course). Then we can write the electric and magnetic fields as sinusoidal functions of position \( x \) (along the path of the wave) and time \( t \):

\[
E = E_m \sin(kx - \omega t), \quad (33-1)
\]

\[
B = B_m \sin(kx - \omega t), \quad (33-2)
\]

in which \( E_m \) and \( B_m \) are the amplitudes of the fields and, as in Chapter 16, \( \omega \) and \( k \) are the angular frequency and angular wave number of the wave, respectively. From these equations, we note that not only do the two fields form the electromagnetic wave but each also forms its own wave. Equation 33-1 gives the electric wave component of the electromagnetic wave, and Eq. 33-2 gives the magnetic wave component. As we shall discuss below, these two wave components cannot exist independently.

**Wave Speed.** From Eq. 16-13, we know that the speed of the wave is \( \omega/k \). However, because this is an electromagnetic wave, its speed (in vacuum) is given the symbol \( c \) rather than \( v \). In the next section you will see that \( c \) has the value

\[
c = \frac{1}{\sqrt{\mu_0\varepsilon_0}} \quad \text{(wave speed)}, \quad (33-3)
\]

which is about \( 3.0 \times 10^8 \) m/s. In other words,

> All electromagnetic waves, including visible light, have the same \( c \) in vacuum.

You will also see that the wave speed \( c \) and the amplitudes of the electric and
magnetic fields are related by

\[ \frac{E_m}{B_m} = c \quad \text{(amplitude ratio).} \tag{33-4} \]

If we divide Eq. 33-1 by Eq. 33-2 and then substitute with Eq. 33-4, we find that the magnitudes of the fields at every instant and at any point are related by

\[ \frac{E}{B} = c \quad \text{(magnitude ratio).} \tag{33-5} \]

**Rays and Wavefronts.** We can represent the electromagnetic wave as in Fig. 33-5a, with a ray (a directed line showing the wave’s direction of travel) or with wavefronts (imaginary surfaces over which the wave has the same magnitude of electric field), or both. The two wavefronts shown in Fig. 33-5a are separated by one wavelength \( \lambda (= 2\pi/k) \) of the wave. (Waves traveling in approximately the same direction form a beam, such as a laser beam, which can also be represented with a ray.)

**Drawing the Wave.** We can also represent the wave as in Fig. 33-5b, which shows the electric and magnetic field vectors in a “snapshot” of the wave at a certain instant. The curves through the tips of the vectors represent the sinusoidal oscillations given by Eqs. 33-1 and 33-2; the wave components \( \vec{E} \) and \( \vec{B} \) are in phase, perpendicular to each other, and perpendicular to the wave’s direction of travel.

Interpretation of Fig. 33-5b requires some care. The similar drawings for a transverse wave on a taut string that we discussed in Chapter 16 represented the up and down displacement of sections of the string as the wave passed (something actually moved). Figure 33-5b is more abstract. At the instant shown, the electric and magnetic fields each have a certain magnitude and direction (but always perpendicular to the \( x \) axis) at each point along the \( x \) axis. We choose to represent these vector quantities with a pair of arrows for each point, and so we must draw arrows of different lengths for different points, all directed away from the \( x \) axis, like thorns on a rose stem. However, the arrows represent field values only at points that are on the \( x \) axis. Neither the arrows nor the sinusoidal curves represent a sideways motion of anything, nor do the arrows connect points on the \( x \) axis with points off the axis.

**Feedback.** Drawings like Fig. 33-5 help us visualize what is actually a very complicated situation. First consider the magnetic field. Because it varies sinusoidally, it induces (via Faraday’s law of induction) a perpendicular electric field that also varies sinusoidally. However, because that electric field is varying sinusoidally, it induces (via Maxwell’s law of induction) a perpendicular magnetic field that also varies sinusoidally. And so on. The two fields continuously create each other via induction, and the resulting sinusoidal variations in the fields travel as a wave—the electromagnetic wave. Without this amazing result, we could not see; indeed, because we need electromagnetic waves.
from the Sun to maintain Earth’s temperature, without this result we could not even exist.

**A Most Curious Wave**

The waves we discussed in Chapters 16 and 17 require a medium (some material) through which or along which to travel. We had waves traveling along a string, through Earth, and through the air. However, an electromagnetic wave (let’s use the term light wave or light) is curiously different in that it requires no medium for its travel. It can, indeed, travel through a medium such as air or glass, but it can also travel through the vacuum of space between a star and us.

Once the special theory of relativity became accepted, long after Einstein published it in 1905, the speed of light waves was realized to be special. One reason is that light has the same speed regardless of the frame of reference from which it is measured. If you send a beam of light along an axis and ask several observers to measure its speed while they move at different speeds along that axis, either in the direction of the light or opposite it, they will all measure the same speed for the light. This result is an amazing one and quite different from what would have been found if those observers had measured the speed of any other type of wave; for other waves, the speed of the observers relative to the wave would have affected their measurements.

The meter has now been defined so that the speed of light (any electromagnetic wave) in vacuum has the exact value

\[ c = 299,792,458 \text{ m/s}, \]

which can be used as a standard. In fact, if you now measure the travel time of a pulse of light from one point to another, you are not really measuring the speed of the light but rather the distance between those two points.

**The Traveling Electromagnetic Wave, Quantitatively**

We shall now derive Eqs. 33-3 and 33-4 and, even more important, explore the dual induction of electric and magnetic fields that gives us light.

**Equation 33-4 and the Induced Electric Field**

The dashed rectangle of dimensions \( dx \) and \( h \) in Fig. 33-6 is fixed at point \( P \) on the \( x \) axis and in the \( xy \) plane (it is shown on the right in Fig. 33-5b). As the electromagnetic wave moves rightward past the rectangle, the magnetic flux \( \Phi_B \) through the rectangle changes and—according to Faraday’s law of induction—induced electric fields appear throughout the region of the rectangle. We take \( \vec{E} \) and \( \vec{E} + d\vec{E} \) to be the induced fields along the two long sides of the rectangle. These induced electric fields are, in fact, the electrical component of the electromagnetic wave.

Note the small red portion of the magnetic field component curve far from the \( y \) axis in Fig. 33-5b. Let’s consider the induced electric fields at the instant when this red portion of the magnetic component is passing through the rectangle. Just then, the magnetic field through the rectangle points in the positive \( z \) direction and is decreasing in magnitude (the magnitude was greater just before the red section arrived). Because the magnetic field is decreasing, the magnetic flux \( \Phi_B \) through the rectangle is also decreasing. According to Faraday’s law, this change in flux is opposed by induced electric fields, which produce a magnetic field \( \vec{B} \) in the positive \( z \) direction.

According to Lenz’s law, this in turn means that if we imagine the boundary of the rectangle to be a conducting loop, a counterclockwise induced current would have to appear in it. There is, of course, no conducting loop; but this analysis shows that the induced electric field vectors \( \vec{E} \) and \( \vec{E} + d\vec{E} \) are indeed

![Figure 33-6](image-url)
oriented as shown in Fig. 33-6, with the magnitude of \( \vec{E} + d\vec{E} \) greater than that of \( \vec{E} \). Otherwise, the net induced electric field would not act counterclockwise around the rectangle.

**Faraday’s Law.** Let us now apply Faraday’s law of induction,

\[
\oint \vec{E} \cdot d\vec{s} = -\frac{d\Phi_B}{dt},
\]  

(33-6)
counterclockwise around the rectangle of Fig. 33-6. There is no contribution to the integral from the top or bottom of the rectangle because \( \vec{E} \) and \( d\vec{s} \) are perpendicular to each other there. The integral then has the value

\[
\oint \vec{E} \cdot d\vec{s} = (E + dE)h - Eh = h \, dE.
\]  

(33-7)
The flux \( \Phi_B \) through this rectangle is

\[
\Phi_B = (B)(h \, dx),
\]  

(33-8)
where \( B \) is the average magnitude of \( \vec{B} \) within the rectangle and \( h \, dx \) is the area of the rectangle. Differentiating Eq. 33-8 with respect to \( t \) gives

\[
\frac{d\Phi_B}{dt} = h \, dx \frac{dB}{dt}.
\]  

(33-9)
If we substitute Eqs. 33-7 and 33-9 into Eq. 33-6, we find

\[
h \, dE = -h \, dx \frac{dB}{dt}
\]
or

\[
\frac{dE}{dx} = -\frac{dB}{dt}.
\]  

(33-10)
Actually, both \( B \) and \( E \) are functions of two variables, coordinate \( x \) and time \( t \), as Eqs. 33-1 and 33-2 show. However, in evaluating \( dE/dx \), we must assume that \( t \) is constant because Fig. 33-6 is an “instantaneous snapshot.” Also, in evaluating \( dB/dt \) we must assume that \( x \) is constant (a particular value) because we are dealing with the time rate of change of \( B \) at a particular place, the point \( P \) shown in Fig. 33-5b. The derivatives under these circumstances are partial derivatives, and Eq. 33-10 must be written

\[
\frac{\partial E}{\partial x} = -\frac{\partial B}{\partial t}.
\]  

(33-11)
The minus sign in this equation is appropriate and necessary because, although magnitude \( E \) is increasing with \( x \) at the site of the rectangle in Fig. 33-6, magnitude \( B \) is decreasing with \( t \).

From Eq. 33-1 we have

\[
\frac{\partial E}{\partial x} = k E_m \cos(kx - \omega t)
\]
and from Eq. 33-2

\[
\frac{\partial B}{\partial t} = -\omega B_m \cos(kx - \omega t).
\]
Then Eq. 33-11 reduces to

\[
k E_m \cos(kx - \omega t) = \omega B_m \cos(kx - \omega t),
\]  

(33-12)
The ratio \( \omega/k \) for a traveling wave is its speed, which we are calling \( c \). Equation 33-12 then becomes

\[
\frac{E_m}{B_m} = c \quad \text{(amplitude ratio)},
\]  

(33-13)
which is just Eq. 33-4.
Equation 33-3 and the Induced Magnetic Field

Figure 33-7 shows another dashed rectangle at point P of Fig. 33-5; this one is in the xz plane. As the electromagnetic wave moves rightward past this new rectangle, the electric flux $\Phi_E$ through the rectangle changes and—according to Maxwell’s law of induction—induced magnetic fields appear throughout the region of the rectangle. These induced magnetic fields are, in fact, the magnetic component of the electromagnetic wave.

We see from Fig. 33-5 that at the instant chosen for the magnetic field represented in Fig. 33-6, marked in red on the magnetic component curve, the electric field through the rectangle of Fig. 33-7 is directed as shown. Recall that at the chosen instant, the magnetic field in Fig. 33-6 is decreasing. Because the two fields are in phase, the electric field in Fig. 33-7 must also be decreasing, and so must the electric flux $\Phi_E$ through the rectangle. By applying the same reasoning we applied to Fig. 33-6, we see that the changing flux $\Phi_E$ will induce a magnetic field with vectors and oriented as shown in Fig. 33-7, where field $\vec{B}$ is greater than field $\vec{B}$.

Maxwell’s Law. Let us apply Maxwell’s law of induction,

\[
\oint \vec{B} \cdot d\vec{s} = \mu_0 \varepsilon_0 \frac{d\Phi_E}{dt}, \tag{33-14}
\]

by proceeding counterclockwise around the dashed rectangle of Fig. 33-7. Only the long sides of the rectangle contribute to the integral because the dot product along the short sides is zero. Thus, we can write

\[
\oint \vec{B} \cdot d\vec{s} = -(\vec{B} + d\vec{B})h + Bh = -h \, dB. \tag{33-15}
\]

The flux $\Phi_E$ through the rectangle is

\[
\Phi_E = (E)(h \, dx), \tag{33-16}
\]

where $E$ is the average magnitude of $\vec{E}$ within the rectangle. Differentiating Eq. 33-16 with respect to $t$ gives

\[
\frac{d\Phi_E}{dt} = h \, dx \, \frac{dE}{dt}.
\]

If we substitute this and Eq. 33-15 into Eq. 33-14, we find

\[
-h \, dB = \mu_0 \varepsilon_0 \left( h \, dx \, \frac{dE}{dt} \right)
\]

or, changing to partial-derivative notation as we did for Eq. 33-11,

\[
-\frac{\partial B}{\partial x} = \mu_0 \varepsilon_0 \frac{\partial E}{\partial t}. \tag{33-17}
\]

Again, the minus sign in this equation is necessary because, although $B$ is increasing with $x$ at point $P$ in the rectangle in Fig. 33-7, $E$ is decreasing with $t$.

Evaluating Eq. 33-17 by using Eqs. 33-1 and 33-2 leads to

\[-kB_m \cos(kx - \omega t) = -\mu_0 \varepsilon_0 \omega E_m \cos(kx - \omega t),\]

which we can write as

\[
\frac{E_m}{B_m} = \frac{1}{\mu_0 \varepsilon_0 \omega k} = \frac{1}{\mu_0 \varepsilon_0 \varepsilon_0}.
\]

Combining this with Eq. 33-13 leads at once to

\[
c = \frac{1}{\sqrt{\mu_0 \varepsilon_0}} \quad \text{(wave speed),} \tag{33-18}
\]

which is exactly Eq. 33-3.
Checkpoint 1

The magnetic field \( \vec{B} \) through the rectangle of Fig. 33-6 is shown at a different instant in part 1 of the figure here; \( \vec{B} \) is directed in the \( xz \) plane, parallel to the \( z \) axis, and its magnitude is increasing. (a) Complete part 1 by drawing the induced electric fields, indicating both directions and relative magnitudes (as in Fig. 33-6). (b) For the same instant, complete part 2 of the figure by drawing the electric field of the electromagnetic wave. Also draw the induced magnetic fields, indicating both directions and relative magnitudes (as in Fig. 33-7).

33-2 ENERGY TRANSPORT AND THE POYNTING VECTOR

Learning Objectives

After reading this module, you should be able to . . .

33.13 Identify that an electromagnetic wave transports energy.
33.14 For a target, identify that an EM wave’s rate of energy transport per unit area is given by the Poynting vector \( \vec{S} \), which is related to the cross product of the electric field \( \vec{E} \) and magnetic field \( \vec{B} \).
33.15 Determine the direction of travel (and thus energy transport) of an electromagnetic wave by applying the cross product for the corresponding Poynting vector.
33.16 Calculate the instantaneous rate \( S \) of energy flow of an EM wave in terms of the instantaneous electric field magnitude \( E \).
33.17 For the electric field component of an electromagnetic wave, relate the rms value \( E_{\text{rms}} \) to the amplitude \( E_m \).
33.18 Identify an EM wave’s intensity \( I \) in terms of energy transport.
33.19 Apply the relationships between an EM wave’s intensity \( I \) and the electric field’s rms value \( E_{\text{rms}} \) and amplitude \( E_m \).
33.20 Apply the relationship between average power \( P_{\text{avg}} \), energy transfer \( \Delta E \), and the time \( \Delta t \) taken by that transfer, and apply the relationship between the instantaneous power \( P \) and the rate of energy transfer \( dE/dt \).
33.21 Identify an isotropic point source of light.
33.22 For an isotropic point source of light, apply the relationship between the emission power \( P \), the distance \( r \) to a point of measurement, and the intensity \( I \) at that point.
33.23 In terms of energy conservation, explain why the intensity from an isotropic point source of light decreases as \( 1/r^2 \).

Key Ideas

- The rate per unit area at which energy is transported via an electromagnetic wave is given by the Poynting vector \( \vec{S} \):
  \[
  \vec{S} = \frac{1}{\mu_0} \vec{E} \times \vec{B}.
  \]

The direction of \( \vec{S} \) (and thus of the wave’s travel and the energy transport) is perpendicular to the directions of both \( \vec{E} \) and \( \vec{B} \).

- The time-averaged rate per unit area at which energy is transported is \( S_{\text{avg}} \), which is called the intensity \( I \) of the wave:
  \[
  I = \frac{1}{c \mu_0} E_{\text{rms}}^2,
  \]

in which \( E_{\text{rms}} = E_m/\sqrt{2} \).

- A point source of electromagnetic waves emits the waves isotropically—that is, with equal intensity in all directions. The intensity of the waves at distance \( r \) from a point source of power \( P \) is
  \[
  I = \frac{P_s}{4 \pi r^2}.
  \]
Energy Transport and the Poynting Vector

All sunbathers know that an electromagnetic wave can transport energy and deliver it to a body on which the wave falls. The rate of energy transport per unit area in such a wave is described by a vector \( \vec{S} \), called the **Poynting vector** after physicist John Henry Poynting (1852–1914), who first discussed its properties. This vector is defined as

\[
\vec{S} = \frac{1}{\mu_0} \vec{E} \times \vec{B} \quad \text{(Poynting vector).} \tag{33-19}
\]

Its magnitude \( S \) is related to the rate at which energy is transported by a wave across a unit area at any instant (inst):

\[
S = \left( \frac{\text{energy/time}}{\text{area}} \right)_{\text{inst}} = \left( \frac{\text{power}}{\text{area}} \right)_{\text{inst}}. \tag{33-20}
\]

From this we can see that the SI unit for \( \vec{S} \) is the watt per square meter (W/m\(^2\)).

The direction of the Poynting vector \( \vec{S} \) of an electromagnetic wave at any point gives the wave’s direction of travel and the direction of energy transport at that point.

Because \( \vec{E} \) and \( \vec{B} \) are perpendicular to each other in an electromagnetic wave, the magnitude of \( \vec{E} \times \vec{B} \) is \( EB \). Then the magnitude of \( \vec{S} \) is

\[
S = \frac{1}{\mu_0} EB, \tag{33-21}
\]

in which \( S, E, \) and \( B \) are instantaneous values. The magnitudes \( E \) and \( B \) are so closely coupled to each other that we need to deal with only one of them; we choose \( E \), largely because most instruments for detecting electromagnetic waves deal with the electric component of the wave rather than the magnetic component. Using \( B = \frac{E}{c} \) from Eq. 33-5, we can rewrite Eq. 33-21 in terms of just the electric component as

\[
S = \frac{1}{c\mu_0} E^2 \quad \text{(instantaneous energy flow rate).} \tag{33-22}
\]

**Intensity.** By substituting \( E = E_m \sin(kx - \omega t) \) into Eq. 33-22, we could obtain an equation for the energy transport rate as a function of time. More useful in practice, however, is the average energy transported over time; for that, we need to find the time-averaged value of \( S \), written \( S_{\text{avg}} \) and also called the **intensity** \( I \) of the wave. Thus from Eq. 33-20, the intensity \( I \) is

\[
I = S_{\text{avg}} = \left( \frac{\text{energy/time}}{\text{area}} \right)_{\text{avg}} = \left( \frac{\text{power}}{\text{area}} \right)_{\text{avg}}. \tag{33-23}
\]

From Eq. 33-22, we find

\[
I = S_{\text{avg}} = \frac{1}{c\mu_0} [E^2]_{\text{avg}} = \frac{1}{c\mu_0} [E_m^2 \sin^2(kx - \omega t)]_{\text{avg}}. \tag{33-24}
\]

Over a full cycle, the average value of \( \sin^2 \theta \), for any angular variable \( \theta \), is \( \frac{1}{2} \) (see Fig. 31-17). In addition, we define a new quantity \( E_{\text{rms}} \), the **root-mean-square** value of the electric field, as

\[
E_{\text{rms}} = \frac{E_m}{\sqrt{2}}. \tag{33-25}
\]
We can then rewrite Eq. 33-24 as

\[ I = \frac{1}{c \mu_0} E_{\text{rms}}^2. \]  

Because \( E = cB \) and \( c \) is such a very large number, you might conclude that the energy associated with the electric field is much greater than that associated with the magnetic field. That conclusion is incorrect; the two energies are exactly equal. To show this, we start with Eq. 25-25, which gives the energy density \( u = \frac{1}{2}e_0 E^2 \) within an electric field, and substitute \( cB \) for \( E \); then we can write

\[ u_E = \frac{1}{2}e_0 E^2 = \frac{1}{2}e_0 (cB)^2. \]

If we now substitute for \( c \) with Eq. 33-3, we get

\[ u_E = \frac{1}{2}e_0 \frac{1}{\mu_0 e_0} B^2 = \frac{B^2}{2\mu_0}. \]

However, Eq. 30-55 tells us that \( B^2/2\mu_0 \) is the energy density \( u_B \) of a magnetic field \( \vec{B} \); so we see that \( u_E = u_B \) everywhere along an electromagnetic wave.

**Variation of Intensity with Distance**

How intensity varies with distance from a real source of electromagnetic radiation is often complex—especially when the source (like a searchlight at a movie premier) beams the radiation in a particular direction. However, in some situations we can assume that the source is a point source that emits the light isotropically—that is, with equal intensity in all directions. The spherical wavefronts spreading from such an isotropic point source \( S \) at a particular instant are shown in cross section in Fig. 33-8.

Let us assume that the energy of the waves is conserved as they spread from this source. Let us also center an imaginary sphere of radius \( r \) on the source, as shown in Fig. 33-8. All the energy emitted by the source must pass through the sphere. Thus, the rate at which energy passes through the sphere via the radiation must equal the rate at which energy is emitted by the source—that is, the source power \( P_s \). The intensity \( I \) (power per unit area) measured at the sphere must then be, from Eq. 33-23,

\[ I = \frac{\text{power}}{\text{area}} = \frac{P_s}{4\pi r^2}, \]  

where \( 4\pi r^2 \) is the area of the sphere. Equation 33-27 tells us that the intensity of the electromagnetic radiation from an isotropic point source decreases with the square of the distance \( r \) from the source.

**Checkpoint 2**

The figure here gives the electric field of an electromagnetic wave at a certain point and a certain instant. The wave is transporting energy in the negative \( z \) direction. What is the direction of the magnetic field of the wave at that point and instant?

**Sample Problem 33.01** Light wave: rms values of the electric and magnetic fields

When you look at the North Star (Polaris), you intercept light from a star at a distance of 431 ly and emitting energy at a rate of \( 2.2 \times 10^3 \) times that of our Sun \( (P_{\text{sun}} = 3.90 \times 10^{26} \text{ W}) \). Neglecting any atmospheric absorption, find the rms values of the electric and magnetic fields when the starlight reaches you.
**33-3 RADIATION PRESSURE**

**Learning Objectives**

*33.24* Distinguish between force and pressure.

*33.25* Identify that an electromagnetic wave transports momentum and can exert a force and a pressure on a target.

*33.26* For a uniform electromagnetic beam that is perpendicular to a target area, apply the relationships between that area, the wave’s intensity, and the force on the target, for both total absorption and total backward reflection.

*33.27* For a uniform electromagnetic beam that is perpendicular to a target area, apply the relationships between the wave’s intensity and the pressure on the target, for both total absorption and total backward reflection.

**Key Ideas**

- When a surface intercepts electromagnetic radiation, a force and a pressure are exerted on the surface.
- If the radiation is totally absorbed by the surface, the force is
  \[ F = \frac{IA}{c} \]  
  (total absorption),
  
  in which \( I \) is the intensity of the radiation and \( A \) is the area of the surface perpendicular to the path of the radiation.
- If the radiation is totally reflected back along its original path, the force is
  \[ F = \frac{2IA}{c} \]  
  (total reflection back along path).
- The radiation pressure \( p_r \) is the force per unit area:
  \[ p_r = \frac{I}{c} \]  
  (total absorption)
  
  and
  \[ p_r = \frac{2I}{c} \]  
  (total reflection back along path).

**Radiation Pressure**

Electromagnetic waves have linear momentum and thus can exert a pressure on an object when shining on it. However, the pressure must be very small because, for example, you do not feel a punch during a camera flash.

By substituting \( I = (2.2 \times 10^3)(3.90 \times 10^{26}) \) W, \( r = 431 \) ly = \( 4.08 \times 10^{18} \) m, and values for the constants, we find

\[ E_{\text{rms}} = 1.24 \times 10^{-3} \text{ V/m} \approx 1.2 \text{ mV/m}. \]  

**Magnetic field:** From Eq. 33-5, we write

\[ B_{\text{rms}} = \frac{E_{\text{rms}}}{c} = \frac{1.24 \times 10^{-3} \text{ V/m}}{3.00 \times 10^8 \text{ m/s}} \]

\[ = 4.1 \times 10^{-12} \text{ T} = 4.1 \text{ pT}. \]

**Cannot compare the fields:** Note that \( E_{\text{rms}} \) (= 1.2 mV/m) is small as judged by ordinary laboratory standards, but \( B_{\text{rms}} \) (= 4.1 pT) is quite small. This difference helps to explain why most instruments used for the detection and measurement of electromagnetic waves are designed to respond to the electric component. It is wrong, however, to say that the electric component of an electromagnetic wave is “stronger” than the magnetic component. You cannot compare quantities that are measured in different units. However, these electric and magnetic components are on an equal basis because their average energies, which can be compared, are equal.

Additional examples, video, and practice available at WileyPLUS
To find an expression for the pressure, let us shine a beam of electromagnetic radiation—light, for example—on an object for a time interval $\Delta t$. Further, let us assume that the object is free to move and that the radiation is entirely absorbed (taken up) by the object. This means that during the interval $\Delta t$, the object gains an energy $\Delta U$ from the radiation. Maxwell showed that the object also gains linear momentum. The magnitude $\Delta p$ of the momentum change of the object is related to the energy change $\Delta U$ by

$$\Delta p = \frac{\Delta U}{c} \quad \text{(total absorption)},$$  
(33-28)

where $c$ is the speed of light. The direction of the momentum change of the object is the direction of the incident (incoming) beam that the object absorbs.

Instead of being absorbed, the radiation can be reflected by the object; that is, the radiation can be sent off in a new direction as if it bounced off the object. If the radiation is entirely reflected back along its original path, the magnitude of the momentum change of the object is twice that given above, or

$$\Delta p = \frac{2 \Delta U}{c} \quad \text{(total reflection back along path).}$$  
(33-29)

In the same way, an object undergoes twice as much momentum change when a perfectly elastic tennis ball is bounced from it as when it is struck by a perfectly inelastic ball (a lump of wet putty, say) of the same mass and velocity. If the incident radiation is partly absorbed and partly reflected, the momentum change of the object is between $\Delta U/c$ and $2 \Delta U/c$.

**Force.** From Newton’s second law in its linear momentum form (Module 9-3), we know that a change in momentum is related to a force by

$$F = \frac{\Delta p}{\Delta t}.$$  
(33-30)

To find expressions for the force exerted by radiation in terms of the intensity $I$ of the radiation, we first note that intensity is

$$I = \frac{\text{power}}{\text{area}} = \frac{\text{energy/time}}{\text{area}}.$$  

Next, suppose that a flat surface of area $A$, perpendicular to the path of the radiation, intercepts the radiation. In time interval $\Delta t$, the energy intercepted by area $A$ is

$$\Delta U = IA \Delta t.$$  
(33-31)

If the energy is completely absorbed, then Eq. 33-28 tells us that $\Delta p = IA \Delta t/c$, and, from Eq. 33-30, the magnitude of the force on the area $A$ is

$$F = \frac{IA}{c} \quad \text{(total absorption)}.$$  
(33-32)

Similarly, if the radiation is totally reflected back along its original path, Eq. 33-29 tells us that $\Delta p = 2IA \Delta t/c$ and, from Eq. 33-30,

$$F = \frac{2IA}{c} \quad \text{(total reflection back along path).}$$  
(33-33)

If the radiation is partly absorbed and partly reflected, the magnitude of the force on area $A$ is between the values of $IA/c$ and $2IA/c$.

**Pressure.** The force per unit area on an object due to radiation is the radiation pressure $p_r$. We can find it for the situations of Eqs. 33-32 and 33-33 by dividing both sides of each equation by $A$. We obtain

$$p_r = \frac{I}{c} \quad \text{(total absorption)}.$$  
(33-34)
and \[ p_r = \frac{2I}{c} \] (total reflection back along path). (33-35)

Be careful not to confuse the symbol \( p_r \) for radiation pressure with the symbol \( p \) for momentum. Just as with fluid pressure in Chapter 14, the SI unit of radiation pressure is the newton per square meter (N/m\(^2\)), which is called the pascal (Pa).

The development of laser technology has permitted researchers to achieve radiation pressures much greater than, say, that due to a camera flashlamp. This comes about because a beam of laser light—unlike a beam of light from a small lamp filament—can be focused to a tiny spot. This permits the delivery of great amounts of energy to small objects placed at that spot.

**Checkpoint 3**

Light of uniform intensity shines perpendicularly on a totally absorbing surface, fully illuminating the surface. If the area of the surface is decreased, do (a) the radiation pressure and (b) the radiation force on the surface increase, decrease, or stay the same?

---

### 33-4 POLARIZATION

**Learning Objectives**

After reading this module, you should be able to . . .

- **33.28** Distinguish between polarized light and unpolarized light.
- **33.29** For a light beam headed toward you, sketch representations of polarized light and unpolarized light.
- **33.30** When a beam is sent into a polarizing sheet, explain the function of the sheet in terms of its polarizing direction (or axis) and the electric field component that is absorbed and the component that is transmitted.
- **33.31** For light that emerges from a polarizing sheet, identify its polarization relative to the sheet’s polarizing direction.
- **33.32** For a light beam incident perpendicularly on a polarizing sheet, apply the one-half rule and the cosine-squared rule, distinguishing their uses.
- **33.33** Distinguish between a polarizer and an analyzer.
- **33.34** Explain what is meant if two sheets are crossed.
- **33.35** When a beam is sent into a system of polarizing sheets, work through the sheets one by one, finding the transmitted intensity and polarization.

**Key Ideas**

- Electromagnetic waves are polarized if their electric field vectors are all in a single plane, called the plane of oscillation. Light waves from common sources are not polarized; that is, they are unpolarized, or polarized randomly.
- When a polarizing sheet is placed in the path of light, only electric field components of the light parallel to the sheet’s polarizing direction are transmitted by the sheet; components perpendicular to the polarizing direction are absorbed. The light that emerges from a polarizing sheet is polarized parallel to the polarizing direction of the sheet.
- If the original light is initially unpolarized, the transmitted intensity \( I \) is half the original intensity \( I_0 \):
  \[ I = \frac{1}{2} I_0. \]
- If the original light is initially polarized, the transmitted intensity depends on the angle \( \theta \) between the polarization direction of the original light and the polarizing direction of the sheet:
  \[ I = I_0 \cos^2 \theta. \]

**Polarization**

VHF (very high frequency) television antennas in England are oriented vertically, but those in North America are horizontal. The difference is due to the direction of oscillation of the electromagnetic waves carrying the TV signal. In England, the transmitting equipment is designed to produce waves that are polarized vertically; that is, their electric field oscillates vertically. Thus, for the
ELECTROMAGNETIC WAVES

**Figure 33-9** (a) The plane of oscillation of a polarized electromagnetic wave. (b) To represent the polarization, we view the plane of oscillation head-on and indicate the directions of the oscillating electric field with a double arrow.

electric field of the incident television waves to drive a current along an antenna (and provide a signal to a television set), the antenna must be vertical. In North America, the waves are polarized horizontally.

Figure 33-9a shows an electromagnetic wave with its electric field oscillating parallel to the vertical y axis. The plane containing the \( \vec{E} \) vectors is called the **plane of oscillation** of the wave (hence, the wave is said to be *plane-polarized* in the y direction). We can represent the wave’s **polarization** (state of being polarized) by showing the directions of the electric field oscillations in a head-on view of the plane of oscillation, as in Fig. 33-9b. The vertical double arrow in that figure indicates that as the wave travels past us, its electric field oscillates vertically—it continuously changes between being directed up and down the y axis.

### Polarized Light

The electromagnetic waves emitted by a television station all have the same polarization, but the electromagnetic waves emitted by any common source of light (such as the Sun or a bulb) are **polarized randomly**, or **unpolarized** (the two terms mean the same thing). That is, the electric field at any given point is always perpendicular to the direction of travel of the waves but changes directions randomly. Thus, if we try to represent a head-on view of the oscillations over some time period, we do not have a simple drawing with a single double arrow like that of Fig. 33-9b; instead we have a mess of double arrows like that in Fig. 33-10a.

In principle, we can simplify the mess by resolving each electric field of Fig. 33-10a into y and z components. Then as the wave travels past us, the net y component oscillates parallel to the y axis and the net z component oscillates parallel to the z axis. We can then represent the unpolarized light with a pair of double arrows as shown in Fig. 33-10b. The double arrow along the y axis represents the oscillations of the net y component of the electric field. The double arrow along the z axis represents the oscillations of the net z component of the electric field. In doing all this, we effectively change unpolarized light into the superposition of two polarized waves whose planes of oscillation are perpendicular to each other—one plane contains the y axis and the other contains the z axis. One reason to make this change is that drawing Fig. 33-10b is a lot easier than drawing Fig. 33-10a.

We can draw similar figures to represent light that is **partially polarized** (its field oscillations are not completely random as in Fig. 33-10a, nor are they parallel to a single axis as in Fig. 33-9b). For this situation, we draw one of the double arrows in a perpendicular pair of double arrows longer than the other one.

**Polarizing Direction.** We can transform unpolarized visible light into polarized light by sending it through a **polarizing sheet**, as is shown in Fig. 33-11. Such sheets, commercially known as Polaroids or Polaroid filters, were invented in 1932 by Edwin Land while he was an undergraduate student. A polarizing sheet consists of certain long molecules embedded in plastic. When the sheet is manu-
factured, it is stretched to align the molecules in parallel rows, like rows in a plowed field. When light is then sent through the sheet, electric field components along one direction pass through the sheet, while components perpendicular to that direction are absorbed by the molecules and disappear.

We shall not dwell on the molecules but, instead, shall assign to the sheet a polarizing direction, along which electric field components are passed:

An electric field component parallel to the polarizing direction is passed (transmitted) by a polarizing sheet; a component perpendicular to it is absorbed.

Thus, the electric field of the light emerging from the sheet consists of only the components that are parallel to the polarizing direction of the sheet; hence the light is polarized in that direction. In Fig. 33-11, the vertical electric field components are transmitted by the sheet; the horizontal components are absorbed. The transmitted waves are then vertically polarized.

**Intensity of Transmitted Polarized Light**

We now consider the intensity of light transmitted by a polarizing sheet. We start with unpolarized light, whose electric field oscillations we can resolve into $y$ and $z$ components as represented in Fig. 33-10b. Further, we can arrange for the $y$ axis to be parallel to the polarizing direction of the sheet. Then only the $y$ components of the light’s electric field are passed by the sheet; the $z$ components are absorbed. As suggested by Fig. 33-10b, if the original waves are randomly oriented, the sum of the $y$ components and the sum of the $z$ components are equal. When the $z$ components are absorbed, half the intensity $I_0$ of the original light is lost. The intensity $I$ of the emerging polarized light is then

$$I = \frac{1}{2} I_0 \quad \text{(one-half rule).} \quad (33-36)$$

Let us call this the one-half rule; we can use it only when the light reaching a polarizing sheet is unpolarized.

Suppose now that the light reaching a polarizing sheet is already polarized. Figure 33-12 shows a polarizing sheet in the plane of the page and the electric field $\vec{E}$ of such a polarized light wave traveling toward the sheet (and thus prior to any absorption). We can resolve $\vec{E}$ into two components relative to the polarizing direction of the sheet: parallel component $E_y$ is transmitted by the sheet, and perpendicular component $E_z$ is absorbed. Since $\theta$ is the angle between $\vec{E}$ and the polarizing direction of the sheet, the transmitted parallel component is

$$E_y = E \cos \theta. \quad (33-37)$$

Recall that the intensity of an electromagnetic wave (such as our light wave) is proportional to the square of the electric field’s magnitude (Eq. 33-26, $I = E_{\text{rms}}^2/c\mu_0$). In our present case then, the intensity $I$ of the emerging wave is proportional to $E_y^2$ and the intensity $I_0$ of the original wave is proportional to $E^2$. Hence, from Eq. 33-37 we can write $I/I_0 = \cos^2 \theta$, or

$$I = I_0 \cos^2 \theta \quad \text{(cosine-squared rule).} \quad (33-38)$$

Let us call this the cosine-squared rule; we can use it only when the light reaching a polarizing sheet is already polarized. Then the transmitted intensity $I$ is a maximum and is equal to the original intensity $I_0$ when the original wave is polarized parallel to the polarizing direction of the sheet (when $\theta$ in Eq. 33-38 is 0° or 180°). The transmitted intensity is zero when the original wave is polarized perpendicular to the polarizing direction of the sheet (when $\theta$ is 90°).
Two Polarizing Sheets. Figure 33-13 shows an arrangement in which initially unpolarized light is sent through two polarizing sheets $P_1$ and $P_2$. (Often, the first sheet is called the polarizer, and the second the analyzer.) Because the polarizing direction of $P_1$ is vertical, the light transmitted by $P_1$ to $P_2$ is polarized vertically. If the polarizing direction of $P_2$ is also vertical, then all the light transmitted by $P_1$ is transmitted by $P_2$. If the polarizing direction of $P_2$ is horizontal, none of the light transmitted by $P_1$ is transmitted by $P_2$. We reach the same conclusions by considering only the relative orientations of the two sheets: If their polarizing directions are parallel, all the light passed by the first sheet is passed by the second sheet (Fig. 33-14a). If those directions are perpendicular (the sheets are said to be crossed), no light is passed by the second sheet (Fig. 33-14b). Finally, if the two polarizing directions of Fig. 33-13 make an angle between $0^\circ$ and $90^\circ$, some of the light transmitted by $P_1$ will be transmitted by $P_2$, as set by Eq. 33-38.

Other Means. Light can be polarized by means other than polarizing sheets, such as by reflection (discussed in Module 33-7) and by scattering from atoms or molecules. In scattering, light that is intercepted by an object, such as a molecule, is sent off in many, perhaps random, directions. An example is the scattering of sunlight by molecules in the atmosphere, which gives the sky its general glow.

Although direct sunlight is unpolarized, light from much of the sky is at least partially polarized by such scattering. Bees use the polarization of sky light in navigating to and from their hives. Similarly, the Vikings used it to navigate across the North Sea when the daytime Sun was below the horizon (because of the high latitude of the North Sea). These early seafarers had discovered certain crystals (now called cordierite) that changed color when rotated in polarized light. By looking at the sky through such a crystal while rotating it about their line of sight, they could locate the hidden Sun and thus determine which way was south.

Checkpoint 4

The figure shows four pairs of polarizing sheets, seen face-on. Each pair is mounted in the path of initially unpolarized light. The polarizing direction of each sheet (indicated by the dashed line) is referenced to either a horizontal $x$ axis or a vertical $y$ axis. Rank the pairs according to the fraction of the initial intensity that they pass, greatest first.
Sample Problem 33.02  Polarization and intensity with three polarizing sheets

Figure 33-15a, drawn in perspective, shows a system of three polarizing sheets in the path of initially unpolarized light. The polarizing direction of the first sheet is parallel to the y axis, that of the second sheet is at an angle of 60° counterclockwise from the y axis, and that of the third sheet is parallel to the x axis. What fraction of the initial intensity $I_0$ of the light emerges from the three-sheet system, and in which direction is that emerging light polarized?

**KEY IDEAS**

1. We work through the system sheet by sheet, from the first one encountered by the light to the last one.

2. To find the intensity transmitted by any sheet, we apply either the one-half rule or the cosine-squared rule, depending on whether the light reaching the sheet is unpolarized or already polarized.

3. The light that is transmitted by a polarizing sheet is always polarized parallel to the polarizing direction of the sheet.

**First sheet:** The original light wave is represented in Fig. 33-15b, using the head-on, double-arrow representation of Fig. 33-10b. Because the light is initially unpolarized, the intensity $I_1$ of the light transmitted by the first sheet is given by the one-half rule (Eq. 33-36): 

$$I_1 = \frac{1}{2} I_0.$$ 

**Intensity rules:**

If the incident light is unpolarized, use the one-half rule:

$$I_{\text{emerge}} = 0.5 I_{\text{incident}}.$$ 

If the incident light is already polarized, use the cosine-squared rule:

$$I_{\text{emerge}} = I_{\text{incident}} (\cos \theta)^2,$$

but be sure to insert the angle between the polarization of the incident light and the polarization axis of the sheet.

---

*Figure 33-15*  (a) Initially unpolarized light of intensity $I_0$ is sent into a system of three polarizing sheets. The intensities $I_1$, $I_2$, and $I_3$ of the light transmitted by the sheets are labeled. Shown also are the polarizations, from head-on views, of (b) the initial light and the light transmitted by (c) the first sheet, (d) the second sheet, and (e) the third sheet.
Because the polarizing direction of the first sheet is parallel to the y axis, the polarization of the light transmitted by it is also, as shown in the head-on view of Fig. 33-15c.

**Second sheet:** Because the light reaching the second sheet is polarized, the intensity $I_2$ of the light transmitted by that sheet is given by the cosine-squared rule (Eq. 33-38). The angle $\theta$ in the rule is the angle between the polarization direction of the entering light (parallel to the y axis) and the polarization direction of the second sheet ($60^\circ$ counterclockwise from the y axis), and so $\theta$ is $60^\circ$. (The larger angle between the two directions, namely $120^\circ$, can also be used.) We have

$$I_2 = I_1 \cos^2 60^\circ.$$ 

The polarization of this transmitted light is parallel to the polarization direction of the sheet transmitting it—that is, $60^\circ$ counterclockwise from the y axis, as shown in the head-on view of Fig. 33-15d.

**Third sheet:** Because the light reaching the third sheet is polarized, the intensity $I_3$ of the light transmitted by that sheet is given by the cosine-squared rule. The angle $\theta$ is now the angle between the polarization direction of the entering light (Fig. 33-15d) and the polarization direction of the third sheet (parallel to the x axis), and so $\theta = 30^\circ$. Thus,

$$I_3 = I_2 \cos 30^\circ.$$ 

This final transmitted light is polarized parallel to the x axis (Fig. 33-15e). We find its intensity by substituting first for $I_2$ and then for $I_1$ in the equation above:

$$I_3 = I_2 \cos^2 30^\circ = (I_1 \cos^2 60^\circ) \cos^2 30^\circ = (\frac{1}{2}I_0) \cos^2 60^\circ \cos^2 30^\circ = 0.094I_0.$$ 

Thus,

$$\frac{I_3}{I_0} = 0.094.$$ 

That is to say, $9.4\%$ of the initial intensity emerges from the three-sheet system. (If we now remove the second sheet, what fraction of the initial intensity emerges from the system?)

### 33-5 REFLECTION AND REFRACTION

#### Learning Objectives

*After reading this module, you should be able to . . .*

33.36 With a sketch, show the reflection of a light ray from an interface and identify the incident ray, the reflected ray, the normal, the angle of incidence, and the angle of reflection.

33.37 For a reflection, relate the angle of incidence and the angle of reflection.

33.38 With a sketch, show the refraction of a light ray at an interface and identify the incident ray, the refracted ray, the normal on each side of the interface, the angle of incidence, and the angle of refraction.

33.39 For refraction of light, apply Snell’s law to relate the index of refraction and the angle of the ray on one side of the interface to those quantities on the other side.

33.40 In a sketch and using a line along the undeflected direction, show the refraction of light from one material into a second material that has a greater index, a smaller index, and the same index, and, for each situation, describe the refraction in terms of the ray being bent toward the normal, away from the normal, or not at all.

33.41 Identify that refraction occurs only at an interface and not in the interior of a material.

33.42 Identify chromatic dispersion.

33.43 For a beam of red and blue light (or other colors) refracting at an interface, identify which color has the greater bending and which has the greater angle of refraction when they enter a material with a lower index than the initial material and a greater index.

33.44 Describe how the primary and secondary rainbows are formed and explain why they are circular arcs.

#### Key Ideas

- Geometrical optics is an approximate treatment of light in which light waves are represented as straight-line rays.
- When a light ray encounters a boundary between two transparent media, a reflected ray and a refracted ray generally appear. Both rays remain in the plane of incidence. The angle of reflection is equal to the angle of incidence, and the angle of refraction is related to the angle of incidence by Snell’s law,

$$n_2 \sin \theta_2 = n_1 \sin \theta_1 \quad \text{(refraction)},$$

where $n_1$ and $n_2$ are the indexes of refraction of the media in which the incident and refracted rays travel.
Reflection and Refraction

Although a light wave spreads as it moves away from its source, we can often approximate its travel as being in a straight line; we did so for the light wave in Fig. 33-5a. The study of the properties of light waves under that approximation is called geometrical optics. For the rest of this chapter and all of Chapter 34, we shall discuss the geometrical optics of visible light.

The photograph in Fig. 33-16a shows an example of light waves traveling in approximately straight lines. A narrow beam of light (the incident beam), angled downward from the left and traveling through air, encounters a plane (flat) water surface. Part of the light is reflected by the surface, forming a beam directed upward toward the right, traveling as if the original beam had bounced from the surface. The rest of the light travels through the surface and into the water, forming a beam directed downward to the right. Because light can travel through it, the water is said to be transparent; that is, we can see through it. (In this chapter we shall consider only transparent materials and not opaque materials, through which light cannot travel.)

The travel of light through a surface (or interface) that separates two media is called refraction, and the light is said to be refracted. Unless an incident beam of light is perpendicular to the surface, refraction changes the light’s direction of travel. For this reason, the beam is said to be “bent” by the refraction. Note in Fig. 33-16a that the bending occurs only at the surface; within the water, the light travels in a straight line.

In Figure 33-16b, the beams of light in the photograph are represented with an incident ray, a reflected ray, and a refracted ray (and wavefronts). Each ray is oriented with respect to a line, called the normal, that is perpendicular to the surface at the point of reflection and refraction. In Fig. 33-16b, the angle of incidence is \( \theta_1 \), the angle of reflection is \( \theta'_1 \), and the angle of refraction is \( \theta_2 \), all measured relative to the normal. The plane containing the incident ray and the normal is the plane of incidence, which is in the plane of the page in Fig. 33-16b.

Experiment shows that reflection and refraction are governed by two laws:

**Law of reflection:** A reflected ray lies in the plane of incidence and has an angle of reflection equal to the angle of incidence (both relative to the normal). In Fig. 33-16b, this means that

\[
\theta'_1 = \theta_1 \quad \text{(reflection).} \tag{33-39}
\]

(We shall now usually drop the prime on the angle of reflection.)

---

**Figure 33-16** (a) A photograph showing an incident beam of light reflected and refracted by a horizontal water surface. (b) A ray representation of (a). The angles of incidence \( (\theta_1) \), reflection \( (\theta'_1) \), and refraction \( (\theta_2) \) are marked.
Law of refraction: A refracted ray lies in the plane of incidence and has an angle of refraction $\theta_2$ that is related to the angle of incidence $\theta_1$ by

$$n_2 \sin \theta_2 = n_1 \sin \theta_1 \quad \text{(reftaction).} \tag{33-40}$$

Here each of the symbols $n_1$ and $n_2$ is a dimensionless constant, called the index of refraction, that is associated with a medium involved in the refraction. We derive this equation, called Snell’s law, in Chapter 35. As we shall discuss there, the index of refraction of a medium is equal to $c/v$, where $v$ is the speed of light in that medium and $c$ is its speed in vacuum.

Table 33-1 gives the indexes of refraction of vacuum and some common substances. For vacuum, $n$ is defined to be exactly 1; for air, $n$ is very close to 1.0 (an approximation we shall often make). Nothing has an index of refraction below 1.

We can rearrange Eq. 33-40 as

$$\sin \theta_2 = \frac{n_1}{n_2} \sin \theta_1 \quad \text{(33-41)}$$

to compare the angle of refraction $\theta_2$ with the angle of incidence $\theta_1$. We can then see that the relative value of $\theta_2$ depends on the relative values of $n_2$ and $n_1$:

1. If $n_2$ is equal to $n_1$, then $\theta_2$ is equal to $\theta_1$ and refraction does not bend the light beam, which continues in the undeflected direction, as in Fig. 33-17a.

2. If the next index is greater, the ray is bent toward the normal.

3. If the next index is less, the ray is bent away from the normal.

![Figure 33-17](image-url) Refraction of light traveling from a medium with an index of refraction $n_1$ into a medium with an index of refraction $n_2$. (a) The beam does not bend when $n_2 = n_1$; the refracted light then travels in the undeflected direction (the dotted line), which is the same as the direction of the incident beam. The beam bends (b) toward the normal when $n_2 > n_1$ and (c) away from the normal when $n_2 < n_1$.

$^a$For a wavelength of 589 nm (yellow sodium light).

$^b$STP means “standard temperature (0°C) and pressure (1 atm).”
2. If \( n_2 \) is greater than \( n_1 \), then \( \theta_2 \) is less than \( \theta_1 \). In this case, refraction bends the light beam away from the undeflected direction and toward the normal, as in Fig. 33-17b.

3. If \( n_2 \) is less than \( n_1 \), then \( \theta_2 \) is greater than \( \theta_1 \). In this case, refraction bends the light beam away from the undeflected direction and away from the normal, as in Fig. 33-17c.

Refraction cannot bend a beam so much that the refracted ray is on the same side of the normal as the incident ray.

**Chromatic Dispersion**

The index of refraction \( n \) encountered by light in any medium except vacuum depends on the wavelength of the light. The dependence of \( n \) on wavelength implies that when a light beam consists of rays of different wavelengths, the rays will be refracted at different angles by a surface; that is, the light will be spread out by the refraction. This spreading of light is called **chromatic dispersion**, in which “chromatic” refers to the colors associated with the individual wavelengths and “dispersion” refers to the spreading of the light according to its wavelengths or colors. The refractions of Figs. 33-16 and 33-17 do not show chromatic dispersion because the beams are **monochromatic** (of a single wavelength or color).

Generally, the index of refraction of a given medium is greater for a shorter wavelength (corresponding to, say, blue light) than for a longer wavelength (say, red light). As an example, Fig. 33-18 shows how the index of refraction of fused quartz depends on the wavelength of light. Such dependence means that when a beam made up of waves of both blue and red light is refracted through a surface, such as from air into quartz or vice versa, the blue component (the ray corresponding to the wave of blue light) bends more than the red component.

A beam of white light consists of components of all (or nearly all) the colors in the visible spectrum with approximately uniform intensities. When you see such a beam, you perceive white rather than the individual colors. In Fig. 33-19a, a beam of white light in air is incident on a glass surface. (Because the pages of this book are white, a beam of white light is represented with a gray ray here. Also, a beam of monochromatic light is generally represented with a red ray.) Of the refracted light in Fig. 33-19a, only the red and blue components are shown. Because the blue component is bent more than the red component, the angle of refraction \( \theta_{2b} \) for the blue component is smaller than the angle of refraction \( \theta_{2r} \) for the red component. (Remember, angles are measured relative to the normal.) In Fig. 33-19b, a ray of white light in glass is incident on a glass–air interface. Again, the blue component is bent more than the red component, but now \( \theta_{2b} \) is greater than \( \theta_{2r} \).

**Figure 33-18** The index of refraction as a function of wavelength for fused quartz. The graph indicates that a beam of short-wavelength light, for which the index of refraction is higher, is bent more upon entering or leaving quartz than a beam of long-wavelength light.
To increase the color separation, we can use a solid glass prism with a triangular cross section, as in Fig. 33-20a. The dispersion at the first surface (on the left in Figs. 33-20a, b) is then enhanced by the dispersion at the second surface.

**Rainbows**

The most charming example of chromatic dispersion is a rainbow. When sunlight (which consists of all visible colors) is intercepted by a falling raindrop, some of the light refracts into the drop, reflects once from the drop’s inner surface, and then refracts out of the drop. Figure 33-21a shows the situation when the Sun is on the horizon at the left (and thus when the rays of sunlight are horizontal). The first refraction separates the sunlight into its component colors, and the second refraction increases the separation. (Only the red and blue rays are shown in the figure.) If many falling drops are brightly illuminated, you can see the separated colors they produce when the drops are at an angle of 42° from the direction of the *antisolar point* A, the point directly opposite the Sun in your view.

To locate the drops, face away from the Sun and point both arms directly away from the Sun, toward the shadow of your head. Then move your right arm directly up, directly rightward, or in any intermediate direction until the angle between your arms is 42°. If illuminated drops happen to be in the direction of your right arm, you see color in that direction.

Because any drop at an angle of 42° in any direction from A can contribute to the rainbow, the rainbow is always a 42° circular arc around A (Fig. 33-21b) and the top of a rainbow is never more than 42° above the horizon. When the Sun is above the horizon, the direction of A is below the horizon, and only a shorter, lower rainbow arc is possible (Fig. 33-21c).

Because rainbows formed in this way involve one reflection of light inside each drop, they are often called *primary rainbows*. A *secondary rainbow* involves two reflections inside a drop, as shown in Fig. 33-21d. Colors appear in the secondary rainbow at an angle of 52° from the direction of A. A secondary rainbow
is wider and dimmer than a primary rainbow and thus is more difficult to see. Also, the order of colors in a secondary rainbow is reversed from the order in a primary rainbow, as you can see by comparing parts a and d of Fig. 33-21.

Rainbows involving three or four reflections occur in the direction of the Sun and cannot be seen against the glare of sunshine in that part of the sky but have been photographed with special techniques.

Checkpoint 5
Which of the three drawings here (if any) show physically possible refraction?

Sample Problem 33.03 Reflection and refraction of a monochromatic beam

(a) In Fig. 33-22a, a beam of monochromatic light reflects and refracts at point A on the interface between material 1 with index of refraction $n_1 = 1.33$ and material 2 with index of refraction $n_2 = 1.77$. The incident beam makes an angle of 50° with the interface. What is the angle of reflection at point A? What is the angle of refraction there?

KEY IDEAS

(1) The angle of reflection is equal to the angle of incidence, and both angles are measured relative to the normal to the surface at the point of reflection. (2) When light reaches the interface between two materials with different indexes of refraction (call them $n_1$ and $n_2$), part of the light can be refracted by the interface according to Snell’s law, Eq. 33-40:

$$n_2 \sin \theta_2 = n_1 \sin \theta_1,$$

where both angles are measured relative to the normal at the point of refraction.

Calculations: In Fig. 33-22a, the normal at point A is drawn as a dashed line through the point. Note that the angle of incidence $\theta_1$ is not the given 50° but is $90° - 50° = 40°$. Thus, the angle of reflection is

$$\theta_1' = \theta_1 = 40°.$$ (Answer)

The light that passes from material 1 into material 2 undergoes refraction at point A on the interface between the two materials. Again we measure angles between light rays and a normal, here at the point of refraction. Thus, in Fig. 33-22a, the angle of refraction is the angle marked $\theta_2$. Solving Eq. 33-42 for $\theta_2$ gives us

$$\theta_2 = \sin^{-1}\left(\frac{n_1}{n_2} \sin \theta_1\right) = \sin^{-1}\left(\frac{1.33}{1.77} \sin 40°\right)$$

$$= 28.88° \approx 29°.$$ (Answer)

This result means that the beam swings toward the normal (it was at 40° to the normal and is now at 29°). The reason is that when the light travels across the interface, it moves into a material with a greater index of refraction. Caution: Note that the beam does not swing through the normal so that it appears on the left side of Fig. 33-22a.

(b) The light that enters material 2 at point A then reaches point B on the interface between material 2 and material 3, which is air, as shown in Fig. 33-22b. The interface through B is parallel to that through A. At B, some of the light reflects and the rest enters the air. What is the angle of reflection? What is the angle of refraction into the air?

Calculations: We first need to relate one of the angles at
point B with a known angle at point A. Because the interface through point B is parallel to that through point A, the incident angle at B must be equal to the angle of reflection \( \theta_2 \), as shown in Fig. 33-22b. Then for reflection, we again use the law of reflection. Thus, the angle of reflection at B is

\[
\theta'_2 = \theta_2 = 28.88^\circ = 29^\circ. \quad \text{(Answer)}
\]

Next, the light that passes from material 2 into the air undergoes refraction at point B, with refraction angle \( \theta_3 \). Thus, we again apply Snell’s law of refraction, but this time we write Eq. 33-40 as

\[
n_3 \sin \theta_3 = n_2 \sin \theta_2.
\]

Solving for \( \theta_3 \) then leads to

\[
\theta_3 = \sin^{-1} \left( \frac{n_2}{n_3} \sin \theta_2 \right) = \sin^{-1} \left( \frac{1.77}{1.00} \sin 28.88^\circ \right)
\]

\[
= 58.75^\circ \approx 59^\circ. \quad \text{(Answer)}
\]

Thus, the beam swings away from the normal (it was at \( 29^\circ \) to the normal and is now at \( 59^\circ \)) because it moves into a material (air) with a lower index of refraction.

**Additional examples, video, and practice available at WileyPLUS**

### 33-6 TOTAL INTERNAL REFLECTION

**Learning Objectives**

*After reading this module, you should be able to ...*

33.45 With sketches, explain total internal reflection and include the angle of incidence, the critical angle, and the relative values of the indexes of refraction on the two sides of the interface.

33.46 Identify the angle of refraction for incidence at a critical angle.

33.47 For a given pair of indexes of refraction, calculate the critical angle.

**Key Idea**

- A wave encountering a boundary across which the index of refraction decreases will experience total internal reflection if the angle of incidence exceeds a critical angle \( \theta_c \), where

\[
\theta_c = \sin^{-1} \frac{n_2}{n_1} \quad \text{(critical angle)}.
\]

**Total Internal Reflection**

Figure 33-23a shows rays of monochromatic light from a point source S in glass incident on the interface between the glass and air. For ray \( a \), which is perpendicular to the interface, part of the light reflects at the interface and the rest travels through it with no change in direction.

For rays \( b \) through \( e \), which have progressively larger angles of incidence at the interface, there are also both reflection and refraction at the interface. As the angle of incidence increases, the angle of refraction increases; for ray \( e \) it is \( 90^\circ \), which means that the refracted ray points directly along the interface. The angle of incidence giving this situation is called the critical angle \( \theta_c \). For angles of incidence larger than \( \theta_c \), such as for rays \( f \) and \( g \), there is no refracted ray and all the light is reflected; this effect is called total internal reflection because all the light remains inside the glass.

To find \( \theta_c \), we use Eq. 33-40; we arbitrarily associate subscript 1 with the glass and subscript 2 with the air, and then we substitute \( \theta_c \) for \( \theta_1 \) and \( 90^\circ \) for \( \theta_2 \), which leads to

\[
n_1 \sin \theta_c = n_2 \sin 90^\circ,
\]

\[
(33-44)
\]
POLARIZATION BY REFLECTION

Learning Objectives

After reading this module, you should be able to . . .

33.48 With sketches, explain how unpolarized light can be converted to polarized light by reflection from an interface.
33.49 Identify Brewster’s angle.
33.50 Apply the relationship between Brewster’s angle and the indexes of refraction on the two sides of an interface.
33.51 Explain the function of polarizing sunglasses.

Key Idea

- A reflected wave will be fully polarized, with its $\mathbf{E}$ vectors perpendicular to the plane of incidence, if it strikes a boundary at the Brewster angle $\theta_B$, where

$$\theta_B = \tan^{-1} \frac{n_2}{n_1} \quad \text{(Brewster angle)}.$$
Polarization by Reflection

You can vary the glare you see in sunlight that has been reflected from, say, water by looking through a polarizing sheet (such as a polarizing sunglass lens) and then rotating the sheet’s polarizing axis around your line of sight. You can do so because any light that is reflected from a surface is either fully or partially polarized by the reflection.

Figure 33-25 shows a ray of unpolarized light incident on a glass surface. Let us resolve the electric field vectors of the light into two components. The perpendicular components are perpendicular to the plane of incidence and thus also to the page in Fig. 33-25; these components are represented with dots (as if we see the tips of the vectors). The parallel components are parallel to the plane of incidence and the page; they are represented with double-headed arrows. Because the light is unpolarized, these two components are of equal magnitude.

In general, the reflected light also has both components but with unequal magnitudes. This means that the reflected light is partially polarized—the electric fields oscillating along one direction have greater amplitudes than those oscillating along other directions. However, when the light is incident at a particular incident angle, called the Brewster angle \( \theta_B \), the reflected light has only perpendicular components, as shown in Fig. 33-25. The reflected light is then fully polarized perpendicular to the plane of incidence. The parallel components of the incident light do not disappear but (along with perpendicular components) refract into the glass.

**Polarizing Sunglasses.** Glass, water, and the other dielectric materials discussed in Module 25-5 can partially and fully polarize light by reflection. When you intercept sunlight reflected from such a surface, you see a bright spot (the glare) on the surface where the reflection takes place. If the surface is horizontal as in Fig. 33-25, the reflected light is partially or fully polarized horizontally. To eliminate such glare from horizontal surfaces, the lenses in polarizing sunglasses are mounted with their polarizing direction vertical.

**Brewster’s Law**

For light incident at the Brewster angle \( \theta_B \), we find experimentally that the reflected and refracted rays are perpendicular to each other. Because the reflected ray is reflected at the angle \( \theta_B \) in Fig. 33-25 and the refracted ray is at an angle \( \theta_r \), we have

\[
\theta_B + \theta_r = 90^\circ. \tag{33-46}
\]

These two angles can also be related with Eq. 33-40. Arbitrarily assigning subscript 1 in Eq. 33-40 to the material through which the incident and reflected rays travel, we have, from that equation,

\[
n_1 \sin \theta_B = n_2 \sin \theta_r. \tag{33-47}
\]

Combining these equations leads to

\[
n_1 \sin \theta_B = n_2 \sin(90^\circ - \theta_B) = n_2 \cos \theta_B, \tag{33-48}
\]

which gives us

\[
\theta_B = \tan^{-1} \frac{n_2}{n_1} \quad \text{(Brewster angle).} \tag{33-49}
\]

(Note carefully that the subscripts in Eq. 33-49 are not arbitrary because of our decision as to their meanings.) If the incident and reflected rays travel in air, we can approximate \( n_1 \) as unity and let \( n \) represent \( n_2 \) in order to write Eq. 33-49 as

\[
\theta_B = \tan^{-1} n \quad \text{(Brewster’s law).} \tag{33-50}
\]

This simplified version of Eq. 33-49 is known as Brewster’s law. Like \( \theta_B \), it is named after Sir David Brewster, who found both experimentally in 1812.
Electromagnetic Waves  An electromagnetic wave consists of oscillating electric and magnetic fields. The various possible frequencies of electromagnetic waves form a spectrum, a small part of which is visible light. An electromagnetic wave traveling along an x axis has an electric field \( \vec{E} \) and a magnetic field \( \vec{B} \) with magnitudes that depend on \( x \) and \( t \):

\[
E = E_0 \sin(kx - \omega t)
\]

and

\[
B = B_0 \sin(kx - \omega t),
\]

(33-1, 33-2)

where \( E_0 \) and \( B_0 \) are the amplitudes of \( \vec{E} \) and \( \vec{B} \). The oscillating electric field induces the magnetic field, and the oscillating magnetic field induces the electric field. The speed of any electromagnetic wave in vacuum is \( c \), which can be written as

\[
c = \frac{E}{B} = \frac{1}{\sqrt{\mu_0 \varepsilon_0}},
\]

(33-5, 33-3)

where \( E \) and \( B \) are the simultaneous (but nonzero) magnitudes of the two fields.

Energy Flow  The rate per unit area at which energy is transported via an electromagnetic wave is given by the Poynting vector \( \vec{S} \):

\[
\vec{S} = \frac{1}{\mu_0} \vec{E} \times \vec{B}.
\]

(33-19)

The direction of \( \vec{S} \) (and thus of the wave’s travel and the energy transport) is perpendicular to the directions of both \( \vec{E} \) and \( \vec{B} \). The time-averaged rate per unit area at which energy is transported is \( S_{\text{avg}} \), which is called the intensity \( I \) of the wave:

\[
I = \frac{1}{\mu_0} E_{\text{avg}}^2.
\]

(33-26)

in which \( E_{\text{avg}} = E_0/\sqrt{2} \). A point source of electromagnetic waves emits the waves isotropically — that is, with equal intensity in all directions. The intensity of the waves at distance \( r \) from a point source of power \( P \) is

\[
I = \frac{P}{4\pi r^2}.
\]

(33-27)

Radiation Pressure  When a surface intercepts electromagnetic radiation, a force and a pressure are exerted on the surface. If the radiation is totally absorbed by the surface, the force is

\[
F = \frac{IA}{c} \quad \text{(total absorption)},
\]

(33-32)

in which \( I \) is the intensity of the radiation and \( A \) is the area of the surface perpendicular to the path of the radiation. If the radiation is totally reflected back along its original path, the force is

\[
F = \frac{2IA}{c} \quad \text{(total reflection back along path)}.
\]

(33-33)

The radiation pressure \( p_r \) is the force per unit area:

\[
p_r = \frac{I}{c} \quad \text{(total absorption)}
\]

(33-34) and

\[
p_r = \frac{2I}{c} \quad \text{(total reflection back along path)}.
\]

(33-35)

Polarization  Electromagnetic waves are polarized if their electric field vectors are all in a single plane, called the plane of oscillation. From a head-on view, the field vectors oscillate parallel to a single axis perpendicular to the path taken by the waves. Light waves from common sources are not polarized; that is, they are unpolarized, or polarized randomly. From a head-on view, the vectors oscillate parallel to every possible axis that is perpendicular to the path taken by the waves.

Polarizing Sheets  When a polarizing sheet is placed in the path of light, only electric field components of the light parallel to the sheet’s polarizing direction are transmitted by the sheet; components perpendicular to the polarizing direction are absorbed. The light that emerges from a polarizing sheet is polarized parallel to the polarizing direction of the sheet.

If the original light is initially unpolarized, the transmitted intensity \( I \) is half the original intensity \( I_0 \):

\[
I = \frac{1}{2} I_0.
\]

(33-36)

If the original light is initially polarized, the transmitted intensity depends on the angle \( \theta \) between the polarization direction of the original light (the axis along which the fields oscillate) and the polarizing direction of the sheet:

\[
I = I_0 \cos^2 \theta.
\]

(33-38)

Geometrical Optics  Geometrical optics is an approximate treatment of light in which light waves are represented as straight-line rays.

Reflection and Refraction  When a light ray encounters a boundary between two transparent media, a reflected ray and a refracted ray generally appear. Both rays remain in the plane of incidence. The angle of reflection is equal to the angle of incidence, and the angle of refraction is related to the angle of incidence by Snell’s law,

\[
n_2 \sin \theta_2 = n_1 \sin \theta_1 \quad \text{(refraction)},
\]

(33-40)

where \( n_1 \) and \( n_2 \) are the indexes of refraction of the media in which the incident and refracted rays travel.

Total Internal Reflection  A wave encountering a boundary across which the index of refraction decreases will experience total internal reflection if the angle of incidence exceeds a critical angle \( \theta_c \), where

\[
\theta_c = \sin^{-1} \frac{n_2}{n_1} \quad \text{(critical angle)}.
\]

(33-45)

Polarization by Reflection  A reflected wave will be fully polarized, with its \( \vec{E} \) vectors perpendicular to the plane of incidence. If the incident, unpolarized wave strikes a boundary at the Brewster angle \( \theta_B \), where

\[
\theta_B = \tan^{-1} \frac{n_2}{n_1} \quad \text{(Brewster angle)}.
\]

(33-49)
Questions

1. If the magnetic field of a light wave oscillates parallel to a y axis and is given by \( B_y = B_0 \sin(kz - \omega t) \), (a) in what direction does the wave travel and (b) parallel to which axis does the associated electric field oscillate?

2. Suppose we rotate the second sheet in Fig. 33-15a, starting with the polarization direction aligned with the y axis \((\theta = 0)\) and ending with it aligned with the x axis \((\theta = 90^\circ)\). Which of the four curves in Fig. 33-26 best shows the intensity of the light through the three-sheet system during this 90° rotation?

3. (a) Figure 33-27 shows light reaching a polarizing sheet whose polarization direction is parallel to a y axis. We shall rotate the sheet 40° clockwise about the light’s indicated line of travel. During this rotation, does the fraction of the initial light intensity passed by the sheet increase, decrease, or remain the same if the light is (a) initially unpolarized, (b) initially polarized parallel to the x axis, and (c) initially polarized parallel to the y axis?

4. Figure 33-28 shows the electric and magnetic fields of an electromagnetic wave at a certain instant. Is the wave traveling into the page or out of the page?

5. In the arrangement of Fig. 33-15a, start with light that is initially polarized parallel to the x axis, and write the ratio of its final intensity \( I_f \) to its initial intensity \( I_i \) as \( I_i/I_f = A \cos^2 \theta \). What are \( A, n, \) and \( \theta \) if we rotate the polarization direction of the first sheet (a) 60° counterclockwise and (b) 90° clockwise from what is shown?

6. In Fig. 33-29, unpolarized light is sent into a system of five polarizing sheets. Their polarizing directions, measured counterclockwise from the positive direction of the y axis, are the following: sheet 1, 35°; sheet 2, 0°; sheet 3, 0°; sheet 4, 110°; sheet 5, 45°. Sheet 3 is then rotated 180° counterclockwise about the light ray. During that rotation, at what angles (measured counterclockwise from the y axis) is the transmission of light through the system eliminated?

7. Figure 33-30 shows rays of monochromatic light propagating through three materials \( a, b, \) and \( c \). Rank the materials according to the index of refraction, greatest first.

8. Figure 33-31 shows the multiple reflections of a light ray along a glass corridor where the walls are either parallel or perpendicular to one another. If the angle of incidence at point \( a \) is 30°, what are the angles of reflection of the light ray at points \( b, c, d, e, \) and \( f \)?

9. Figure 33-32 shows four long horizontal layers \( A-D \) of different materials, with air above and below them. The index of refraction of each material is given. Rays of light are sent into the left end of each layer as shown. In which layer is there the possibility of totally trapping the light in that layer so that, after many reflections, all the light reaches the right end of the layer?

10. The leftmost block in Fig. 33-33 depicts total internal reflection for light inside a material with an index of refraction \( n_i \) when air is outside the material. A light ray reaching point \( A \) from anywhere within the shaded region at the left (such as the ray shown) fully reflects at that point and ends up in the shaded region at the right. The other blocks show similar situations for two other materials. Rank the indexes of refraction of the three materials, greatest first.

11. Each part of Fig. 33-34 shows light that refracts through an interface between two materials. The incident ray (shown gray in the figure) consists of red and blue light. The approximate index of refraction for visible light is indicated for each material. Which of the three parts show physically possible refraction? (Hint: First consider the refraction in general, regardless of the color, and then consider how red and blue light refract differently.)

12. In Fig. 33-35, light travels from material \( a \), through three layers of other materials with surfaces parallel to one another, and then back into another layer of material \( a \). The refractions (but not the associated reflections) at the surfaces are shown. Rank the materials according to index of refraction, greatest first. (Hint: The parallel arrangement of the surfaces allows comparison.)
Module 33-1 Electromagnetic Waves

1. A certain helium–neon laser emits red light in a narrow band of wavelengths centered at 632.8 nm and with a “wavelength width” (such as on the scale of Fig. 33-1) of 0.0100 nm. What is the corresponding “frequency width” for the emission?

2. Project Seafarer was an ambitious program to construct an enormous antenna, buried underground on a site about 10 000 km² in area. Its purpose was to transmit signals to submarines while they were deeply submerged. If the effective wavelength were 1.0 × 10⁴ Earth radii, what would be the (a) frequency and (b) period of the radiations emitted? Ordinarily, electromagnetic radiations do not penetrate very far into conductors such as seawater, and so normal signals cannot reach the submarines.

3. From Fig. 33-2, approximate the (a) smaller and (b) larger wavelength at which the eye of a standard observer has half the eye’s maximum sensitivity. What are the (c) wavelength, (d) frequency, and (e) period of the light at which the eye is most sensitive?

4. About how far apart must you hold your hands for them to be separated by 1.0 nano-light-second (the distance light travels in 1.0 ns)?

5. SSM What inductance must be connected to a 17 pF capacitor in an oscillator capable of generating 550 nm (i.e., visible) electromagnetic waves? Comment on your answer.

6. What is the wavelength of the electromagnetic wave emitted by the oscillator–antenna system of Fig. 33-3 if \( L = 0.253 \, \mu \text{H} \) and \( C = 25.0 \, \text{pF} \)?

Module 33-2 Energy Transport and the Poynting Vector

7. What is the intensity of a traveling plane electromagnetic wave if \( B_m \) is 1.0 \times 10^{-4} \, \text{T}? Assume (unrealistically) that a TV station acts as a point source broadcasting isotropically at 1.0 MW. What is the intensity of the transmitted signal reaching Proxima Centauri, the star nearest our solar system, 4.3 ly away? (An alien civilization at that distance might be able to watch X-Files.) A light-year (ly) is the distance light travels in one year.

8. ILW Some neodymium–glass lasers can provide 100 TW of power in 1.0 ns pulses at a wavelength of 0.26 \, \mu\text{m}. How much energy is contained in a single pulse?

9. ILW A plane electromagnetic wave has a maximum electric field magnitude of 3.20 \times 10^{-4} \, \text{V/m}. Find the magnetic field amplitude.

10. ILW A plane electromagnetic wave traveling in the positive direction of an x axis in vacuum has components \( E_x = E_y = 0 \) and \( E_z = (2.0 \, \text{V/m}) \cos[(\pi \times 10^{15} \, \text{s}^{-1})(t - x/c)]. \) (a) What is the amplitude of the magnetic field component? (b) Parallel to which axis does the magnetic field oscillate? (c) When the electric field component is in the positive direction of the z axis at a certain point \( P \), what is the direction of the magnetic field component there?

11. ILW In a plane radio wave the maximum value of the electric field component is 5.00 \, \text{V/m}. Calculate (a) the maximum value of the magnetic field component and (b) the wave intensity.

12. Sunlight just outside Earth’s atmosphere has an intensity of 1.40 kW/m². Calculate (a) \( E_m \) and (b) \( B_m \) for sunlight there, assuming it to be a plane wave.

13. An isotropic point source emits light at wavelength 500 nm, at the rate of 200 W. A light detector is positioned 400 m from the source. What is the maximum rate \( dB/dt \) at which the magnetic component of the light changes with time at the detector’s location?

14. An airplane flying at a distance of 10 km from a radio transmitter receives a signal of intensity 10 \, \mu\text{W/m}². What is the amplitude of the (a) electric and (b) magnetic component of the signal at the airplane? (c) If the transmitter radiates uniformly over a hemisphere, what is the transmission power?

15. Frank D. Drake, an investigator in the SETI (Search for Extra-Terrestrial Intelligence) program, once said that the large radio telescope in Arecibo, Puerto Rico (Fig. 33-36), “can detect a signal which lays down on the entire surface of the earth a power of only one picowatt.” (a) What is the power that would be received by the Arecibo antenna for such a signal? The antenna diameter is 300 m. (b) What would be the power of an isotropic source at the center of our galaxy that could provide such a signal? The galactic center is \( 2.2 \times 10^{4} \) ly away. A light-year is the distance light travels in one year.

16. Extra-Terrestrial Intelligence) program, once said that the large radio telescope in Arecibo, Puerto Rico (Fig. 33-36), “can detect a signal which lays down on the entire surface of the earth a power of only one picowatt.” (a) What is the power that would be received by the Arecibo antenna for such a signal? The antenna diameter is 300 m. (b) What would be the power of an isotropic source at the center of our galaxy that could provide such a signal? The galactic center is \( 2.2 \times 10^{4} \) ly away. A light-year is the distance light travels in one year.
intensity $I$ versus the inverse square $r^{-2}$ of that distance. The vertical axis scale is set by $I_r = 200$ W/m², and the horizontal axis scale is set by $r^{-2} = 8.0$ m⁻². What is the power of the source?

**Module 33-3 Radiation Pressure**

19 SSM High-power lasers are used to compress a plasma (a gas of charged particles) by radiation pressure. A laser generating radiation pulses with peak power $1.5 \times 10^{10}$ MW is focused onto 1.0 mm² of high-electron-density plasma. Find the pressure exerted on the plasma if the plasma reflects all the light beams directly back along their paths.

20 Radiation from the Sun reaching Earth (just outside the atmosphere) has an intensity of $1.4\, \text{kW/m}^2$. (a) Assuming that Earth (and its atmosphere) behaves like a flat disk perpendicular to the Sun’s rays and that all the incident energy is absorbed, calculate the force on Earth due to radiation pressure. (b) For comparison, calculate the force due to the Sun’s gravitational attraction.

21 ILW What is the radiation pressure 1.5 m away from a 500 W lightbulb? Assume that the surface on which the pressure is exerted faces the bulb and is perfectly absorbing and that the bulb radiates uniformly in all directions.

22 A black, totally absorbing piece of cardboard of area $A = 2.0$ cm² intercepts light with an intensity of 10 W/m² from a camera strobe light. What radiation pressure is produced on the cardboard by the light?

23 Someone plans to float a small, totally absorbing sphere 0.500 m above an isotropic point source of light, so that the upward radiation force from the light matches the downward gravitational force on the sphere. The sphere’s density is $19.0 \, \text{g/cm}^3$, and its radius is 2.00 mm. (a) What power would be required of the light source? (b) Even if such a source were made, why would the support of the sphere be unstable?

24 SSM It has been proposed that a spaceship might be propelled in the solar system by radiation pressure, using a large sail made of foil. How large must the surface area of the sail be if the radiation force is to be equal in magnitude to the Sun’s gravitational attraction? Assume that the mass of the ship + sail is 1500 kg, that the sail is perfectly reflecting, and that the sail is oriented perpendicular to the Sun’s rays. See Appendix C for needed data. (With a larger sail, the ship is continuously driven away from the Sun.)

25 SSM Prove, for a plane electromagnetic wave that is normally incident on a flat surface, that the radiation pressure on the surface is equal to the energy density in the incident beam. (This relation between pressure and energy density holds no matter what fraction of the incident energy is reflected.)

26 In Fig. 33-38, a laser beam of power 4.60 W and diameter $D = 2.60$ mm is directed upward at one circular face (of diameter $d < 2.60$ mm) of a perfectly reflecting cylinder. The cylinder is levitated because the upward radiation force matches the downward gravitational force. If the cylinder’s density is $1.20 \, \text{g/cm}^3$, what is its height $H$?

27 SSM WWW A plane electromagnetic wave, with wavelength 3.0 m, travels in vacuum in the positive direction of an $x$ axis. The electric field, of amplitude 300 V/m, oscillates parallel to the $y$ axis. What are the (a) frequency, (b) angular frequency, and (c) angular wave number of the wave? (d) What is the amplitude of the magnetic field component? (e) Parallel to which axis does the magnetic field oscillate? (f) What is the time-averaged rate of energy flow in watts per square meter associated with this wave? The wave uniformly illuminates a surface of area 2.0 m². If the surface totally absorbs the wave, what are (g) the rate at which momentum is transferred to the surface and (h) the radiation pressure on the surface?

28 The average intensity of the solar radiation that strikes normally on a surface just outside Earth’s atmosphere is 1.4 kW/m². (a) What radiation pressure $p_r$ is exerted on this surface, assuming complete absorption? (b) For comparison, find the ratio of $p_r$ to Earth’s sea-level atmospheric pressure, which is $1.0 \times 10^5$ Pa.

29 SSM A small spaceship with a mass of only $1.5 \times 10^3$ kg (including an astronaut) is drifting in outer space with negligible gravitational forces acting on it. If the astronaut turns on a 10 kW laser beam, what speed will the ship attain in 1.0 day because of the momentum carried away by the beam?

30 A small laser emits light at power $5.00\, \text{mW}$ and wavelength 633 nm. The laser beam is focused (narrowed) until its diameter matches the 1266 nm diameter of a sphere placed in its path. The sphere is perfectly absorbing and has density $5.00 \times 10^3 \, \text{kg/m}^3$. What are (a) the beam intensity at the sphere’s location, (b) the radiation pressure on the sphere, (c) the magnitude of the corresponding force, and (d) the magnitude of the acceleration that force alone would give the sphere?

31 As a comet swings around the Sun, ice on the comet’s surface vaporizes, releasing trapped dust particles and ions. The ions, because they are electrically charged, are forced by the electrically charged solar wind into a straight ion tail that points radially away from the Sun (Fig. 33-39). The electrically neutral dust particles are pushed radially outward from the Sun by the radiation force on them from sunlight. Assume that the dust particles are spherical, have density $3.5 \times 10^5 \, \text{kg/m}^3$, and are totally absorbing. (a) What radius must a particle have in order to follow a straight path, like path 2 in the figure? (b) If its radius is larger, does its path curve away from the Sun (like path 1) or toward the Sun (like path 3)?

**Module 33-4 Polarization**

32 In Fig. 33-40, initially unpolarized light is sent into a system of three polarizing sheets whose polarizing directions make angles
of \( \theta_1 = \theta_2 = \theta_3 = 50^\circ \) with the direction of the y axis. What percentage of the initial intensity is transmitted by the system? (Hint: Be careful with the angles.)

40 In Fig. 33-40, initially unpolarized light is sent into a system of three polarizing sheets whose polarizing directions make angles of \( \theta_1 = 40^\circ, \theta_2 = 20^\circ \), and \( \theta_3 = 40^\circ \) with the direction of the y axis. What percentage of the light's initial intensity is transmitted by the system? (Hint: Be careful with the angles.)

41 A beam of unpolarized light is sent into a system of two polarizing sheets with polarization parallel to a y axis, is sent into a system of two polarizing sheets with polarization directions at angles \( \theta_1 = 70^\circ \) and \( \theta_2 = 90^\circ \) to the y axis. What is the intensity of the light transmitted by the system?

42 In Fig. 33-41, a beam of unpolarized light, with intensity 43 W/m\(^2\), is sent into a system of two polarizing sheets with polarization directions at angles \( \theta_1 = 70^\circ \) and \( \theta_2 = 90^\circ \) to the y axis. What is the intensity of the light transmitted by the two-sheet system?

43 At a beach the light is generally partially polarized due to reflections off sand and water. At a particular beach on a particular day near sundown, the horizontal component of the electric field vector is 2.3 times the vertical component. A standing sunbather puts on polarizing sunglasses; the glasses eliminate the horizontal field component. (a) What fraction of the light intensity received before the glasses were put on now reaches the sunbather's eyes? (b) The sunbather, still wearing the glasses, lies on his side. What fraction of the light intensity received before the glasses were put on now reaches his eyes?

44 We want to rotate the direction of polarization of a beam of polarized light through 90° by sending the beam through one or more polarizing sheets. (a) What is the minimum number of sheets required? (b) What is the minimum number of sheets required if the transmitted intensity is to be more than 60% of the original intensity?

45 Unpolarized light of intensity 10 mW/m\(^2\) is sent into a polarizing sheet as in Fig. 33-11. What are (a) the amplitude of the electric field component of the transmitted light and (b) the radiation pressure on the sheet due to its absorbing some of the light?
Module 33-5 Reflection and Refraction

45 When the rectangular metal tank in Fig. 33-46 is filled to the top with an unknown liquid, observer O, with eyes level with the top of the tank, can just see corner E. A ray that refracts toward O at the top surface of the liquid is shown. If $D = 85.0 \text{ cm}$ and $L = 1.10 \text{ m}$, what is the index of refraction of the liquid?

46 In Fig. 33-47a, a light ray in an underlying material is incident at angle $\theta_1$ on a boundary with water, and some of the light refracts into the water. There are two choices of underlying material. For each, the angle of refraction $\theta_2$ versus the incident angle $\theta_1$ is given in Fig. 33-47b. The horizontal axis scale is set by $\theta_1 = 90^\circ$. Without calculation, determine whether the index of refraction of (a) material 1 and (b) material 2 is greater or less than the index of water ($n = 1.33$). What is the index of refraction of (c) material 1 and (d) material 2?

47 Light in vacuum is incident on the surface of a glass slab. In the vacuum the beam makes an angle of 32.0° with the normal to the surface, while in the glass it makes an angle of 21.0° with the normal. What is the index of refraction of the glass?

48 In Fig. 33-48a, a light ray in water is incident at angle $\theta_1$ on a boundary with an underlying material, into which some of the light refracts. There are two choices of underlying material. For each, the angle of refraction $\theta_2$ versus the incident angle $\theta_1$ is given in Fig. 33-48b. The vertical axis scale is set by $\theta_2 = 90^\circ$. Without calculation, determine whether the index of refraction of (a) material 1 and (b) material 2 is greater or less than the index of water ($n = 1.33$). What is the index of refraction of (c) material 1 and (d) material 2?

49 Figure 33-49 shows light reflecting from two perpendicular reflecting surfaces A and B. Find the angle between the incoming ray $i$ and the outgoing ray $r$.

50 In Fig. 33-50a, a beam of light in material 1 is incident on a boundary at an angle $\theta_1 = 40^\circ$. Some of the light travels through material 2, and then some of it emerges into material 3. The two boundaries between the three materials are parallel. The final direction of the beam depends, in part, on the index of refraction $n_3$ of the third material. Figure 33-50b gives the angle of refraction $\theta_3$ in that material versus $n_3$ for a range of possible $n_3$ values. The vertical axis scale is set by $\theta_3 = 30.0^\circ$ and $\theta_3 = 50.0^\circ$. (a) What is the index of refraction of material 1, or is the index impossible to calculate without more information? (b) What is the index of refraction of material 2, or is the index impossible to calculate without more information? (c) If $\theta_1$ is changed to 70° and the index of refraction of material 3 is 2.4, what is $\theta_3$?

51 In Fig. 33-51, light is incident at angle $\theta_1 = 40.1^\circ$ on a boundary between two transparent materials. Some of the light travels down through the next three layers of transparent materials, while some of it reflects upward and then escapes into the air. If $n_1 = 1.30$, $n_2 = 1.40$, $n_3 = 1.32$, and $n_4 = 1.45$, what is the value of (a) $\theta_2$ in the air and (b) $\theta_4$ in the bottom material?

52 In Fig. 33-52a, a beam of light in material 1 is incident on a boundary at an angle of $\theta_1 = 30^\circ$. The extent of refraction of the light into material 2 depends, in part, on the index of refraction $n_2$ of material 2. Figure 33-52b gives the angle of refraction $\theta_2$ versus $n_2$ for a range of possible $n_2$ values. The vertical axis scale is set by $\theta_2 = 20.0^\circ$ and $\theta_2 = 40.0^\circ$. (a) What is the index of refraction of...
material 1? (b) If the incident angle is changed to 60° and material 2 has \( n_2 = 2.4 \), then what is angle \( \theta_b \)?

**53** SSM WWW ILW

In Fig. 33-53, a ray is incident on one face of a triangular glass prism in air. The angle of incidence \( \theta \) is chosen so that the emerging ray also makes the same angle \( \theta \) with the normal to the other face. Show that the index of refraction \( n \) of the glass prism is given by

\[
n = \frac{\sin \frac{\phi}{2}}{\sin \frac{\theta}{2}} \sin \phi,
\]

where \( \phi \) is the vertex angle of the prism and \( \phi \) is the deviation angle, the total angle through which the beam is turned in passing through the prism. (Under these conditions the deviation angle \( \phi \) has the smallest possible value, which is called the angle of minimum deviation.)

**54** Dispersion in a window pane. In Fig. 33-54, a beam of white light is incident at angle \( \theta = 50° \) on a common window pane (shown in cross section). For the pane’s type of glass, the index of refraction for visible light ranges from 1.524 at the blue end of the spectrum to 1.509 at the red end. The two sides of the pane are parallel. What is the angular spread of the colors in the beam (a) when the light enters the pane and (b) when it emerges from the opposite side? (Hint: When you look at an object through a window pane, are the colors in the light from the object dispersed as shown in, say, Fig. 33-20?)

**55** SSM

In Fig. 33-55, a 2.00-m-long vertical pole extends from the bottom of a swimming pool to a point 50.0 cm above the water. Sunlight is incident at angle \( \theta = 55.0° \). What is the length of the shadow of the pole on the level bottom of the pool?

**56** Rainbows from square drops. Suppose that, on some surreal world, raindrops had a square cross section and always fell with one face horizontal. Figure 33-56 shows such a falling drop, with a white beam of sunlight incident at \( \theta = 70.0° \) at point \( P \). The part of the light that enters the drop then travels to point \( A \), where some of it refracts out into the air and the rest reflects. That reflected light then travels to point \( B \), where again some of the light refracts out into the air and the rest reflects. What is the difference in the angles of the red light (\( n = 1.331 \)) and the blue light (\( n = 1.343 \)) that emerge at (a) point \( A \) and (b) point \( B \)? (This angular difference in the light emerging at, say, point \( A \) would be the rainbow’s angular width.)

**Module 33-6 Total Internal Reflection**

**57** A point source of light is 80.0 cm below the surface of a body of water. Find the diameter of the circle at the surface through which light emerges from the water.

**58** The index of refraction of benzene is 1.8. What is the critical angle for a light ray traveling in benzene toward a flat layer of air above the benzene?

**59** SSM ILW

In Fig. 33-57, a ray of light is perpendicular to the face \( ab \) of a glass prism (\( n = 1.52 \)). Find the largest value for the angle \( \phi \) so that the ray is totally reflected at face \( ac \) if the prism is immersed (a) in air and (b) in water.

**60** In Fig. 33-58, light from ray \( A \) refracts from material 1 (\( n_1 = 1.60 \)) into a thin layer of material 2 (\( n_2 = 1.80 \)), crosses that layer, and is then incident at the critical angle on the interface between materials 2 and 3 (\( n_3 = 1.30 \)). (a) What is the value of incident angle \( \theta_u \)? (b) If \( \theta_u \) is decreased, does part of the light refract into material 3?

Light from ray \( B \) refracts from material 1 into the thin layer, crosses that layer, and is then incident at the critical angle on the interface between materials 2 and 3. (c) What is the value of incident angle \( \theta_b \)? (d) If \( \theta_b \) is decreased, does part of the light refract into material 3?

**61** In Fig. 33-59, light initially in material 1 refracts into material 2, crosses that material, and is then incident at the critical angle on the interface between materials 2 and 3. The indexes of refraction are \( n_1 = 1.60 \), \( n_2 = 1.40 \), and \( n_3 = 1.20 \). (a) What is angle \( \theta_f \)? (b) If \( \theta_f \) is increased, is there refraction of light into material 3?

**62** A catfish is 2.00 m below the surface of a smooth lake. (a) What is the diameter of the circle on the surface through which the fish can see the world outside the water? (b) If the fish descends, does the diameter of the circle increase, decrease, or remain the same?

**63** In Fig. 33-60, light enters a 90° triangular prism at point \( P \) with incident angle \( \theta \), and then some of it refracts at point \( Q \) with an angle of refraction of 90°. (a) What is the index of refraction of the prism in terms of \( \theta_f \)? (b) What, numerically, is the maximum value that the index of refraction can have? Does light emerge at \( Q \) if the incident angle at \( P \) is (c) increased slightly and (d) decreased slightly?
64 Suppose the prism of Fig. 33-53 has apex angle $\phi = 60.0^\circ$ and index of refraction $n = 1.60.$ (a) What is the smallest angle of incidence $\theta$ for which a ray can enter the left face of the prism and exit the right face? (b) What angle of incidence $\theta$ is required for the ray to exit the prism with an identical angle $\phi$ for its refraction, as it does in Fig. 33-53?

65 Figure 33-61 depicts a simple optical fiber: a plastic core ($n_1 = 1.58$) is surrounded by a plastic sheath ($n_2 = 1.53$). A light ray is incident on one end of the fiber at angle $\theta$. The ray is to undergo total internal reflection at point $A$, where it encounters the core–sheath boundary. (Thus there is no loss of light through that boundary.) What is the maximum value of $\theta$ that allows total internal reflection at $A$?

66 In Fig. 33-62, a light ray in air is incident at angle $\theta_1$ on a block of transparent plastic with an index of refraction of $1.56$. The dimensions indicated are $H = 2.00$ cm and $W = 3.00$ cm. The light passes through the block to one of its sides and there undergoes reflection (inside the block) and possibly refraction (out into the air). This is the point of first reflection. The reflected light then passes through the block to another of its sides—a point of second reflection. If $\theta_1 = 40^\circ$, on which side is the point of (a) first reflection and (b) second reflection? If there is refraction at the point of (c) first reflection and (d) second reflection, give the angle of refraction; if not, answer “none.” If $\theta_1 = 70^\circ$, on which side is the point of (e) first reflection and (f) second reflection? If there is refraction at the point of (g) first reflection and (h) second reflection, give the angle of refraction; if not, answer “none.”

67 In the ray diagram of Fig. 33-63, where the angles are not drawn to scale, the ray is incident at the critical angle on the interface between materials 2 and 3. Angle $\phi = 60.0^\circ$, and two of the indexes of refraction are $n_1 = 1.70$ and $n_2 = 1.60$. Find (a) index of refraction $n_3$ and (b) angle $\theta$. (c) If $\theta$ is decreased, does light refract into material 3?

68 (a) At what angle of incidence will the light reflected from water be completely polarized? (b) Does this angle depend on the wavelength of the light?

69 SSM Light that is traveling in water (with an index of refraction 1.33) is incident on a plate of glass (with index of refraction 1.53). At what angle of incidence does the reflected light end up fully polarized?

70 In Fig. 33-64, a light ray in air is incident on a flat layer of material 2 that has an index of refraction $n_2 = 1.5$. Beneath material 2 is material 3 with an index of refraction $n_3$. The ray is incident on the air–material 2 interface at the Brewster angle for that interface. The ray of light refracted into material 3 happens to be incident on the material 2–material 3 interface at the Brewster angle for that interface. What is the value of $n_3$?

Additional Problems

71 SSM (a) How long does it take a radio signal to travel 150 km from a transmitter to a receiving antenna? (b) We see a full Moon by reflected sunlight. How much earlier did the light that enters our eye leave the Sun? The Earth–Moon and Earth–Sun distances are $3.8 \times 10^8$ km and $1.5 \times 10^9$ km, respectively. (c) What is the round-trip travel time for light between Earth and a spaceship orbiting Saturn, 1.3 \times 10^9 km distant? (d) The Crab nebula, which is about 6500 light-years (ly) distant, is thought to be the result of a supernova explosion recorded by Chinese astronomers in A.D. 1054. In approximately what year did the explosion actually occur? (When we look into the night sky, we are effectively looking back in time.)

72 An electromagnetic wave with frequency $4.00 \times 10^{14}$ Hz travels through vacuum in the positive direction of an $x$ axis. The wave has its electric field oscillating parallel to the $y$ axis, with an amplitude $E_m$. At time $t = 0$, the electric field at point $P$ on the $x$ axis has a value of $+E_m/4$ and is decreasing with time. What is the distance along the $x$ axis from point $P$ to the first point with $E = 0$ if we search in (a) the negative direction and (b) the positive direction of the $x$ axis?

73 SSM The electric component of a beam of polarized light is $E_y = (5.00 \text{ V/m}) \sin[(1.00 \times 10^6 \text{ m}^{-1})z + \omega t]$. (a) Write an expression for the magnetic field component of the wave, including a value for $\omega$. What are the (b) wavelength, (c) period, and (d) intensity of this light? (e) Parallel to which axis does the magnetic field oscillate? (f) In which region of the electromagnetic spectrum is this wave?

74 A particle in the solar system is under the combined influence of the Sun’s gravitational attraction and the radiation force due to the Sun’s rays. Assume that the particle is a sphere of density $1.0 \times 10^3$ kg/m$^3$ and that all the incident light is absorbed. (a) Show that, if its radius is less than some critical radius $R$, the particle will be blown out of the solar system. (b) Calculate the critical radius.
75 SSM  In Fig. 33-65, a light ray enters a glass slab at point \( A \) at incident angle \( \theta_i = 45.0^\circ \) and then undergoes total internal reflection at point \( B \). (The reflection at \( A \) is not shown.) What minimum value for the index of refraction of the glass can be inferred from this information?

76 In Fig. 33-66, unpolarized light with an intensity of 25 W/m\(^2\) is sent into a system of four polarizing sheets with polarizing directions at angles \( \theta_1 = 40^\circ \), \( \theta_2 = 20^\circ \), \( \theta_3 = 20^\circ \), and \( \theta_4 = 30^\circ \). What is the intensity of the light that emerges from the system?

77 Rainbow. Figure 33-67 shows a light ray entering and then leaving a falling, spherical raindrop after one internal reflection (see Fig. 33-21a). The final direction of travel is deviated (turned) from the initial direction of travel by angular deviation \( \theta_{\text{dev}} \). (a) Show that \( \theta_{\text{dev}} \) is

\[
\theta_{\text{dev}} = 180^\circ + 2\theta_i - 4\theta_r,
\]

where \( \theta_i \) is the angle of incidence of the ray on the drop and \( \theta_r \) is the angle of refraction of the ray within the drop. (b) Using Snell's law, substitute for \( \theta_i \) in terms of \( \theta_r \) and the index of refraction \( n \) of the water. Then, on a graphing calculator or with a computer graphing package, graph \( \theta_{\text{dev}} \) versus \( \theta_r \) for the range of possible \( \theta_r \) values and for \( n = 1.331 \) for red light (at one end of the visible spectrum) and \( n = 1.333 \) for blue light (at the other end).

The red-light curve and the blue-light curve have different minima, which means that there is a different angle of minimum deviation for each color. The light of any given color that leaves the drop at that color’s angle of minimum deviation is especially bright because rays bunch up at that angle. Thus, the bright red light leaves the drop at one angle and the bright blue light leaves it at another angle.

Determine the angle of minimum deviation from the \( \theta_{\text{dev}} \) curve for (c) red light and (d) blue light. (e) If these colors form the inner and outer edges of a rainbow (Fig. 33-21a), what is the angular width of the rainbow?

78 The primary rainbow described in Problem 77 is the type commonly seen in regions where rainbows appear. It is produced by light reflecting once inside the drops. Rarer is the secondary rainbow described in Module 33-5, produced by light reflecting twice inside the drops (Fig. 33-68a). (a) Show that the angular deviation of light entering and then leaving a spherical water drop is

\[
\theta_{\text{dev}} = (180^\circ)k + 2\theta_i - 2(k + 1)\theta_r,
\]

where \( k \) is the number of internal reflections. Using the procedure of Problem 77, find the angle of minimum deviation for (b) red light and (c) blue light in a secondary rainbow. (d) What is the angular width of that rainbow (Fig. 33-21d)?

The tertiary rainbow depends on three internal reflections (Fig. 33-68b). It probably occurs but, as noted in Module 33-5, cannot be seen with the eye because it is very faint and lies in the bright sky surrounding the Sun. What is the angle of minimum deviation for (e) the red light and (f) the blue light in this rainbow? (g) What is the rainbow’s angular width?

79 SSM (a) Prove that a ray of light incident on the surface of a sheet of plate glass of thickness \( t \) emerges from the opposite face parallel to its initial direction but displaced sideways, as in Fig. 33-69. (b) Show that, for small angles of incidence \( \theta \), this displacement is given by

\[
x = t \theta \frac{n - 1}{n},
\]

where \( n \) is the index of refraction of the glass and \( \theta \) is measured in radians.

80 An electromagnetic wave is traveling in the negative direction of a \( y \) axis. At a particular position and time, the electric field is directed along the positive direction of the \( z \) axis and has a magnitude of 100 V/m. What are the (a) magnitude and (b) direction of the corresponding magnetic field?
81. The magnetic component of a polarized wave of light is
\[ B_y = (4.0 \times 10^{-6} \text{T}) \sin((1.57 \times 10^3 \text{ m}^{-1})y + \omega t). \]
(a) Parallel to which axis is the light polarized? What are the (b) frequency and (c) intensity of the light?

82. In Fig. 33-70, unpolarized light is sent into the system of three polarizing sheets, where the polarizing directions of the first and third sheets are at angles \( \theta_1 = 30^\circ \) (counterclockwise) and \( \theta_2 = 30^\circ \) (clockwise). What fraction of the initial light intensity emerges from the system?

83. A ray of white light traveling through fused quartz is incident at a quartz–air interface at angle \( \theta_i \). Assume that the index of refraction of quartz is \( n = 1.456 \) at the red end of the visible range and \( n = 1.470 \) at the blue end. If \( \theta_i \) is (a) 42.00°, (b) 43.10°, and (c) 44.00°, is the refracted light white, white dominated by the red end of the visible range, or white dominated by the blue end of the visible range, or is there no refracted light?

84. Three polarizing sheets are stacked. The first and third are crossed; the one between has its polarizing direction at 45.0° to the polarizing directions of the other two. What fraction of the intensity of an originally unpolarized beam is transmitted by the stack?

85. In a region of space where gravitational forces can be neglected, a sphere is accelerated by a uniform light beam of intensity 6.0 mW/m². The sphere is totally absorbing and has a radius of 2.0 \( \mu \text{m} \) and a uniform density of \( 5.0 \times 10^3 \text{ kg/m}^3 \). What is the magnitude of the sphere’s acceleration due to the light?

86. An unpolarized beam of light is sent into a stack of four polarizing sheets, oriented so that the angle between the polarizing directions of adjacent sheets is 30°. What fraction of the incident intensity is transmitted by the system?

87. During a test, a NATO surveillance radar system, operating at 12 GHz at 180 kW of power, attempts to detect an incoming stealth aircraft at 90 km. Assume that the radar beam is emitted uniformly over a hemisphere. (a) What is the intensity of the beam when the beam reaches the aircraft’s location? The aircraft reflects radar waves as though it has a cross-sectional area of only 0.22 m². (b) What is the power of the aircraft’s reflection? Assume that the beam is reflected uniformly over a hemisphere. Back at the radar site, what are (c) the intensity, (d) the maximum value of the electric field vector, and (e) the rms value of the magnetic field of the reflected radar beam?

88. The magnetic component of an electromagnetic wave in vacuum has an amplitude of 85.8 nT and an angular wave number of 4.00 m⁻¹. What are (a) the frequency of the wave, (b) the rms value of the electric component, and (c) the intensity of the light?

89. Calculate the (a) upper and (b) lower limit of the Brewster angle for white light incident on fused quartz. Assume that the wavelength limits of the light are 400 and 700 nm.

90. In Fig. 33-71, two light rays pass from air through five layers of transparent plastic and then back into air. The layers have parallel interfaces and unknown thicknesses; their indexes of refraction are \( n_1 = 1.7, n_2 = 1.6, n_3 = 1.5, n_4 = 1.4, \) and \( n_5 = 1.6 \). Ray \( b \) is incident at angle \( \theta_b = 20^\circ \). Relative to a normal at the last interface, at what angle do (a) ray \( a \) and (b) ray \( b \) emerge? (Hint: Solving the problem algebraically can save time.) If the air at the left and right sides in the figure were, instead, glass with index of refraction 1.5, at what angle would (c) ray \( a \) and (d) ray \( b \) emerge?

91. A helium–neon laser, radiating at 632.8 nm, has a power output of 3.0 mW. The beam diverges (spreads) at angle \( 3.0 \text{ mrad} \). What is the power of the point source providing that intensity at that distance?

92. In about A.D. 150, Claudius Ptolemy gave the following measured values for the angle of incidence \( \theta_i \) and the angle of refraction \( \theta_r \) for a light beam passing from air to water:

<table>
<thead>
<tr>
<th>( \theta_i )</th>
<th>( \theta_r )</th>
</tr>
</thead>
<tbody>
<tr>
<td>10°</td>
<td>8°</td>
</tr>
<tr>
<td>20°</td>
<td>15°30'</td>
</tr>
<tr>
<td>30°</td>
<td>22°30'</td>
</tr>
<tr>
<td>40°</td>
<td>29°</td>
</tr>
</tbody>
</table>

Assuming these data are consistent with the law of refraction, use them to find the index of refraction of water. These data are interesting as perhaps the oldest recorded physical measurements.

93. A beam of initially unpolarized light is sent through two polarizing sheets placed one on top of the other. What must be the angle between the polarizing directions of the sheets if the intensity of the transmitted light is to be one-third the incident intensity?

94. In Fig. 33-73, a long, straight copper wire (diameter 2.50 mm and resistance 1.00 \( \Omega \) per 300 m) carries a uniform current of 25.0 A in the positive \( x \) direction. For point \( P \) on the wire’s surface, calculate the magnitudes of (a) the electric field \( \vec{E} \), (b) the magnetic field \( \vec{B} \), and (c) the Poynting vector \( \vec{S} \), and (d) determine the direction of \( \vec{S} \).

95. In about 300 B.C. the ancient Greeks used a right-angled triangle to measure the distance to the sun. They placed the triangle on the ground with one leg parallel to the plane of the earth and the other leg along a line from the point on the earth to the sun. If the angle \( \theta_1 \) of the triangle is 46°, the length of the leg along the line from the point on the earth to the sun is 1.00×10⁸ m, and the length of the leg parallel to the plane of the earth is 0.54×10⁶ m, what is the radius of the sun?
Figure 33-74 shows a cylindrical resistor of length $l$, radius $a$, and resistivity $\rho$, carrying current $i$. (a) Show that the Poynting vector $\vec{S}$ at the surface of the resistor is everywhere directed normal to the surface, as shown. (b) Show that the rate $P$ at which energy flows into the resistor through its cylindrical surface, calculated by integrating the Poynting vector over this surface, is equal to the rate at which thermal energy is produced:

$$\int \vec{S} \cdot d\vec{A} = \dot{\varepsilon} R,$$

where $d\vec{A}$ is an element of area on the cylindrical surface and $R$ is the resistance.

A thin, totally absorbing sheet of mass $m$, face area $A$, and specific heat $c$, is fully illuminated by a perpendicular beam of a plane electromagnetic wave. The magnitude of the maximum electric field of the wave is $E_0$. What is the rate $dT/dt$ at which the sheet’s temperature increases due to the absorption of the wave?

Two polarizing sheets, one directly above the other, transmit $\rho\%$ of the initially unpolarized light that is perpendicularly incident on the top sheet. What is the angle between the polarizing directions of the two sheets?

A laser beam of intensity $I$ reflects from a flat, totally reflecting surface of area $A$, with a normal at angle $\theta$ with the beam. Write an expression for the beam’s radiation pressure $p_r(\theta)$ on the surface in terms of the beam’s pressure $p_r$ when $\theta = 0^\circ$.

A beam of intensity $I$ reflects from a long, totally reflecting cylinder of radius $R$; the beam is perpendicular to the central axis of the cylinder and has a diameter larger than $2R$. What is the beam’s force per unit length on the cylinder?

In Fig. 33-75, unpolarized light is sent into a system of three polarizing sheets, where the polarizing directions of the first and second sheets are at angles $\theta_1 = 20^\circ$ and $\theta_2 = 40^\circ$. What fraction of the initial light intensity emerges from the system?

In Fig. 33-76, unpolarized light is sent into a system of three polarizing sheets with polarizing directions at angles $\theta_1 = 20^\circ$, $\theta_2 = 60^\circ$, and $\theta_3 = 40^\circ$. What fraction of the initial light intensity emerges from the system?

A square, perfectly reflecting surface is oriented in space to be perpendicular to the light rays from the Sun. The surface has an edge length of 2.0 m and is located $3.0 \times 10^{11}$ m from the Sun’s center. What is the radiation force on the surface from the light rays?

The rms value of the electric field in a certain light wave is 0.200 V/m. What is the amplitude of the associated magnetic field?

In Fig. 33-77, an albatross glides at a constant 15 m/s horizontally above level ground, moving in a vertical plane that contains the Sun. It glides toward a wall of height $h = 2.0$ m, which it will just barely clear. At that time of day, the angle of the Sun relative to the ground is $\theta = 30^\circ$. At what speed does the shadow of the albatross move (a) across the level ground and then (b) up the wall? Suppose that later a hawk happens to glide along the same path, also at 15 m/s. You see that when its shadow reaches the wall, the speed of the shadow noticeably increases. (c) Is the Sun now higher or lower in the sky than when the albatross flew by earlier? (d) If the speed of the hawk’s shadow on the wall is 45 m/s, what is the angle $\theta$ of the Sun just then?

The magnetic component of a polarized wave of light is given by $B_x = (4.00 \mu T) \sin[k_y(x + (2.00 \times 10^3 s^{-1})t)]$. (a) In which direction does the wave travel, (b) parallel to which axis is it polarized, and (c) what is its intensity? (d) Write an expression for the electric field of the wave, including a value for the angular wave number. (e) What is the wavelength? (f) In which region of the electromagnetic spectrum is this electromagnetic wave?

In Fig. 33-78, where $n_1 = 1.70$, $n_2 = 1.50$, and $n_3 = 1.30$, light refracts from material 1 into material 2. If it is incident at point A at the critical angle for the interface between materials 2 and 3, what are (a) the angle of refraction at point B and (b) the initial angle $\theta^i$? If, instead, light is incident at B at the critical angle for the interface between materials 2 and 3, what are (c) the angle of refraction at point A and (d) the initial angle $\theta^i$? If, instead of all that, light is incident at point A at Brewster’s angle for the interface between materials 2 and 3, what are (e) the angle of refraction at point B and (f) the initial angle $\theta^i$?

When red light in vacuum is incident at the Brewster angle on a certain glass slab, the angle of refraction is $32.0^\circ$. What are (a) the index of refraction of the glass and (b) the Brewster angle?

Start from Eqs. 33-11 and 33-17 and show that $E(x, t)$ and $B(x, t)$, the electric and magnetic field components of a plane traveling electromagnetic wave, must satisfy the “wave equations”

$$\frac{\partial^2 E}{\partial t^2} = c^2 \frac{\partial^2 E}{\partial x^2}$$

and

$$\frac{\partial^2 B}{\partial t^2} = c^2 \frac{\partial^2 B}{\partial x^2}.$$

(a) Show that Eqs. 33-1 and 33-2 satisfy the wave equations displayed in Problem 108. (b) Show that any expressions of the form $E = E_m f(kx \pm \omega t)$ and $B = B_m f(kx \pm \omega t)$, where $f(kx \pm \omega t)$ denotes an arbitrary function, also satisfy these wave equations.

A point source of light emits isotropically with a power of 200 W. What is the force due to the light on a totally absorbing sphere of radius 2.0 cm at a distance of 20 m from the source?
What Is Physics?

One goal of physics is to discover the basic laws governing light, such as the law of refraction. A broader goal is to put those laws to use, and perhaps the most important use is the production of images. The first photographic images, made in 1824, were only novelties, but our world now thrives on images. Huge industries are based on the production of images on television, computer, and theater screens. Images from satellites guide military strategists during times of conflict and environmental strategists during times of blight. Camera surveillance can make a subway system more secure, but it can also invade the privacy of unsuspecting citizens. Physiologists and medical engineers are still puzzled by how images are produced by the human eye and the visual cortex of the brain, but they have managed to create mental images in some sightless people by electrical stimulation of the brain’s visual cortex.

Our first step in this chapter is to define and classify images. Then we examine several basic ways in which they can be produced.

Two Types of Image

For you to see, say, a penguin, your eye must intercept some of the light rays spreading from the penguin and then redirect them onto the retina at the rear of the eye. Your visual system, starting with the retina and ending with the visual cortex at the rear of your brain, automatically and subconsciously processes the information provided by the light. That system identifies edges, orientations,
textures, shapes, and colors and then rapidly brings to your consciousness an image (a reproduction derived from light) of the penguin; you perceive and recognize the penguin as being in the direction from which the light rays came and at the proper distance.

Your visual system goes through this processing and recognition even if the light rays do not come directly from the penguin, but instead reflect toward you from a mirror or refract through the lenses in a pair of binoculars. However, you now see the penguin in the direction from which the light rays came after they reflected or refracted, and the distance you perceive may be quite different from the penguin’s true distance.

For example, if the light rays have been reflected toward you from a standard flat mirror, the penguin appears to be behind the mirror because the rays you intercept come from that direction. Of course, the penguin is not back there. This type of image, which is called a virtual image, truly exists only within the brain but nevertheless is said to exist at the perceived location.

A real image differs in that it can be formed on a surface, such as a card or a movie screen. You can see a real image (otherwise movie theaters would be empty), but the existence of the image does not depend on your seeing it and it is present even if you are not. Before we discuss real and virtual images in detail, let’s examine a natural virtual image.

A Common Mirage

A common example of a virtual image is a pool of water that appears to lie on the road some distance ahead of you on a sunny day, but that you can never reach. The pool is a mirage (a type of illusion), formed by light rays coming from the low section of the sky in front of you (Fig. 34-1a). As the rays approach the road, they travel through progressively warmer air that has been heated by the road, which is usually relatively warm. With an increase in air temperature, the density of the air — and hence the index of refraction of the air — decreases slightly. Thus, as the rays descend, encountering progressively smaller indexes of refraction, they continuously bend toward the horizontal (Fig. 34-1b).

Once a ray is horizontal, somewhat above the road’s surface, it still bends because the lower portion of each associated wavefront is in slightly warmer air and is moving slightly faster than the upper portion of the wavefront (Fig. 34-1c). This nonuniform motion of the wavefronts bends the ray upward. As the ray then ascends, it continues to bend upward through progressively greater indexes of refraction (Fig. 34-1d).

If you intercept some of this light, your visual system automatically infers that it originated along a backward extension of the rays you have intercepted and, to make sense of the light, assumes that it came from the road surface. If the light happens to be bluish from blue sky, the mirage appears bluish, like water. Because the air is probably turbulent due to the heating, the mirage shimmies, as if water waves were present. The bluish coloring and the shimmy enhance the illusion of a pool of water, but you are actually seeing a virtual image of a low section of the sky. As you travel toward the illusionary pool, you no longer intercept the shallow refracted rays and the illusion disappears.

![Figure 34-1](image-url) (a) A ray from a low section of the sky refracts through air that is heated by a road (without reaching the road). An observer who intercepts the light perceives it to be from a pool of water on the road. (b) Bending (exaggerated) of a light ray descending across an imaginary boundary from warm air to warmer air. (c) Shifting of wavefronts and associated bending of a ray, which occur because the lower ends of wavefronts move faster in warmer air. (d) Bending of a ray ascending across an imaginary boundary to warm air from warmer air.
**Plane Mirrors**

A mirror is a surface that can reflect a beam of light in one direction instead of either scattering it widely in many directions or absorbing it. A shiny metal surface acts as a mirror; a concrete wall does not. In this module we examine the images that a plane mirror (a flat reflecting surface) can produce.

Figure 34-2 shows a point source of light \( O \), which we shall call the object, at a perpendicular distance \( p \) in front of a plane mirror. The light that is incident on the mirror is represented with rays spreading from \( O \). The reflection of that light is represented with reflected rays spreading from the mirror. If we extend the reflected rays backward (behind the mirror), we find that the extensions intersect at a point that is a perpendicular distance \( i \) behind the mirror.

If you look into the mirror of Fig. 34-2, your eyes intercept some of the reflected light. To make sense of what you see, you perceive a point source of light located at the point of intersection of the extensions. This point source is the image \( I \) of object \( O \). It is called a point image because it is a point, and it is a virtual image because the rays do not actually pass through it. (As you will see, rays do pass through a point of intersection for a real image.)

**Ray Tracing.** Figure 34-3 shows two rays selected from the many rays in Fig. 34-2. One reaches the mirror at point \( b \), perpendicularly. The other reaches it at an arbitrary point \( a \), with an angle of incidence \( \theta \). The extensions of the two reflected rays are also shown. The right triangles \( aOb \) and \( aIb \) have a common side and three equal angles and are thus congruent (equal in size); so their horizontal sides have the same length. That is,

\[
Ib = Ob, \quad (34-1)
\]

where \( Ib \) and \( Ob \) are the distances from the mirror to the image and the object, respectively. Equation 34-1 tells us that the image is as far behind the mirror as the object is in front of it. By convention (that is, to get our equations to work out), object distances \( p \) are taken to be positive quantities and image distances \( i \) for virtual images (as here) are taken to be negative quantities. Thus, Eq. 34-1 can be written as \( |i| = p \) or as

\[
i = -p \quad (34-2) \quad \text{(plane mirror)}.
\]

Only rays that are fairly close together can enter the eye after reflection at a mirror. For the eye position shown in Fig. 34-4, only a small portion of the mirror near point \( a \) (a portion smaller than the pupil of the eye) is useful in forming the image. To find this portion, close one eye and look at the mirror image of a small object such as the tip of a pencil. Then move your fingertip over the mirror surface until you cannot see the image. Only that small portion of the mirror under your fingertip produced the image.

**Extended Objects**

In Fig. 34-5, an extended object \( O \), represented by an upright arrow, is at perpendicular distance \( p \) in front of a plane mirror. Each small portion of the

---

**In a plane mirror the light seems to come from an object on the other side.**

**Figure 34-2** A point source of light \( O \), called the object, is a perpendicular distance \( p \) in front of a plane mirror. Light rays reaching the mirror from \( O \) reflect from the mirror. If your eye intercepts some of the reflected rays, you perceive a point source of light \( I \) to be behind the mirror, at a perpendicular distance \( i \). The perceived source \( I \) is a virtual image of object \( O \).

**Figure 34-3** Two rays from Fig. 34-2. Ray \( Oa \) makes an arbitrary angle \( \theta \) with the normal to the mirror surface. Ray \( Ob \) is perpendicular to the mirror.

**Figure 34-4** A “pencil” of rays from \( O \) enters the eye after reflection at the mirror. Only a small portion of the mirror near \( a \) is involved in this reflection. The light appears to originate at point \( I \) behind the mirror.

**Figure 34-5** An extended object \( O \) and its virtual image \( I \) in a plane mirror.
object that faces the mirror acts like the point source $O$ of Figs. 34-2 and 34-3. If you intercept the light reflected by the mirror, you perceive a virtual image $I$ that is a composite of the virtual point images of all those portions of the object. This virtual image seems to be at (negative) distance $i$ behind the mirror, with $i$ and $p$ related by Eq. 34-2.

We can also locate the image of an extended object as we did for a point object in Fig. 34-2: we draw some of the rays that reach the mirror from the top of the object, draw the corresponding reflected rays, and then extend those reflected rays behind the mirror until they intersect to form an image of the top of the object. We then do the same for rays from the bottom of the object. As shown in Fig. 34-5, we find that virtual image $I$ has the same orientation and height (measured parallel to the mirror) as object $O$.

**Mirror Maze**

In a mirror maze (Fig. 34-6), each wall is covered, floor to ceiling, with a mirror. Walk through such a maze and what you see in most directions is a confusing montage of reflections. In some directions, however, you see a hallway that seems to offer a path through the maze. Take these hallways, though, and you soon learn, after smacking into mirror after mirror, that the hallways are largely an illusion.

Figure 34-7a is an overhead view of a simple mirror maze in which differently painted floor sections form equilateral triangles ($60^\circ$ angles) and walls are covered with vertical mirrors. You look into the maze while standing at point $O$ at the middle of the maze entrance. In most directions, you see a confusing jumble of images. However, you see something curious in the direction of the ray shown in Fig. 34-7a. That ray leaves the middle of mirror $B$ and reflects to you at the middle of mirror $A$. (The reflection obeys the law of reflection, with the angle of incidence and the angle of reflection both equal to $30^\circ$.)

To make sense of the origin of the ray reaching you, your brain automatically extends the ray backward. It appears to originate at a point lying behind mirror $A$. That is, you perceive a virtual image of $B$ behind $A$, at a distance equal to the actual distance between $A$ and $B$ (Fig. 34-7b). Thus, when you face into the maze in this direction, you see $B$ along an apparent straight hallway consisting of four triangular floor sections.

This story is incomplete, however, because the ray reaching you does not originate at mirror $B$—it only reflects there. To find the origin, we continue to apply the law of reflection as we work backwards, reflection by reflection on the mirrors (Fig. 34-7c). We finally come to the origin of the ray: you! What you see when you look along the apparent hallway is a virtual image of yourself, at a distance of nine triangular floor sections from you (Fig. 34-7d).
Checkpoint 1

In the figure you are in a system of two vertical parallel mirrors $A$ and $B$ separated by distance $d$. A grinning gargoyle is perched at point $O$, a distance $0.2d$ from mirror $A$. Each mirror produces a first (least deep) image of the gargoyle. Then each mirror produces a second image with the object being the first image in the opposite mirror. Then each mirror produces a third image with the object being the second image in the opposite mirror, and so on—you might see hundreds of grinning gargoyle images. How deep behind mirror $A$ are the first, second, and third images in mirror $A$?
Spherical Mirrors

We turn now from images produced by plane mirrors to images produced by mirrors with curved surfaces. In particular, we consider spherical mirrors, which are simply mirrors in the shape of a small section of the surface of a sphere. A plane mirror is in fact a spherical mirror with an infinitely large radius of curvature and thus an approximately flat surface.

Making a Spherical Mirror

We start with the plane mirror of Fig. 34-8a, which faces leftward toward an object $O$ that is shown and an observer that is not shown. We make a concave mirror by curving the mirror’s surface so it is concave (“caved in”) as in Fig. 34-8b. Curving the surface in this way changes several characteristics of the mirror and the image it produces of the object:

1. The center of curvature $C$ (the center of the sphere of which the mirror’s surface is part) was infinitely far from the plane mirror; it is now closer but still in front of the concave mirror.
2. The field of view—the extent of the scene that is reflected to the observer—was wide; it is now smaller.
3. The image of the object was as far behind the plane mirror as the object was in front; the image is farther behind the concave mirror; that is, $|i|$ is greater.
4. The height of the image was equal to the height of the object; the height of the image is now greater. This feature is why many makeup mirrors and shaving mirrors are concave—they produce a larger image of a face.

We can make a convex mirror by curving a plane mirror so its surface is convex (“flexed out”) as in Fig. 34-8c. Curving the surface in this way (1) moves the center of curvature $C$ to behind the mirror and (2) increases the field of view. It also (3) moves the image of the object closer to the mirror and (4) shrinks it. Store surveillance mirrors are usually convex to take advantage of the increase in the field of view—more of the store can then be seen with a single mirror.

Focal Points of Spherical Mirrors

For a plane mirror, the magnitude of the image distance $i$ is always equal to the object distance $p$. Before we can determine how these two distances are related for a spherical mirror, we must consider the reflection of light from an object $O$ located an effectively infinite distance in front of a spherical mirror, on the mirror’s central axis. That axis extends through the center of curvature $C$ and the center $c$ of the mirror. Because of the great distance between the object and the mirror, the light waves spreading from the object are plane waves when they reach the mirror along the central axis. This means that the rays representing the light waves are all parallel to the central axis when they reach the mirror.

*Forming a Focus.* When these parallel rays reach a concave mirror like that of Fig. 34-9a, those near the central axis are reflected through a common point $F$; two of these reflected rays are shown in the figure. If we placed a (small) card at $F$, a point image of the infinitely distant object $O$ would appear on the card. (This would occur for any infinitely distant object.) Point $F$ is called the focal point (or focus) of the mirror, and its distance from the center of the mirror $c$ is the focal length $f$ of the mirror.

If we now substitute a convex mirror for the concave mirror, we find that the parallel rays are no longer reflected through a common point. Instead, they diverge as shown in Fig. 34-9b. However, if your eye intercepts some of the reflected light, you perceive the light as originating from a point source behind the mirror. This perceived source is located where extensions of the reflected rays pass through a common point ($F$ in Fig. 34-9b). That point is the focal point (or...
Focus of the convex mirror, and its distance from the mirror surface is the focal length \( f \) of the mirror. If we placed a card at this focal point, an image of object \( O \) would not appear on the card; so this focal point is not like that of a concave mirror.

**Two Types.** To distinguish the actual focal point of a concave mirror from the perceived focal point of a convex mirror, the former is said to be a real focal point and the latter is said to be a virtual focal point. Moreover, the focal length \( f \) of a concave mirror is taken to be a positive quantity, and that of a convex mirror a negative quantity. For mirrors of both types, the focal length \( f \) is related to the radius of curvature \( r \) of the mirror by

\[
f = \frac{1}{2}r \quad \text{(spherical mirror)},
\]

where \( r \) is positive for a concave mirror and negative for a convex mirror.

**Images from Spherical Mirrors**

**Inside.** With the focal point of a spherical mirror defined, we can find the relation between image distance \( i \) and object distance \( p \) for concave and convex spherical mirrors. We begin by placing the object \( O \) inside the focal point of the concave mirror—that is, between the mirror and its focal point \( F \) (Fig. 34-10a).
An observer can then see a virtual image of \( O \) in the mirror: The image appears to be behind the mirror, and it has the same orientation as the object.

If we now move the object away from the mirror until it is at the focal point, the image moves farther and farther back from the mirror until, when the object is at the focal point, the image is at infinity (Fig. 34-10b). The image is then ambiguous and imperceptible because neither the rays reflected by the mirror nor the ray extensions behind the mirror cross to form an image of \( O \).

**Outside.** If we next move the object outside the focal point—that is, farther away from the mirror than the focal point—the rays reflected by the mirror converge to form an **inverted** image of object \( O \) (Fig. 34-10c) in front of the mirror. That image moves in from infinity as we move the object farther outside \( F \). If you were to hold a card at the position of the image, the image would show up on the card—the image is said to be **focused** on the card by the mirror. (The verb “focus,” which in this context means to produce an image, differs from the noun “focus,” which is another name for the focal point.) Because this image can actually appear on a surface, it is a real image—the rays actually intersect to create the image, regardless of whether an observer is present. The image distance \( i \) of a real image is a positive quantity, in contrast to that for a virtual image. We can now generalize about the location of images from spherical mirrors:

Real images form on the side of a mirror where the object is, and virtual images form on the opposite side.

**Main Equation.** As we shall prove in Module 34-6, when light rays from an object make only small angles with the central axis of a spherical mirror, a simple equation relates the object distance \( p \), the image distance \( i \), and the focal length \( f \):

\[
\frac{1}{p} + \frac{1}{i} = \frac{1}{f} \quad \text{(spherical mirror).} \tag{34-4}
\]

We assume such small angles in figures such as Fig. 34-10, but for clarity the rays are drawn with exaggerated angles. With that assumption, Eq. 34-4 applies to any concave, convex, or plane mirror. For a convex or plane mirror, only a virtual image can be formed, regardless of the object’s location on the central axis. As shown in the example of a convex mirror in Fig. 34-8c, the image is always on the opposite side of the mirror from the object and has the same orientation as the object.

**Magnification.** The size of an object or image, as measured **perpendicular** to the mirror’s central axis, is called the object or image **height**. Let \( h \) represent the height of the object, and \( h' \) the height of the image. Then the ratio \( h'/h \) is called the **lateral magnification** \( m \) produced by the mirror. However, by convention, the lateral magnification always includes a plus sign when the image orientation is that of the object and a minus sign when the image orientation is opposite that of the object. For this reason, we write the formula for \( m \) as

\[
|m| \cdot \frac{h'}{h} \quad \text{(lateral magnification).} \tag{34-5}
\]

We shall soon prove that the lateral magnification can also be written as

\[
m = -\frac{i}{p} \quad \text{(lateral magnification).} \tag{34-6}
\]

For a plane mirror, for which \( i = -p \), we have \( m = +1 \). The magnification of 1 means that the image is the same size as the object. The plus sign means that
the image and the object have the same orientation. For the concave mirror of Fig. 34-10c, $m = -1.5$.

**Organizing Table.** Equations 34-3 through 34-6 hold for all plane mirrors, concave spherical mirrors, and convex spherical mirrors. In addition to those equations, you have been asked to absorb a lot of information about these mirrors, and you should organize it for yourself by filling in Table 34-1. Under Image Location, note whether the image is on the same side of the mirror as the object or on the opposite side. Under Image Type, note whether the image is real or virtual. Under Image Orientation, note whether the image has the same orientation as the object or is inverted. Under Sign, give the sign of the quantity or fill in ± if the sign is ambiguous. You will need this organization to tackle homework or a test.

**Locating Images by Drawing Rays**

Figures 34-11a and b show an object $O$ in front of a concave mirror. We can graphically locate the image of any off-axis point of the object by drawing a *ray diagram* with any two of four special rays through the point:

![Ray diagrams](image-url)
1. A ray that is initially parallel to the central axis reflects through the focal point \( F \) (ray 1 in Fig. 34-11a).

2. A ray that reflects from the mirror after passing through the focal point emerges parallel to the central axis (ray 2 in Fig. 34-11a).

3. A ray that reflects from the mirror after passing through the center of curvature \( C \) returns along itself (ray 3 in Fig. 34-11b).

4. A ray that reflects from the mirror at point \( c \) is reflected symmetrically about that axis (ray 4 in Fig. 34-11b).

The image of the point is at the intersection of the two special rays you choose. The image of the object can then be found by locating the images of two or more of its off-axis points (say, the point most off axis) and then sketching in the rest of the image. You need to modify the descriptions of the rays slightly to apply them to convex mirrors, as in Figs. 34-11c and d.

**Proof of Equation 34-6**

We are now in a position to derive Eq. 34-6 \((m = -i/p)\), the equation for the lateral magnification of an object reflected in a mirror. Consider ray 4 in Fig. 34-11b. It is reflected at point \( c \) so that the incident and reflected rays make equal angles with the axis of the mirror at that point.

The two right triangles \( abc \) and \( dec \) in the figure are similar (have the same set of angles); so we can write

\[
\frac{de}{ab} = \frac{cd}{ca}
\]

The quantity on the left (apart from the question of sign) is the lateral magnification \( m \) produced by the mirror. Because we indicate an inverted image as a *negative* magnification, we symbolize this as \(-m\). However, \( cd = i \) and \( ca = p \); so we have

\[
m = -\frac{i}{p} \quad \text{(magnification),} \quad (34-7)
\]

which is the relation we set out to prove.

**Checkpoint 2**

A Central American vampire bat, dozing on the central axis of a spherical mirror, is magnified by \( m = -4 \). Is its image (a) real or virtual, (b) inverted or of the same orientation as the bat, and (c) on the same side of the mirror as the bat or on the opposite side?

**Sample Problem 34.01 Image produced by a spherical mirror**

A tarantula of height \( h \) sits cautiously before a spherical mirror whose focal length has absolute value \(|f| = 40 \text{ cm}\). The image of the tarantula produced by the mirror has the same orientation as the tarantula and has height \( h' = 0.20h \).

(a) Is the image real or virtual, and is it on the same side of the mirror as the tarantula or the opposite side?

**Reasoning:** Because the image has the same orientation as the tarantula (the object), it must be virtual and on the opposite side of the mirror. (You can easily see this result if you have filled out Table 34-1.)

(b) Is the mirror concave or convex, and what is its focal length \( f \), sign included?

**KEY IDEA**

We cannot tell the type of mirror from the type of image because both types of mirror can produce virtual images. Similarly, we cannot tell the type of mirror from the sign of the focal length \( f \), as obtained from Eq. 34-3 or Eq. 34-4, because we lack enough information to use either equation. However, we can make use of the magnification information.
34-3 SPHERICAL REFRACTING SURFACES

Learning Objectives

After reading this module, you should be able to . . .

34.18 Identify that the refraction of rays by a spherical surface can produce real images and virtual images of an object, depending on the indexes of refraction on the two sides, the surface’s radius of curvature \( r \), and whether the object faces a concave or convex surface.

34.19 For a point object on the central axis of a spherical refracting surface, sketch the refraction of a ray in the six general arrangements and identify whether the image is real or virtual.

34.20 For a spherical refracting surface, identify what type of image appears on the same side as the object and what type appears on the opposite side.

34.21 For a spherical refracting surface, apply the relationship between the two indexes of refraction, the object distance \( p \), the image distance \( i \), and the radius of curvature \( r \).

34.22 Identify the algebraic signs of the radius \( r \) for an object facing a concave refracting surface and a convex refracting surface.

Key Ideas

- A single spherical surface that refracts light can form an image.
- The object distance \( p \), the image distance \( i \), and the radius of curvature \( r \) of the surface are related by

\[
\frac{n_1}{p} + \frac{n_2}{i} = \frac{n_2 - n_1}{r},
\]

where \( n_1 \) is the index of refraction of the material where the object is located and \( n_2 \) is the index of refraction on the other side of the surface.

- If the surface faced by the object is convex, \( r \) is positive, and if it is concave, \( r \) is negative.
- Images on the object’s side of the surface are virtual, and images on the opposite side are real.

Spherical Refracting Surfaces

We now turn from images formed by reflection to images formed by refraction through surfaces of transparent materials, such as glass. We shall consider only spherical surfaces, with radius of curvature \( r \) and center of curvature \( C \). The light will be emitted by a point object \( O \) in a medium with index of refraction \( n_1 \); it will refract through a spherical surface into a medium of index of refraction \( n_2 \).

Our concern is whether the light rays, after refracting through the surface, form a real image (no observer necessary) or a virtual image (assuming that an
observer intercepts the rays). The answer depends on the relative values of $n_1$ and $n_2$ and on the geometry of the situation.

Six possible results are shown in Fig. 34-12. In each part of the figure, the medium with the greater index of refraction is shaded, and object $O$ is always in the medium with index of refraction $n_1$, to the left of the refracting surface. In each part, a representative ray is shown refracting through the surface. (That ray and a ray along the central axis suffice to determine the position of the image in each case.)

At the point of refraction of each ray, the normal to the refracting surface is a radial line through the center of curvature $C$. Because of the refraction, the ray bends toward the normal if it is entering a medium of greater index of refraction and away from the normal if it is entering a medium of lesser index of refraction. If the bending sends the ray toward the central axis, that ray and others (undrawn) form a real image on that axis. If the bending sends the ray away from the central axis, the ray cannot form a real image; however, backward extensions of it and other refracted rays can form a virtual image, provided (as with mirrors) some of those rays are intercepted by an observer.

Real images $I$ are formed (at image distance $i$) in parts $a$ and $b$ of Fig. 34-12, where the refraction directs the ray toward the central axis. Virtual images are formed in parts $c$ and $d$, where the refraction directs the ray away from the central axis. Note, in these four parts, that real images are formed when the object is relatively far from the refracting surface and virtual images are formed when the object is nearer the refracting surface. In the final situations (Figs. 34-12e and f), refraction always directs the ray away from the central axis and virtual images are always formed, regardless of the object distance.

Note the following major difference from reflected images:

Real images form on the side of a refracting surface that is opposite the object, and virtual images form on the same side as the object.

---

**Figure 34-12** Six possible ways in which an image can be formed by refraction through a spherical surface of radius $r$ and center of curvature $C$. The surface separates a medium with index of refraction $n_1$ from a medium with index of refraction $n_2$. The point object $O$ is always in the medium with $n_1$, to the left of the surface. The material with the lesser index of refraction is unshaded (think of it as being air, and the other material as being glass). Real images are formed in $(a)$ and $(b)$; virtual images are formed in the other four situations.
In Module 34-6, we shall show that (for light rays making only small angles with the central axis)

\[ \frac{n_1}{p} + \frac{n_2}{i} = \frac{n_2 - n_1}{r}. \]  

(34-8)

Just as with mirrors, the object distance \( p \) is positive, and the image distance \( i \) is positive for a real image and negative for a virtual image. However, to keep all the signs correct in Eq. 34-8, we must use the following rule for the sign of the radius of curvature \( r \):

When the object faces a convex refracting surface, the radius of curvature \( r \) is positive. When it faces a concave surface, \( r \) is negative.

Be careful: This is just the reverse of the sign convention we have for mirrors, which can be a slippery point in the heat of an exam.

**Sample Problem 34.02 Image produced by a refracting surface**

A Jurassic mosquito is discovered embedded in a chunk of amber, which has index of refraction 1.6. One surface of the amber is spherically convex with radius of curvature 3.0 mm (Fig. 34-13). The mosquito’s head happens to be on the central axis of that surface and, when viewed along the axis, appears to be buried 5.0 mm into the amber. How deep is it really?

**KEY IDEAS**

The head appears to be 5.0 mm into the amber only because the light rays that the observer intercepts are bent by refraction at the convex amber surface. The image distance \( i \) differs from the object distance \( p \) according to Eq. 34-8. To use that equation to find the object distance, we first note:

1. Because the object (the head) and its image are on the same side of the refracting surface, the image must be virtual and so \( i = -5.0 \) mm.
2. Because the object is always taken to be in the medium of index of refraction \( n_1 \), we must have \( n_1 = 1.6 \) and \( n_2 = 1.0 \).
3. Because the object faces a concave refracting surface, the radius of curvature \( r \) is negative, and so \( r = -3.0 \) mm.

**Calculations:** Making these substitutions in Eq. 34-8,

\[ \frac{1.6}{p} + \frac{1.0}{-5.0 \text{ mm}} = \frac{1.0 - 1.6}{-3.0 \text{ mm}} \]

yields

\[ \frac{p}{-5.0 \text{ mm}} = \frac{1.0}{-3.0 \text{ mm}} \]

and

\[ p = 4.0 \text{ mm}. \]  

(Answer)

Figure 34-13 A piece of amber with a mosquito from the Jurassic period, with the head buried at point \( O \). The spherical refracting surface at the right end, with center of curvature \( C \), provides an image \( I \) to an observer intercepting rays from the object at \( O \).
34-4  **THIN LENSES**

**Learning Objectives**

*After reading this module, you should be able to . . .*

34.23  Distinguish converging lenses from diverging lenses.
34.24  For converging and diverging lenses, sketch a ray diagram for rays initially parallel to the central axis, indicating how they form focal points, and identifying which is real and which is virtual.
34.25  Distinguish a real focal point from a virtual focal point, identify which corresponds to which type of lens and under which circumstances, and identify the algebraic sign associated with each focal length.
34.26  For an object (a) inside and (b) outside the focal point of a converging lens, sketch at least two rays to find the image and identify the type and orientation of the image.
34.27  For a converging lens, distinguish the locations and orientations of a real image and a virtual image.
34.28  For an object in front of a diverging lens, sketch at least two rays to find the image and identify the type and orientation of the image.
34.29  Identify which type of lens can produce both real and virtual images and which type can produce only virtual images.
34.30  Identify the algebraic sign of the image distance $i$ for a real image and for a virtual image.
34.31  For converging and diverging lenses, apply the relationship between the focal length $f$, object distance $p$, and image distance $i$.
34.32  Apply the relationships between lateral magnification $m$, image height $h'$, object height $h$, image distance $i$, and object distance $p$.
34.33  Apply the lens maker's equation to relate a focal length to the index of refraction of a lens (assumed to be in air) and the radii of curvature of the two sides of the lens.
34.34  For a multiple-lens system with the object in front of lens 1, find the image produced by lens 1 and then use it as the object for lens 2, and so on.
34.35  For a multiple-lens system, determine the overall magnification (of the final image) from the magnifications produced by each lens.

**Key Ideas**

- This module primarily considers thin lenses with symmetric, spherical surfaces.
- If parallel rays are sent through a converging lens parallel to the central axis, the refracted rays pass through a common point (a real focus $F$) at a focal distance $f$ (a positive quantity) from the lens. If they are sent through a diverging lens, backward extensions of the refracted rays pass through a common point (a virtual focus $F$) at a focal distance $f$ (a negative quantity) from the lens.
- A converging lens can form a real image (if the object is outside the focal point) or a virtual image (if the object is inside the focal point).
- A diverging lens can form only a virtual image.
- For an object in front of a lens, object distance $p$ and image distance $i$ are related to the lens’s focal length $f$, index of refraction $n$, and radii of curvature $r_1$ and $r_2$ by

$$\frac{1}{p} + \frac{1}{i} = \frac{1}{f} = \left(n - 1\right)\left(\frac{1}{r_1} - \frac{1}{r_2}\right).$$

- The magnitude of the lateral magnification $m$ of an object is the ratio of the image height $h'$ to object height $h$,

$$|m| = \frac{h'}{h},$$

and is related to the object distance $p$ and image distance $i$ by

$$m = \frac{i}{p}.$$

- For a system of lenses with a common central axis, the image produced by the first lens acts as the object for the second lens, and so on, and the overall magnification is the product of the individual magnifications.

**Thin Lenses**

A **lens** is a transparent object with two refracting surfaces whose central axes coincide. The common central axis is the central axis of the lens. When a lens is surrounded by air, light refracts from the air into the lens, crosses through the lens, and then refracts back into the air. Each refraction can change the direction of travel of the light.

A lens that causes light rays initially parallel to the central axis to converge is (reasonably) called a **converging lens**. If, instead, it causes such rays to diverge, the lens is a **diverging lens**. When an object is placed in front of a lens of either type, light rays from the object that refract into and out of the lens can produce an image of the object.
Lens Equations. We shall consider only the special case of a thin lens—that is, a lens in which the thickest part is thin relative to the object distance \( p \), the image distance \( i \), and the radii of curvature \( r_1 \) and \( r_2 \) of the two surfaces of the lens. We shall also consider only light rays that make small angles with the central axis (they are exaggerated in the figures here). In Module 34-6 we shall prove that for such rays, a thin lens has a focal length \( f \). Moreover, \( i \) and \( p \) are related to each other by

\[
\frac{1}{f} = \frac{1}{p} + \frac{1}{i} \quad \text{(thin lens),} \tag{34-9}
\]

which is the same as we had for mirrors. We shall also prove that when a thin lens with index of refraction \( n \) is surrounded by air, this focal length \( f \) is given by

\[
\frac{1}{f} = (n - 1) \left( \frac{1}{r_1} - \frac{1}{r_2} \right) \quad \text{(thin lens in air),} \tag{34-10}
\]

which is often called the lens maker's equation. Here \( r_1 \) is the radius of curvature of the lens surface nearer the object and \( r_2 \) is that of the other surface. The signs of these radii are found with the rules in Module 34-3 for the radii of spherical refracting surfaces. If the lens is surrounded by some medium other than air (say, corn oil) with index of refraction \( n_{\text{medium}} \), we replace \( n \) in Eq. 34-10 with \( n/n_{\text{medium}} \). Keep in mind the basis of Eqs. 34-9 and 34-10:

A lens can produce an image of an object only because the lens can bend light rays, but it can bend light rays only if its index of refraction differs from that of the surrounding medium.

Forming a Focus. Figure 34-14a shows a thin lens with convex refracting surfaces, or sides. When rays that are parallel to the central axis of the lens are sent through the lens, they refract twice, as is shown enlarged in Fig. 34-14b. This

**Figure 34-14** (a) Rays initially parallel to the central axis of a converging lens are made to converge to a real focal point \( F_2 \) by the lens. The lens is thinner than drawn, with a width like that of the vertical line through it. We shall consider all the bending of rays as occurring at this central line. (b) An enlargement of the top part of the lens of (a); normals to the surfaces are shown dashed. Note that both refractions bend the ray downward, toward the central axis. (c) The same initially parallel rays are made to diverge by a diverging lens. Extensions of the diverging rays pass through a virtual focal point \( F_2 \). (d) An enlargement of the top part of the lens of (c). Note that both refractions bend the ray upward, away from the central axis.

To find the focus, send in rays parallel to the central axis.

The bending occurs only at the surfaces.

If you intercept these rays, they seem to come from \( F_2 \).
double refraction causes the rays to converge and pass through a common point $F_2$ at a distance $f$ from the center of the lens. Hence, this lens is a converging lens; further, a real focal point (or focus) exists at $F_1$ (because the rays really do pass through it), and the associated focal length is $f$. When rays parallel to the central axis are sent in the opposite direction through the lens, we find another real focal point at $F_1$ on the other side of the lens. For a thin lens, these two focal points are equidistant from the lens.

**Signs, Signs, Signs.** Because the focal points of a converging lens are real, we take the associated focal lengths $f$ to be positive, just as we do with a real focus of a concave mirror. However, signs in optics can be tricky; so we had better check this in Eq. 34-10. The left side of that equation is positive if $f$ is positive; how about the right side? We examine it term by term. Because the index of refraction $n$ of glass or any other material is greater than 1, the term $(n-1)$ must be positive. Because the source of the light (which is the object) is at the left and faces the convex left side of the lens, the radius of curvature $r_1$ of that side must be positive according to the sign rule for refracting surfaces. Similarly, because the object faces a concave right side of the lens, the radius of curvature $r_2$ of that side must be negative according to that rule. Thus, the term $(1/r_1 - 1/r_2)$ is positive, the whole right side of Eq. 34-10 is positive, and all the signs are consistent.

Figure 34-14c shows a thin lens with concave sides. When rays that are parallel to the central axis of the lens are sent through this lens, they refract twice, as is shown enlarged in Fig. 34-14d; these rays diverge, never passing through any common point, and so this lens is a diverging lens. However, extensions of the rays do pass through a common point $F_2$ at a distance $f$ from the center of the lens. Hence, the lens has a virtual focal point at $F_2$. (If your eye intercepts some of the diverging rays, you perceive a bright spot to be at $F_2$, as if it is the source of the light.) Another virtual focus exists on the opposite side of the lens at $F_1$, symmetrically placed if the lens is thin. Because the focal points of a diverging lens are virtual, we take the focal length $f$ to be negative.

**Images from Thin Lenses**

We now consider the types of image formed by converging and diverging lenses. Figure 34-15a shows an object $O$ outside the focal point $F_1$ of a converging lens. The two rays drawn in the figure show that the lens forms a real, inverted image $I$ of the object on the side of the lens opposite the object.

When the object is placed inside the focal point $F_1$, as in Fig. 34-15b, the lens forms a virtual image $I$ on the same side of the lens as the object and with the same orientation. Hence, a converging lens can form either a real image or a virtual image, depending on whether the object is inside or outside the focal point, respectively.

Figure 34-15c shows an object $O$ in front of a diverging lens. Regardless of the object distance (regardless of whether $O$ is inside or outside the virtual focal point), this lens produces a virtual image that is on the same side of the lens as the object and has the same orientation.

As with mirrors, we take the image distance $i$ to be positive when the image is real and negative when the image is virtual. However, the locations of real and virtual images from lenses are the reverse of those from mirrors:

- Real images form on the side of a lens that is opposite the object, and virtual images form on the side where the object is.

The lateral magnification $m$ produced by converging and diverging lenses is given by Eqs. 34-5 and 34-6, the same as for mirrors.

You have been asked to absorb a lot of information in this module, and you should organize it for yourself by filling in Table 34-2 for thin symmetric lenses (both...

Locating Images of Extended Objects by Drawing Rays

Figure 34-16a shows an object \( O \) outside focal point \( F_1 \) of a converging lens. We can graphically locate the image of any off-axis point on such an object (such as the tip of the arrow in Fig. 34-16a) by drawing a ray diagram with any two of three special rays through the point. These special rays, chosen from all those that pass through the lens to form the image, are the following:

1. A ray that is initially parallel to the central axis of the lens will pass through focal point \( F_2 \) (ray 1 in Fig. 34-16a).
2. A ray that initially passes through focal point \( F_1 \) will emerge from the lens parallel to the central axis (ray 2 in Fig. 34-16a).
3. A ray that is initially directed toward the center of the lens will emerge from the lens with no change in its direction (ray 3 in Fig. 34-16a) because the ray encounters the two sides of the lens where they are almost parallel.

The image of the point is located where the rays intersect on the far side of the lens. The image of the object is found by locating the images of two or more of its points.

Figure 34-16b shows how the extensions of the three special rays can be used to locate the image of an object placed inside focal point \( F_1 \) of a converging lens. Note that the description of ray 2 requires modification (it is now a ray whose backward extension passes through \( F_1 \)).

You need to modify the descriptions of rays 1 and 2 to use them to locate an image placed (anywhere) in front of a diverging lens. In Fig. 34-16c, for example, we find the point where ray 3 intersects the backward extensions of rays 1 and 2.

In each figure, any two of the rays will locate the image.

Figure 34-16 Three special rays allow us to locate an image formed by a thin lens whether the object \( O \) is (a) outside or (b) inside the focal point of a converging lens, or (c) anywhere in front of a diverging lens.
Two-Lens Systems
Here we consider an object sitting in front of a system of two lenses whose central axes coincide. Some of the possible two-lens systems are sketched in Fig. 34-17, but the figures are not drawn to scale. In each, the object sits to the left of lens 1 but can be inside or outside the focal point of the lens. Although tracing the light rays through any such two-lens system can be challenging, we can use the following simple two-step solution:

**Step 1** Neglecting lens 2, use Eq. 34-9 to locate the image $I_1$ produced by lens 1. Determine whether the image is on the left or right side of the lens, whether it is real or virtual, and whether it has the same orientation as the object. Roughly sketch $I_1$. The top part of Fig. 34-17a gives an example.
The object must be outside the focal point (the only way a real image can be produced). Also, the image is inverted and on the side of the lens opposite the object. (That is how a converging lens makes a real image.)

(b) What are the two radii of curvature of the lens?

KEY IDEAS

1. Because the lens is symmetric, \( r_1 \) (for the surface nearer the object) and \( r_2 \) have the same magnitude \( r \).
2. Because the lens is a converging lens, the object faces a convex surface on the nearer side and so \( r_1 = +r \). Similarly, it faces a concave surface on the farther side; so \( r_2 = -r \).
3. We can relate these radii of curvature to the focal length \( f \) via the lens maker’s equation, Eq. 34-10 (our only equation involving the radii of curvature of a lens).
4. We can relate \( f \) to the object distance \( p \) and image distance \( i \) via Eq. 34-9.
Calculations: We know \( p \), but we do not know \( i \). Thus, our starting point is to finish the calculation for \( i \) in part (a); we obtain
\[
i = (0.25)(20 \text{ cm}) = 5.0 \text{ cm}.
\]
Now Eq. 34-9 gives us
\[
\frac{1}{f} = \frac{1}{p} + \frac{1}{i} = \frac{1}{20 \text{ cm}} + \frac{1}{5.0 \text{ cm}},
\]
from which we find \( f = 4.0 \text{ cm} \).

Sample Problem 34.04 Image produced by a system of two thin lenses

Figure 34-18a shows a jalapeño seed \( O_1 \) that is placed in front of two thin symmetrical coaxial lenses 1 and 2, with focal lengths \( f_1 = +24 \text{ cm} \) and \( f_2 = +9.0 \text{ cm} \), respectively, and with lens separation \( L = 10 \text{ cm} \). The seed is 6.0 cm from lens 1. Where does the system of two lenses produce an image of the seed?

KEY IDEA

We could locate the image produced by the system of lenses by tracing light rays from the seed through the two lenses. However, we can, instead, calculate the location of that image by working through the system in steps, lens by lens. We begin with the lens closer to the seed. The image we seek is the final one — that is, image \( I_2 \) produced by lens 2.

Lens 1: Ignoring lens 2, we locate the image \( I_1 \) produced by lens 1 by applying Eq. 34-9 to lens 1 alone:
\[
\frac{1}{p_1} + \frac{1}{i_1} = \frac{1}{f_1}
\]
The object \( O_1 \) for lens 1 is the seed, which is 6.0 cm from the lens; thus, we substitute \( p_1 = +6.0 \text{ cm} \). Also substituting the given value of \( f_1 \), we then have
\[
\frac{1}{+6.0 \text{ cm}} + \frac{1}{i_1} = \frac{1}{+24 \text{ cm}}
\]
which yields \( i_1 = -8.0 \text{ cm} \).

This tells us that image \( I_1 \) is 8.0 cm from lens 1 and virtual. (We could have guessed that it is virtual by noting that the seed is inside the focal point of lens 1, that is, between the lens and its focal point.) Because \( I_1 \) is virtual, it is on the same side of the lens as object \( O_1 \) and has the same orientation as the seed, as shown in Fig. 34-18b.

Lens 2: In the second step of our solution, we treat image \( I_1 \) as an object \( O_2 \) for the second lens and now ignore lens 1. We first note that this object \( O_2 \) is outside the focal point

Equation 34-10 then gives us
\[
\frac{1}{f} = (n - 1) \left( \frac{1}{r_1} - \frac{1}{r_2} \right) = (n - 1) \left( \frac{1}{+r} - \frac{1}{-r} \right)
\]
or, with known values inserted,
\[
\frac{1}{4.0 \text{ cm}} = (1.65 - 1) \frac{2}{r}
\]
which yields
\[
r = (0.65)(2)(4.0 \text{ cm}) = 5.2 \text{ cm}.
\]
(Answer)
The human eye is a remarkably effective organ, but its range can be extended in many ways by optical instruments such as eyeglasses, microscopes, and telescopes. Many such devices extend the scope of our vision beyond the visible range; satellite-borne infrared cameras and x-ray microscopes are just two examples.

The mirror and thin-lens formulas can be applied only as approximations to most sophisticated optical instruments. The lenses in typical laboratory microscopes are by no means “thin.” In most optical instruments the lenses are compound lenses; that is, they are made of several components, the interfaces rarely being exactly spherical. Now we discuss three optical instruments, assuming, for simplicity, that the thin-lens formulas apply.

The angular magnification of a simple magnifying lens is

\[ m = \frac{25 \text{ cm}}{f}, \]

where \( f \) is the focal length of the lens and 25 cm is a reference value for the near point value.

The overall magnification of a compound microscope is due to the lateral magnification by the objective and the angular magnification by the eyepiece.

The overall magnification of a compound microscope is

\[ M = mm_\theta = -\frac{s}{f_{ob}} \frac{25 \text{ cm}}{f_{ey}}, \]

where \( m \) is the lateral magnification of the objective, \( m_\theta \) is the angular magnification of the eyepiece, \( s \) is the tube length, \( f_{ob} \) is the focal length of the objective, and \( f_{ey} \) is the focal length of the eyepiece.

The angular magnification of a refracting telescope is

\[ m_\theta = -\frac{f_{ob}}{f_{ey}}, \]

Key Ideas

- The angular magnification of a simple magnifying lens is

\[ m = \frac{25 \text{ cm}}{f}, \]

- The overall magnification of a compound microscope is

\[ M = mm_\theta = -\frac{s}{f_{ob}} \frac{25 \text{ cm}}{f_{ey}}, \]

- The angular magnification of a refracting telescope is

\[ m_\theta = -\frac{f_{ob}}{f_{ey}}, \]
To distant virtual image

**Figure 34-19** (a) An object \( O \) of height \( h \) placed at the near point of a human eye occupies angle \( \theta \) in the eye’s view. (b) The object is moved closer to increase the angle, but now the observer cannot bring the object into focus. (c) A converging lens is placed between the object and the eye, with the object just inside the focal point \( F_1 \) of the lens. The image produced by the lens is then far enough away to be focused by the eye, and the image occupies a larger angle \( \theta' \) than object \( O \) does in (a).

### Simple Magnifying Lens

The normal human eye can focus a sharp image of an object on the retina (at the rear of the eye) if the object is located anywhere from infinity to a certain point called the *near point* \( P_n \). If you move the object closer to the eye than the near point, the perceived retinal image becomes fuzzy. The location of the near point normally varies with age, generally moving away from the person. To find your own near point, remove your glasses or contacts if you wear any, close one eye, and then bring this page closer to your open eye until it becomes indistinct. In what follows, we take the near point to be 25 cm from the eye, a bit more than the typical value for 20-year-olds.

Figure 34-19a shows an object \( O \) placed at the near point \( P_n \) of an eye. The size of the image of the object produced on the retina depends on the angle \( \theta \) that the object occupies in the field of view from that eye. By moving the object closer to the eye, as in Fig. 34-19b, you can increase the angle and, hence, the possibility of distinguishing details of the object. However, because the object is then closer than the near point, it is no longer *in focus*; that is, the image is no longer clear.

You can restore the clarity by looking at \( O \) through a converging lens, placed so that \( O \) is just inside the focal point \( F_1 \) of the lens, which is at focal length \( f \) (Fig. 34-19c). What you then see is the virtual image of \( O \) produced by the lens. That image is farther away than the near point; thus, the eye can see it clearly.

Moreover, the angle \( \theta' \) occupied by the virtual image is larger than the largest angle \( \theta \) that the object alone can occupy and still be seen clearly. The *angular magnification* \( m_\theta \) (not to be confused with lateral magnification \( m \)) of what is seen is

\[
m_\theta = \frac{\theta'}{\theta}.
\]

In words, the angular magnification of a simple magnifying lens is a comparison of the angle occupied by the image the lens produces with the angle occupied by the object when the object is moved to the near point of the viewer.
From Fig. 34-19, assuming that \( O \) is at the focal point of the lens, and approximating \( \tan \theta \) as \( \theta \) and \( \tan \theta' \) as \( \theta' \) for small angles, we have

\[
\theta = \frac{h}{25 \text{ cm}} \quad \text{and} \quad \theta' = \frac{h}{f}.
\]

We then find that

\[
m_\theta \approx \frac{25 \text{ cm}}{f} \quad \text{(simple magnifier).} \quad (34-12)
\]

**Compound Microscope**

Figure 34-20 shows a thin-lens version of a compound microscope. The instrument consists of an objective (the front lens) of focal length \( f_{ob} \) and an eyepiece (the lens near the eye) of focal length \( f_{ey} \). It is used for viewing small objects that are very close to the objective.

The object \( O \) to be viewed is placed just outside the first focal point \( F_1 \) of the objective, close enough to \( F_1 \) that we can approximate its distance \( p \) from the lens as being \( f_{ob} \). The separation between the lenses is then adjusted so that the enlarged, inverted, real image \( I \) produced by the objective is located just inside the first focal point \( F'_1 \) of the eyepiece. The tube length \( s \) shown in Fig. 34-20 is actually large relative to \( f_{ob} \), and therefore we can approximate the distance \( i \) between the objective and the image \( I \) as being length \( s \).

From Eq. 34-6, and using our approximations for \( p \) and \( i \), we can write the lateral magnification produced by the objective as

\[
m = -\frac{i}{p} = -\frac{s}{f_{ob}}. \quad (34-13)
\]

Because the image \( I \) is located just inside the focal point \( F'_1 \) of the eyepiece, the eyepiece acts as a simple magnifying lens, and an observer sees a final (virtual, inverted) image \( I' \) through it. The overall magnification of the instrument is the product of the lateral magnification \( m \) produced by the objective, given by Eq. 34-13, and the angular magnification \( m_\theta \) produced by the eyepiece, given by Eq. 34-12; that is,

\[
M = mm_\theta = -\frac{s}{f_{ob}} \cdot \frac{25 \text{ cm}}{f_{cy}} \quad \text{(microscope).} \quad (34-14)
\]

**Refracting Telescope**

Telescopes come in a variety of forms. The form we describe here is the simple refracting telescope that consists of an objective and an eyepiece; both are represented in Fig. 34-21 with simple lenses, although in practice, as is also true for most microscopes, each lens is actually a compound lens system.
The lens arrangements for telescopes and for microscopes are similar, but telescopes are designed to view large objects, such as galaxies, stars, and planets, at large distances, whereas microscopes are designed for just the opposite purpose. This difference requires that in the telescope of Fig. 34-21 the second focal point of the objective \( F_2 \) coincide with the first focal point of the eyepiece \( F'_1 \), whereas in the microscope of Fig. 34-20 these points are separated by the tube length \( s \).

In Fig. 34-21a, parallel rays from a distant object strike the objective, making an angle \( \theta_{ob} \) with the telescope axis and forming a real, inverted image \( I \) at the common focal point \( F_2, F'_1 \). This image \( I \) acts as an object for the eyepiece, through which an observer sees a distant (still inverted) virtual image \( I' \). The rays defining the image make an angle \( \theta_{ey} \) with the telescope axis.

The angular magnification \( m_\theta \) of the telescope is \( \theta_{ey}/\theta_{ob} \). From Fig. 34-21b, for rays close to the central axis, we can write \( \theta_{ob} = h'/f_{ob} \) and \( \theta_{ey} = h'/f_{ey} \), which gives us

\[
m_\theta = -\frac{f_{ob}}{f_{ey}} \quad \text{(telescope)}, \tag{34-15}
\]

where the minus sign indicates that \( I' \) is inverted. In words, the angular magnification of a telescope is a comparison of the angle occupied by the image the telescope produces with the angle occupied by the distant object as seen without the telescope.

Magnification is only one of the design factors for an astronomical telescope and is indeed easily achieved. A good telescope needs light-gathering power, which determines how bright the image is. This is important for viewing faint objects such as distant galaxies and is accomplished by making the objective diameter as large as possible. A telescope also needs resolving power, which is the ability to distinguish between two distant objects (stars, say) whose angular separation is small. Field of view is another important design parameter. A telescope designed to look at galaxies (which occupy a tiny field of view) is much different from one designed to track meteors (which move over a wide field of view).

The telescope designer must also take into account the difference between real lenses and the ideal thin lenses we have discussed. A real lens with spherical surfaces does not form sharp images, a flaw called spherical aberration. Also, because refraction by the two surfaces of a real lens depends on wavelength, a real lens does not focus light of different wavelengths to the same point, a flaw called chromatic aberration.

This brief discussion by no means exhausts the design parameters of astronomical telescopes—many others are involved. We could make a similar listing for any other high-performance optical instrument.

---

### 34-6 THREE PROOFS

#### The Spherical Mirror Formula (Eq. 34-4)

Figure 34-22 shows a point object \( O \) placed on the central axis of a concave spherical mirror, outside its center of curvature \( C \). A ray from \( O \) that makes an angle \( \alpha \) with the axis intersects the axis at \( I \) after reflection from the mirror at \( a \). A ray that leaves \( O \) along the axis is reflected back along itself at \( c \) and also passes through \( I \). Thus, because both rays pass through that common point, \( I \) is the image of \( O \); it is a real image because light actually passes through it. Let us find the image distance \( i \).

![Figure 34-22](image-url)
A real point image \( I \) of a point object \( O \) is formed by refraction at a spherical convex surface between two media.

Figure 34-23 A real point image \( I \) of a point object \( O \) is formed by refraction at a spherical convex surface between two media.

A trigonometry theorem that is useful here tells us that an exterior angle of a triangle is equal to the sum of the two opposite interior angles. Applying this to triangles \( OaC \) and \( OaI \) in Fig. 34-22 yields

\[
\beta = \alpha + \theta \quad \text{and} \quad \gamma = \alpha + 2\theta.
\]

If we eliminate \( \theta \) between these two equations, we find

\[
\alpha + \gamma = 2\beta. \tag{34-16}
\]

We can write angles \( \alpha, \beta, \) and \( \gamma \), in radian measure, as

\[
\alpha = \frac{ac}{cO} = \frac{ac}{p}, \quad \beta = \frac{ac}{cC} = \frac{ac}{r},
\]

and

\[
\gamma = \frac{ac}{cI} = \frac{ac}{i}, \tag{34-17}
\]

where the overhead symbol means “arc.” Only the equation for \( \beta \) is exact, because the center of curvature of \( ac \) is at \( C \). However, the equations for \( \alpha \) and \( \gamma \) are approximately correct if these angles are small enough (that is, for rays close to the central axis). Substituting Eqs. 34-17 into Eq. 34-16, using Eq. 34-3 to replace \( r \) with \( 2f \), and canceling \( ac \) lead exactly to Eq. 34-4, the relation that we set out to prove.

The Refracting Surface Formula (Eq. 34-8)

The incident ray from point object \( O \) in Fig. 34-23 that falls on point \( a \) of a spherical refracting surface is refracted there according to Eq. 33-40,

\[
n_1 \sin \theta_1 = n_2 \sin \theta_2.
\]

If \( \alpha \) is small, \( \theta_1 \) and \( \theta_2 \) will also be small and we can replace the sines of these angles with the angles themselves. Thus, the equation above becomes

\[
n_1 \theta_1 = n_2 \theta_2. \tag{34-18}
\]

We again use the fact that an exterior angle of a triangle is equal to the sum of the two opposite interior angles. Applying this to triangles \( COa \) and \( ICa \) yields

\[
\theta_1 = \alpha + \beta \quad \text{and} \quad \beta = \theta_1 + \gamma. \tag{34-19}
\]

If we use Eqs. 34-19 to eliminate \( \theta_1 \) and \( \theta_2 \) from Eq. 34-18, we find

\[
n_1 \alpha + n_2 \gamma = (n_2 - n_1)\beta. \tag{34-20}
\]

In radian measure the angles \( \alpha, \beta, \) and \( \gamma \) are

\[
\alpha = \frac{ac}{p}; \quad \beta = \frac{ac}{r}; \quad \gamma = \frac{ac}{i}. \tag{34-21}
\]

Only the second of these equations is exact. The other two are approximate because \( I \) and \( O \) are not the centers of circles of which \( ac \) is a part. However, for \( \alpha \) small enough (for rays close to the axis), the inaccuracies in Eqs. 34-21 are small. Substituting Eqs. 34-21 into Eq. 34-20 leads directly to Eq. 34-8, as we wanted.

The Thin-Lens Formulas (Eqs. 34-9 and 34-10)

Our plan is to consider each lens surface as a separate refracting surface, and to use the image formed by the first surface as the object for the second.

We start with the thick glass “lens” of length \( L \) in Fig. 34-24 whose left and right refracting surfaces are ground to radii \( r' \) and \( r'' \). A point object \( O' \) is placed near the left surface as shown. A ray leaving \( O' \) along the central axis is not deflected on entering or leaving the lens.

A second ray leaving \( O' \) at an angle \( \alpha \) with the central axis intersects the left surface at point \( a' \), is refracted, and intersects the second (right) surface at point \( a'' \).
Figure 34-24 (a) Two rays from point object \( O' \) form a real image \( I'' \) after refracting through two spherical surfaces of a lens. The object faces a convex surface at the left side of the lens and a concave surface at the right side. The ray traveling through points \( a' \) and \( a'' \) is actually close to the central axis through the lens. (b) The left side and (c) the right side of the lens in (a), shown separately.

The ray is again refracted and crosses the axis at \( I'' \), which, being the intersection of two rays from \( O' \), is the image of point \( O' \), formed after refraction at two surfaces.

Figure 34-24b shows that the first (left) surface also forms a virtual image of \( O' \) at \( I' \). To locate \( I' \), we use Eq. 34-8,

\[
\frac{n_1}{p} + \frac{n_2}{i} = \frac{n_2 - n_1}{r}.
\]

Putting \( n_1 = 1 \) for air and \( n_2 = n \) for lens glass and bearing in mind that the (virtual) image distance is negative (that is, \( i = -i' \) in Fig. 34-24b), we obtain

\[
\frac{1}{p'} - \frac{n}{i'} = \frac{n - 1}{r'}.
\]  \hspace{1cm} (34-22)

(Because the minus sign is explicit, \( i' \) will be a positive number.)

Figure 34-24c shows the second surface again. Unless an observer at point \( a'' \) were aware of the existence of the first surface, the observer would think that the light striking that point originated at point \( I' \) in Fig. 34-24b and that the region to the left of the surface was filled with glass as indicated. Thus, the (virtual) image \( I' \) formed by the first surface serves as a real object \( O'' \) for the second surface. The distance of this object from the second surface is

\[
p'' = i' + L. \hspace{1cm} (34-23)
\]

To apply Eq. 34-8 to the second surface, we must insert \( n_1 = n \) and \( n_2 = 1 \) because the object now is effectively imbedded in glass. If we substitute with Eq. 34-23, then Eq. 34-8 becomes

\[
\frac{n}{i'' + L} + \frac{1}{i'} = \frac{1 - n}{r''}. \hspace{1cm} (34-24)
\]

Let us now assume that the thickness \( L \) of the “lens” in Fig. 34-24a is so small that we can neglect it in comparison with our other linear quantities (such as \( p' \), \( i' \), \( p'' \), \( i'' \), \( r' \), and \( r'' \)). In all that follows we make this \textit{thin-lens approximation}. Putting \( L = 0 \) in Eq. 34-24 and rearranging the right side lead to

\[
\frac{n}{i'} + \frac{1}{i''} = -\frac{n - 1}{r''}. \hspace{1cm} (34-25)
\]
Adding Eqs. 34-22 and 34-25 leads to
\[
\frac{1}{p'} + \frac{1}{i} = (n - 1) \left( \frac{1}{r'} - \frac{1}{r''} \right).
\]

Finally, calling the original object distance simply \( p \) and the final image distance simply \( i \) leads to
\[
\frac{1}{p} + \frac{1}{i} = (n - 1) \left( \frac{1}{r'} - \frac{1}{r''} \right),
\]
which, with a small change in notation, is Eqs. 34-9 and 34-10.

**Review & Summary**

**Real and Virtual Images** An image is a reproduction of an object via light. If the image can form on a surface, it is a real image and can exist even if no observer is present. If the image requires the visual system of an observer, it is a virtual image.

**Image Formation** Spherical mirrors, spherical refracting surfaces, and thin lenses can form images of a source of light—the object—by redirecting rays emerging from the source. The image occurs where the redirected rays cross (forming a real image) or where backward extensions of those rays cross (forming a virtual image). If the rays are sufficiently close to the central axis through the spherical mirror, refracting surface, or thin lens, we have the following relations between the object distance \( p \) (which is positive) and the image distance \( i \) (which is positive for real images and negative for virtual images):

1. **Spherical Mirror**:
   \[
   \frac{1}{p} + \frac{1}{i} = \frac{1}{f} = \frac{2}{r},
   \]
   where \( f \) is the mirror's focal length and \( r \) is its radius of curvature. A plane mirror is a special case for which \( r \rightarrow \infty \), so that \( p = -i \). Real images form on the side of a mirror where the object is located, and virtual images form on the opposite side.

2. **Spherical Refracting Surface**:
   \[
   \frac{n_1}{p} + \frac{n_2}{i} = \frac{n_2 - n_1}{r} \quad \text{(single surface)},
   \]
   where \( n_1 \) is the index of refraction of the material where the object is located, \( n_2 \) is the index of refraction of the material on the other side of the refracting surface, and \( r \) is the radius of curvature of the surface. When the object faces a convex refracting surface, the radius \( r \) is positive. When it faces a concave surface, \( r \) is negative. Real images form on the side of a refracting surface that is opposite the object, and virtual images form on the same side as the object.

3. **Thin Lens**:
   \[
   \frac{1}{p} + \frac{1}{i} = \frac{1}{f} = (n - 1) \left( \frac{1}{r_1} - \frac{1}{r_2} \right),
   \]
   where \( f \) is the lens's focal length, \( n \) is the index of refraction of the lens material, and \( r_1 \) and \( r_2 \) are the radii of curvature of the two sides of the lens, which are spherical surfaces. A convex lens surface that faces the object has a positive radius of curvature; a concave lens surface that faces the object has a negative radius of curvature. Real images form on the side of a lens that is opposite the object, and virtual images form on the same side as the object.

**Lateral Magnification** The lateral magnification \( m \) produced by a spherical mirror or a thin lens is
\[
m = -\frac{i}{p},
\]
The magnitude of \( m \) is given by
\[
|m| = \frac{h'}{h},
\]
where \( h \) and \( h' \) are the heights (measured perpendicular to the central axis) of the object and image, respectively.

**Optical Instruments** Three optical instruments that extend human vision are:

1. The **simple magnifying lens**, which produces an angular magnification \( m_\theta \) given by
   \[
   m_\theta = \frac{25 \text{ cm}}{f},
   \]
   where \( f \) is the focal length of the magnifying lens. The distance of 25 cm is a traditionally chosen value that is a bit more than the typical near point for someone 20 years old.

2. The **compound microscope**, which produces an overall magnification \( M \) given by
   \[
   M = mm_\theta = -\frac{s}{f_{ob}} \frac{25 \text{ cm}}{f_{ey}},
   \]
   where \( m \) is the lateral magnification produced by the objective, \( m_\theta \) is the angular magnification produced by the eyepiece, \( s \) is the tube length, and \( f_{ob} \) and \( f_{ey} \) are the focal lengths of the objective and eyepiece, respectively.

3. The **refracting telescope**, which produces an angular magnification \( m_\theta \) given by
   \[
   m_\theta = -\frac{f_{ob}}{f_{ey}}
   \]
1. Figure 34-25 shows a fish and a fish stalker in water. (a) Does the stalker see the fish in the general region of point $a$ or point $b$? (b) Does the stalker see the (wild) eyes of the stalker in the general region of point $c$ or point $d$?

2. In Fig. 34-26, stick figure $O$ stands in front of a spherical mirror that is mounted within the boxed region; the central axis through the mirror is shown. The four stick figures $I_1$ to $I_4$ suggest general locations and orientations for the images that might be produced by the mirror. (The figures are only sketched in; neither their heights nor their distances from the mirror are drawn to scale.) (a) Which of the stick figures could not possibly represent images? Of the possible images, (b) which would be due to a concave mirror, (c) which would be due to a convex mirror, (d) which would be virtual, and (e) which would involve negative magnification?

3. Figure 34-27 is an overhead view of a mirror maze based on floor sections that are equilateral triangles. Every wall within the maze is mirrored. If you stand at entrance $x$, (a) which of the maze monsters $a$, $b$, and $c$ is the stalker see the fish in the general region of point $a$ or point $b$? (b) how many times does each visible monster appear in a hallway; and (c) what is at the far end of a hallway?

4. A penguin waddles along the central axis of a concave mirror, from the focal point to an effectively infinite distance. (a) How does its image move? (b) Does the height of its image increase continuously, decrease continuously, or change in some more complicated manner?

5. When a T. rex pursues a jeep in the movie "Jurassic Park," we see a reflected image of the T. rex via a side-view mirror, on which is printed the (then darkly humorous) warning: "Objects in mirror are closer than they appear." Is the mirror flat, convex, or concave?

6. An object is placed against the center of a concave mirror and then moved along the central axis until it is 5.0 m from the mirror. During the motion, the distance $l$ between the mirror and the image it produces is measured. The procedure is then repeated with a convex mirror and a plane mirror. Figure 34-28 gives the results versus object distance $p$. Which curve corresponds to which mirror? (Curve 1 has two segments.)

7. The table details six variations of the basic arrangement of two thin lenses represented in Fig. 34-29. (The points labeled $F_1$ and $F_2$ are the focal points of lenses 1 and 2.) An object is distance $p_1$ to the left of lens 1, as in Fig. 34-18. (a) For which variations can we tell, without calculation, whether the final image (that due to lens 2) is to the left or right of lens 2 and whether it has the same orientation as the object? (b) For those “easy” variations, give the image location as “left” or “right” and the orientation as “same” or “inverted.”

8. An object is placed against the center of a converging lens and then moved along the central axis until it is 5.0 m from the lens. During the motion, the distance $l$ between the lens and the image it produces is measured. The procedure is then repeated with a diverging lens. Which of the curves in Fig. 34-28 best gives $l$ versus the object distance $p$ for these lenses? (Curve 1 consists of two segments. Curve 3 is straight.)

9. Figure 34-30 shows four thin lenses, all of the same material, with sides that either are flat or have a radius of curvature of magnitude 10 cm. Without written calculation, rank the lenses according to the magnitude of the focal length, greatest first.

10. In Fig. 34-26, stick figure $O$ stands in front of a thin, symmetric lens that is mounted within the boxed region; the central axis through the lens is shown. The four stick figures $I_1$ to $I_4$ suggest general locations and orientations for the images that might be produced by the lens. (The figures are only sketched in; neither their height nor their distance from the lens are drawn to scale.) (a) Which of the stick figures could not possibly represent images? Of the possible images, (b) which would be due to a converging lens, (c) which would be due to a diverging lens, (d) which would be virtual, and (e) which would involve negative magnification?

11. Figure 34-31 shows a coordinate system in front of a flat mirror, with the $x$ axis perpendicular to the mirror. Draw the image of the system in the mirror. (a) Which axis is reversed by the reflection? (b) If you face a mirror, is your image inverted (top for bottom)? (c) Is it reversed left and right (as commonly believed)? (d) What then is reversed?
Module 34-1  Images and Plane Mirrors

1 You look through a camera toward an image of a hummingbird in a plane mirror. The camera is 4.30 m in front of the mirror. The bird is at camera level, 5.00 m to your right and 3.30 m from the mirror. What is the distance between the camera and the apparent position of the bird’s image in the mirror?

2 ILW A moth at about eye level is 10 cm in front of a plane mirror; you are behind the moth, 30 cm from the mirror. What is the distance between your eyes and the apparent position of the moth’s image in the mirror?

3 In Fig. 34-32, an isotropic point source of light $S$ is positioned at distance $d$ from a viewing screen $A$ and the light intensity $I_p$ at point $P$ (level with $S$) is measured. Then a plane mirror $M$ is placed behind $S$ at distance $d$. By how much is $I_p$ multiplied by the presence of the mirror?

4 Figure 34-33 shows an overhead view of a corridor with a plane mirror $M$ mounted at one end. A burglar $B$ sneaks along the corridor directly toward the center of the mirror. If $d = 3.0$ m, how far from the mirror will she be when the security guard $S$ can first see her in the mirror?

5 SSM WWW Figure 34-34 shows a small light bulb suspended at distance $d_1 = 250$ cm above the surface of the water in a swimming pool where the water depth is $d_2 = 200$ cm. The bottom of the pool is a large mirror. How far below the mirror surface is the image of the bulb? (Hint: Assume that the rays are close to a vertical axis through the bulb, and use the small-angle approximation in which $\sin \theta = \tan \theta = \theta$.)

Module 34-2  Spherical Mirrors

6 An object is moved along the central axis of a spherical mirror while the lateral magnification $m$ of it is measured. Figure 34-35 gives $m$ versus object distance $p$ for the range $p_a = 2.0$ cm to $p_b = 8.0$ cm. What is $m$ for $p = 14.0$ cm?

7 A concave shaving mirror has a radius of curvature of 35.0 cm. It is positioned so that the (upright) image of a man’s face is 2.50 times the size of the face. How far is the mirror from the face?

8 An object is placed against the center of a spherical mirror and then moved 70 cm from it along the central axis as the image distance $i$ is measured. Figure 34-36 gives $i$ versus object distance $p$ out to $p_i = 40$ cm. What is $i$ for $p = 70$ cm?

9 through 16 SSM 9, 11, 13 Spherical mirrors. Object $O$ stands on the central axis of a spherical mirror. For this situation, each problem in Table 34-3 gives object distance $p_o$ (centimeters), the type of mirror, and then the distance (centimeters, without proper sign) between the focal point and the mirror. Find (a) the radius of curvature $r$, (b) the image distance $i$, and (c) the lateral magnification $m$. Also, determine whether the image is (d) real (R) or virtual (V), (e) inverted (I) from object $O$ or noninverted (NI), and (f) on the same side of the mirror as $O$ or on the opposite side.

17 through 29 SSM 23, 29 More mirrors. Object $O$ stands on the central axis of a spherical or plane mirror. For this sit-

Figure 34-37 gives the lateral magnification \( m \) of an object versus the object distance \( p \) from a spherical mirror as the object is moved along the mirror’s central axis through a range of values for \( p \). The horizontal scale is set by \( p_i = 10.0 \) cm. What is the magnification of the object when the object is 21 cm from the mirror?

**30** (a) A luminous point is moving at speed \( v_o \) toward a spherical mirror with radius of curvature \( r \), along the central axis of the mirror. Show that the image of this point is moving at speed

\[
v_l = \left( \frac{r}{2p - r} \right)^2 v_o,
\]

where \( p \) is the distance of the luminous point from the mirror at any given time. Now assume the mirror is concave, with \( r = 15 \) cm, and let \( v_o = 5.0 \) cm/s. Find \( v_l \) when (b) \( p = 30 \) cm (far outside the focal point), (c) \( p = 8.0 \) cm (just outside the focal point), and (d) \( p = 10 \) mm (very near the mirror).

**Module 34-3 Spherical Refracting Surfaces**

**32 through 38** 37, 38 SSM 33, 35 Spherical refracting surfaces. An object \( O \) stands on the central axis of a spherical refracting surface. For this situation, each problem in Table 34-5 refers to the index of refraction \( n_1 \) where the object is located, (a) the index of refraction \( n_2 \) on the other side of the refracting surface, (b) the object distance \( p \), (c) the radius of curvature \( r \) of the surface, and (d) the image distance \( i \). (All distances are in centimeters.) Fill in the missing information, including whether the image is (e) real (R) or virtual (V) and (f) on the same side of the surface as object \( O \) or on the opposite side.

**39** In Fig. 34-38, a beam of parallel light rays from a laser is incident on a solid transparent sphere of index of refraction \( n \). (a) If a point image is produced at the back of the sphere, what is the index of refraction of the sphere? (b) What index of refraction, if any, will produce a point image at the center of the sphere?

**40** A glass sphere has radius \( R = 5.0 \) cm and index of refraction 1.6. A paperweight is constructed by slicing through the sphere along a plane that is 2.0 cm

from the center of the sphere, leaving height \( h = 3.0 \text{ cm} \). The paperweight is placed on a table and viewed from directly above by an observer who is distance \( d = 8.0 \text{ cm} \) from the tabletop (Fig. 34-39). When viewed through the paperweight, how far away does the tabletop appear to be to the observer?

**Module 34-4 Thin Lenses**

**41** A lens is made of glass having an index of refraction of 1.5. One side of the lens is flat, and the other is convex with a radius of curvature of 20 cm. (a) Find the focal length of the lens. (b) If an object is placed 40 cm in front of the lens, where is the image?

**42** Figure 34-40 gives the lateral magnification \( m \) of an object versus the object distance \( p \) from a lens as the object is moved along the central axis of the lens through a range of values for \( p \) out to \( p_i = 20.0 \text{ cm} \). What is the magnification of the object when the object is 35 cm from the lens?

**43** A movie camera with a (single) lens of focal length 75 mm takes a picture of a person standing 27 m away. If the person is 180 cm tall, what is the height of the image on the film?

**44** An object is placed against the center of a thin lens and then moved away from it along the central axis as the image distance \( i \) is measured. Figure 34-41 gives \( i \) versus object distance \( p \) out to \( p_i = 60 \text{ cm} \). What is the image distance when \( p = 100 \text{ cm} \)?

**45** You produce an image of the Sun on a screen, using a thin lens whose focal length is 20.0 cm. What is the diameter of the image? (See Appendix C for needed data on the Sun.)

**46** An object is placed against the center of a thin lens and then moved 70 cm from it along the central axis as the image distance \( i \) is measured. Figure 34-42 gives \( i \) versus object distance \( p \) out to \( p_i = 40 \text{ cm} \). What is the image distance when \( p = 70 \text{ cm} \)?

**47** A double-convex lens is to be made of glass with an index of refraction of 1.5. One surface is to have twice the radius of curvature of the other and the focal length is to be 60 mm. What is the (a) smaller and (b) larger radius?

**48** An object is moved along the central axis of a thin lens while the lateral magnification \( m \) is measured. Figure 34-43 gives \( m \) versus object distance \( p \) out to \( p_i = 8.0 \text{ cm} \). What is the magnification of the object when the object is 14.0 cm from the lens?

**49** An illuminated slide is held 44 cm from a screen. How far from the slide must a lens of focal length 11 cm be placed (between the slide and the screen) to form an image of the slide’s picture on the screen?

**50** through **57** Thin lenses. Object \( O \) stands on the central axis of a thin symmetric lens. For this situation, each problem in Table 34-6 gives object distance \( p \) (centimeters), the type of lens (C stands for converging and D for diverging), and then the distance (centimeters, without proper sign) between a focal point and the lens. Find (a) the image distance \( i \) and (b) the lateral magnification \( m \) of the object, including signs. Also, determine whether the image is (c) real (R) or virtual (V), (d) inverted (I) from object \( O \) or noninverted (NI), and (e) on the same side of the lens as object \( O \) or on the opposite side.

**58** through **67** Lenses with given radii. Object \( O \) stands in front of a thin lens, on the central axis. For this

| Table 34-6 Problems 50 through 57: Thin Lenses. See the setup for these problems. |
|---|---|---|---|---|---|
| **p** | **Lens** | **(a)** | **(b)** | **(c)** | **(d)** | **(e)** |
| 50 | +16 | C, 4.0 |   |   |   |   |
| 51 | +12 | C, 16 |   |   |   |   |
| 52 | +25 | C, 35 |   |   |   |   |
| 53 | +8.0 | D, 12 |   |   |   |   |
| 54 | +10 | D, 6.0 |   |   |   |   |
| 55 | +22 | D, 14 |   |   |   |   |
| 56 | +12 | D, 31 |   |   |   |   |
| 57 | +45 | C, 20 |   |   |   |   |
situation, each problem in Table 34-7 gives object distance \( p \), index of refraction \( n \) of the lens, radius \( r_1 \) of the nearer lens surface, and radius \( r_2 \) of the farther lens surface. (All distances are in centimeters.) Find (a) the image distance \( i \) and (b) the lateral magnification \( m \) of the object, including signs. Also, determine whether the image is (c) real (R) or virtual (V), (d) inverted (I) from object \( O \) or noninverted (NI), and (e) on the same side of the lens as object \( O \) or on the opposite side.

In Fig. 34-44, a real inverted image \( I \) of an object \( O \) is formed by a particular lens (not shown); the object–image separation is \( d = 40.0 \) cm, measured along the central axis of the lens. The image is just half the size of the object. (a) What kind of lens must be used to produce this image? (b) How far from the object must the lens be placed? (c) What is the focal length of the lens?

**69 through 79** More lenses. Object \( O \) stands on the central axis of a thin symmetric lens. For this situation, each problem in Table 34-8 refers to (a) the lens type, converging (C) or diverging (D), (b) the focal distance \( f \), (c) the object distance \( p \), (d) the image distance \( i \), and (e) the lateral magnification \( m \). (All distances are in centimeters.) It also refers to whether (f) the image is real (R) or virtual (V), (g) inverted (I) or noninverted (NI) from \( O \), and (h) on the same side of the lens as \( O \) or on the opposite side. Fill in the missing information, including the value of \( m \) when only an inequality is given. Where only a sign is missing, answer with the sign.

**80 through 87** Two-lens systems. In Fig. 34-45, stick figure \( O \) (the object) stands on the common central axis of two thin, symmetric lenses, which are mounted in the boxed regions. Lens 1 is mounted within the boxed region closer to \( O \), which is at object distance \( p_1 \). Lens 2 is mounted within the farther

boxed region, at distance \( d \). Each problem in Table 34-9 refers to a different combination of lenses and different values for distances, which are given in centimeters. The type of lens is indicated by C for converging and D for diverging; the number after C or D is the distance between a lens and either of its focal points (the proper sign of the focal distance is not indicated).

Find (a) the image distance \( i_2 \) for the image produced by lens 2 (the final image produced by the system) and (b) the overall lateral magnification \( M \) for the system, including signs. Also, determine whether the final image is (c) real (R) or virtual (V), (d) inverted (I) from object \( O \) or noninverted (NI), and (e) on the same side of lens 2 as object \( O \) or on the opposite side.

Module 34-5  Optical Instruments

**88** If the angular magnification of an astronomical telescope is 36 and the diameter of the eyepiece required to collect all the light entering the objective from a distant point source on the telescope axis?

**89 SSM** In a microscope of the type shown in Fig. 34-20, the focal length of the objective is 4.00 cm, and that of the eyepiece is 8.00 cm. The distance between the lenses is 25.0 cm. (a) What is the tube length \( s \)? (b) If image \( I \) in Fig. 34-20 is to be just inside focal point \( F_1 \), how far from the objective should the object be? What then are (c) the lateral magnification \( m \) of the objective, (d) the angular magnification \( m_s \) of the eyepiece, and (e) the overall magnification \( M \) of the microscope?

**90** Figure 34-46a shows the basic structure of an old film camera. A lens can be moved forward or back to produce an image on film at the back of the camera. For a certain camera, with the distance \( i \) between the lens and the film set at \( f = 5.0 \text{ cm} \), parallel light rays from a very distant object \( O \) converge to a point image on the film, as shown. The object is now brought closer, to a distance of \( p = 100 \text{ cm} \), and the lens–film distance is adjusted so that an inverted real image forms on the film (Fig. 34-46b). (a) What is the lens–film distance \( i \) now? (b) By how much was distance \( i \) changed?

**91 SSM** Figure 34-47a shows the basic structure of a human eye. Light refracts into the eye through the cornea and is then further redirected by a lens whose shape (and thus ability to focus the light) is controlled by muscles. We can treat the cornea and eye lens as a single effective thin lens (Fig. 34-47b). A “normal” eye can focus parallel light rays from a distant object \( O \) to a point on the retina at the back of the eye, where processing of the visual information begins. As an object is brought close to the eye, however, the muscles must change the shape of the lens so that rays form an inverted real image on the retina (Fig. 34-47c). (a) Suppose that for the parallel rays of Figs. 34-47a and \( b \), the focal length \( f \) of the effective thin lens of the eye is 2.50 cm. For an object at distance \( p = 40.0 \text{ cm} \), what focal length \( f' \) of the effective lens is required for the object to be seen clearly? (b) Must the eye muscles increase or decrease the radii of curvature of the eye lens to give focal length \( f' \)?

**92** An object is 10.0 mm from the objective of a certain compound microscope. The lenses are 300 mm apart, and the intermediate image is 50.0 mm from the eyepiece. What overall magnification is produced by the instrument?

**93** Someone with a near point \( P_n \) of 25 cm views a thimble through a simple magnifying lens of focal length 10 cm by placing
the lens near his eye. What is the angular magnification of the thimble if it is positioned so that its image appears at (a) \( P_a \) and (b) infinity?

**Additional Problems**

94 An object is placed against the center of a spherical mirror and then moved 70 cm from it along the central axis as the image distance \( i \) is measured. Figure 34-48 gives \( i \) versus object distance \( p \) out to \( p_1 = 40 \) cm. What is the image distance when the object is 70 cm from the mirror?

95 through 100 [95, 96, 99] **Three-lens systems.** In Fig. 34-49, stick figure \( O \) (the object) stands on the common central axis of three thin, symmetric lenses, which are mounted in the boxed regions. Lens 1 is mounted within the boxed region closest to \( O \), which is at object distance \( p_1 \). Lens 2 is mounted within the middle boxed region, at distance \( d_{12} \) from lens 1. Lens 3 is mounted in the farthest boxed region, at distance \( d_{23} \) from lens 2. Each problem in Table 34-10 refers to a different combination of lenses and different values for distances, which are given in centimeters. The type of lens is indicated by \( C \) for converging and \( D \) for diverging; the number after \( C \) or \( D \) is the distance between a lens and either of the focal points (the proper sign of the focal distance is not indicated).

Find (a) the image distance \( i_3 \) for the (final) image produced by lens 3 (the final image produced by the system) and (b) the overall lateral magnification \( M \) for the system, including signs. Also, determine whether the final image is (c) real (R) or virtual (V), (d) inverted (I) from object \( O \) or noninverted (NI), and (e) on the same side of lens 3 as object \( O \) or on the opposite side.

101 SSM The formula \( 1/p + 1/i = 1/f \) is called the Gaussian form of the thin-lens formula. Another form of this formula, the Newtonian form, is obtained by considering the distance \( x \) from the object to the first focal point and the distance \( x' \) from the second focal point to the image. Show that \( xx' = f^2 \) is the Newtonian form of the thin-lens formula.

102 Figure 34-50a is an overhead view of two vertical plane mirrors with an object \( O \) placed between them. If you look into the mirrors, you see multiple images of \( O \). You can find them by drawing the reflection in each mirror of the angular region between the mirrors, as is done in Fig. 34-50b for the left-hand mirror. Then draw the reflection of the reflection. Continue this on the left and on the right until the reflections meet or overlap at the rear of the mirrors. Then you can count the number of images of \( O \). How many images of \( O \) would you see if \( \theta \) is (a) 90°, (b) 45°, and (c) 60°? If \( \theta = 120° \), determine the (d) smallest and (e) largest number of images that can be seen, depending on your perspective and the location of \( O \). (f) In each situation, draw the image locations and orientations as in Fig. 34-50b.

103 SSM Two thin lenses of focal lengths \( f_1 \) and \( f_2 \) are in contact and share the same central axis. Show that, in image formation, they are equivalent to a single thin lens for which the focal length is \( f = f_1 f_2/(f_1 + f_2) \).

104 Two plane mirrors are placed parallel to each other and 40 cm apart. An object is placed 10 cm from one mirror. Determine the (a) smallest, (b) second smallest, (c) third smallest (occurs twice), and (d) fourth smallest distance between the object and image of the object.

105 In Fig. 34-51, a box is somewhere at the left, on the central axis of the thin converging lens. The image \( I_m \) of the box produced by the plane mirror is 4.00 cm “inside” the mirror. The lens–mirror separation is 10.0 cm, and the focal length of the lens is 2.00 cm. (a) What is the distance between the box and the lens? Light reflected by the mirror travels back through the lens, which produces a final image of the box. (b) What is the distance between the lens and that final image?

106 In Fig. 34-52, an object is placed in front of a converging lens at a distance equal to twice the focal length $f_1$ of the lens. On the other side of the lens is a concave mirror of focal length $f_2$ separated from the lens by a distance $2(f_1 + f_2)$. Light from the object passes rightward through the lens, reflects from the mirror, passes leftward through the lens, and forms a final image of the object. What are (a) the distance between the lens and that final image and (b) the overall lateral magnification $M$ of the object? Is the image (c) real or virtual (if it is virtual, it requires someone looking through the lens toward the mirror), (d) to the left or right of the lens, and (e) inverted or noninverted relative to the object?

107 SSM A fruit fly of height $H$ sits in front of lens 1 on the central axis through the lens. The lens forms an image of the fly at a distance $d = 20$ cm from the fly; the image has the fly’s orientation and height $H_I = 2.0H$. What are (a) the focal length $f_1$ of the lens and (b) the object distance $p_1$ of the fly? The fly then leaves lens 1 and sits in front of lens 2, which also forms an image at $d = 20$ cm that has the same orientation as the fly, but now $H_I = 0.50H$. What are (c) $f_2$ and (d) $p_2$?

108 You grind the lenses shown in Fig. 34-53 from flat glass disks ($n = 1.5$) using a machine that can grind a radius of curvature of either 40 cm or 60 cm. In a lens where either radius is appropriate, you select the 40 cm radius. Then you hold each lens in sunshine to form an image of the Sun. What are the (a) focal length $f$ and (b) image type (real or virtual) for (bi-convex) lens 1, (c) $f$ and (d) image type for (plane-convex) lens 2, (e) $f$ and (f) image type for (meniscus concave) lens 3, (g) $f$ and (h) image type for (bi-concave) lens 4, (i) $f$ and (j) image type for (plane-concave) lens 5, and (k) $f$ and (l) image type for (meniscus concave) lens 6?

109 In Fig. 34-54, a fish watcher at point $P$ watches a fish through a glass wall of a fish tank. The watcher is level with the fish; the index of refraction of the glass is $8/5$, and that of the water is $4/3$. The distances are $d_1 = 8.0$ cm, $d_2 = 3.0$ cm, and $d_3 = 6.8$ cm. (a) To the fish, how far away does the watcher appear to be? (Hint: The watcher is the object. Light from that object passes through the wall’s outside surface, which acts as a refracting surface. Find the image produced by that surface. Then treat that image as an object whose light passes through the wall’s inside surface, which acts as another refracting surface.) (b) To the watcher, how far away does the fish appear to be?

110 A goldfish in a spherical fish bowl of radius $R$ is at the level of the center $C$ of the bowl and at distance $R/2$ from the glass (Fig. 34-55). What magnification of the fish is produced by the water in the bowl for a viewer looking along a line that includes the fish and the center, with the fish on the near side of the center? The index of refraction of the water is 1.33. Neglect the glass wall of the bowl. Assume the viewer looks with one eye. (Hint: Equation 34-5 holds, but Eq. 34-6 does not. You need to work with a ray diagram of the situation and assume that the rays are close to the observer’s line of sight—that is, they deviate from that line by only small angles.)

111 Figure 34-56 shows a beam expander made with two coaxial converging lenses of focal lengths $f_1$ and $f_2$ and separation $d = f_1 + f_2$. The device can expand a laser beam while keeping the light rays in the beam parallel to the central axis through the lenses. Suppose a uniform laser beam of width $W_i = 2.5$ mm and intensity $I_i = 9.0$ kW/m$^2$ enters a beam expander for which $f_1 = 12.5$ cm and $f_2 = 30.0$ cm. What are (a) $W_i$ and (b) $I_i$ of the beam leaving the expander? (c) What value of $d$ is needed for the beam expander if lens 1 is replaced with a diverging lens of focal length $f_1 = -26.0$ cm?

112 You look down at a coin that lies at the bottom of a pool of liquid of depth $d$ and index of refraction $n$ (Fig. 34-57). Because you view with two eyes, which intercept different rays of light from the coin, you perceive the coin to be where extensions of the intercepted rays cross, at depth $d_i$ instead of $d$. Assuming that the intercepted rays in Fig. 34-57 are close to a vertical axis through the coin, show that $d_i = d/n$. (Hint: Use the small-angle approximation $\sin \theta = \tan \theta = \theta$.)

113 A pinhole camera has the hole a distance $12$ cm from the film plane, which is a rectangle of height $8.0$ cm and width $6.0$ cm. How far from a painting of dimensions $50$ cm by $50$ cm should the camera be placed so as to get the largest complete image possible on the film plane?

114 Light travels from point $A$ to point $B$ via reflection at point $O$ on the surface of a mirror. Without using calculus, show that length $AOB$ is a minimum when the angle of incidence $\theta$ is equal to the angle of reflection $\phi$. (Hint: Consider the image of $A$ in the mirror.)
A point object is 10 cm away from a plane mirror, and the eye of an observer (with pupil diameter 5.0 mm) is 20 cm away. Assuming the eye and the object to be on the same line perpendicular to the mirror surface, find the area of the mirror used in observing the reflection of the point. (Hint: Adapt Fig. 34-4.)

Show that the distance between an object and its real image formed by a thin converging lens is always greater than or equal to four times the focal length of the lens.

A luminous object and a screen are a fixed distance \( D \) apart. (a) Show that a converging lens of focal length \( f \), placed between object and screen, will form a real image on the screen for two lens positions that are separated by a distance \( d = \sqrt{D(D - 4f)} \). (b) Show that

\[
\left( \frac{D - d}{D + d} \right)^2
\]

gives the ratio of the two image sizes for these two positions of the lens.

An eraser of height 1.0 cm is placed 10.0 cm in front of a two-lens system. Lens 1 (nearer the eraser) has focal length \( f_1 = -15 \) cm, lens 2 has \( f_2 = 12 \) cm, and the lens separation is \( d = 12 \) cm. For the image produced by lens 2, what are (a) the image distance \( i_2 \) (including sign), (b) the image height, (c) the image type (real or virtual), and (d) the image orientation (inverted relative to the eraser or not inverted)?

A peanut is placed 40 cm in front of a two-lens system: lens 1 (nearer the peanut) has focal length \( f_1 = +20 \) cm, lens 2 has \( f_2 = -15 \) cm, and the lens separation is \( d = 10 \) cm. For the image produced by lens 2, what are (a) the image distance \( i_2 \) (including sign), (b) the image orientation (inverted relative to the peanut or not inverted), and (c) the image type (real or virtual)? (d) What is the net lateral magnification?

A coin is placed 20 cm in front of a two-lens system. Lens 1 (nearer the coin) has focal length \( f_1 = +10 \) cm, lens 2 has \( f_2 = +12.5 \) cm, and the lens separation is \( d = 30 \) cm. For the image produced by lens 2, what are (a) the image distance \( i_2 \) (including sign), (b) the overall lateral magnification, (c) the image type (real or virtual), and (d) the image orientation (inverted relative to the coin or not inverted)?

An object is 20 cm to the left of a thin diverging lens that has a 30 cm focal length. (a) What is the image distance \( i_1 \)? (b) Draw a ray diagram showing the image position.

In Fig 34-58 a pinecone is at distance \( p_1 = 1.0 \) m in front of a lens of focal length \( f_1 = 0.50 \) m; a flat mirror is at distance \( d = 2.0 \) m behind the lens. Light from the pinecone passes rightward through the lens, reflects from the mirror, passes leftward through the lens, and forms a final image of the pinecone. What are (a) the distance between the lens and that image and (b) the overall lateral magnification of the pinecone? Is the image (c) real or virtual (if it is virtual, it requires someone looking through the lens toward the mirror), (d) to the left or right of the lens, and (e) inverted relative to the pinecone or not inverted?

One end of a long glass rod \( (n = 1.5) \) is a convex surface of radius 6.0 cm. An object is located in air along the axis of the rod, at a distance of 10 cm from the convex end. (a) How far apart are the object and the image formed by the glass rod? (b) Within what range of distances from the end of the rod must the object be located in order to produce a virtual image?

A short straight object of length \( L \) lies along the central axis of a spherical mirror, a distance \( p \) from the mirror. (a) Show that its image in the mirror has a length \( L' \), where

\[
L' = L \left( \frac{f}{p - f} \right)^2.
\]

(Hint: Locate the two ends of the object.) (b) Show that the longitudinal magnification \( m' (= L'/L) \) is equal to \( m^2 \), where \( m \) is the lateral magnification.

Prove that if a plane mirror is rotated through an angle \( \alpha \), the reflected beam is rotated through an angle \( 2\alpha \). Show that this result is reasonable for \( \alpha = 45^\circ \).

An object is 30.0 cm from a spherical mirror, along the mirror’s central axis. The mirror produces an inverted image with a lateral magnification of absolute value 0.500. What is the focal length of the mirror?

A concave mirror has a radius of curvature of 24 cm. How far from an object the image formed is (a) virtual and 3.0 times the size of the object, (b) real and 3.0 times the size of the object, and (c) real and 1/3 the size of the object?

A pepper seed is placed in front of a lens. The lateral magnification of the seed is +0.300. The absolute value of the lens’s focal length is 40.0 cm. How far from the lens is the image?

The equation \( 1/p + 1/i = 2/r \) for spherical mirrors is an approximation that is valid if the image is formed by rays that make only small angles with the central axis. In reality, many of the angles are large, which smears the image a little. You can determine how much. Refer to Fig. 34-22 and consider a ray that leaves a point source (the object) on the central axis and that makes an angle \( \alpha \) with that axis.

First, find the point of intersection of the ray with the mirror. If the coordinates of this intersection point are \( x \) and \( y \) and the origin is placed at the center of curvature, then \( y = (x + p - r) \tan \alpha \) and \( x^2 + y^2 = r^2 \), where \( p \) is the object distance and \( r \) is the mirror’s radius of curvature. Next, use \( \tan \beta = y/x \) to find the angle \( \beta \) at the point of intersection, and then use \( \alpha + \gamma = 2\beta \) to find the value of \( \gamma \). Finally, use the relation \( \tan \gamma = y/(x + i - r) \) to find the distance \( i \) of the image.

(a) Suppose \( r = 12 \) cm and \( p = 20 \) cm. For each of the following values of \( \alpha \), find the position of the image — that is, the position of the point where the reflected ray crosses the central axis: 0.500, 0.100, 0.0100 rad. Compare the results with those obtained with the equation \( 1/p + 1/i = 2/r \). (b) Repeat the calculations for \( p = 4.00 \) cm.

A small cup of green tea is positioned on the central axis of a spherical mirror. The lateral magnification of the cup is +0.250, and the distance between the mirror and its focal point is 2.00 cm. (a) What is the distance between the mirror and the image it produces? (b) Is the focal length positive or negative? (c) Is the image real or virtual?

A 20-mm-thick layer of water \( (n = 1.33) \) floats on a 40-mm-thick layer of carbon tetrachloride \( (n = 1.46) \) in a tank. A coin lies at the bottom of the tank. At what depth below the top water surface do you perceive the coin? (Hint: Use the result and assumptions of Problem 112 and work with a ray diagram.)
132 A millipede sits 1.0 m in front of the nearest part of the surface of a shiny sphere of diameter 0.70 m. (a) How far from the surface does the millipede’s image appear? (b) If the millipede’s height is 2.0 mm, what is the image height? (c) Is the image inverted?

133 (a) Show that if the object $O$ in Fig. 34-19c is moved from focal point $F_1$ toward the observer’s eye, the image moves in from infinity and the angle $\theta$ (and thus the angular magnification $m_\theta$) increases. (b) If you continue this process, where is the image when $m_\theta$ has its maximum usable value? (You can then still increase $m_\theta$, but the image will no longer be clear.) (c) Show that the maximum usable value of $m_\theta$ is $1 + (25 \text{ cm})/f$. (d) Show that in this situation the angular magnification is equal to the lateral magnification.

134 Isaac Newton, having convinced himself (erroneously as it turned out) that chromatic aberration is an inherent property of refracting telescopes, invented the reflecting telescope, shown schematically in Fig. 34-59. He presented his second model of this telescope, with a magnifying power of 38, to the Royal Society (of London), which still has it. In Fig. 34-59 incident light falls, closely parallel to the telescope axis, on the objective mirror $M$. After reflection from small mirror $M'$ (the figure is not to scale), the rays form a real, inverted image in the focal plane (the plane perpendicular to the line of sight, at focal point $F$). This image is then viewed through an eyepiece. (a) Show that the angular magnification $m_\theta$ for the device is given by Eq. 34-15:

$$m_\theta = -f_{ob}/f_{ey},$$

where $f_{ob}$ is the focal length of the objective mirror and $f_{ey}$ is that of the eyepiece. (b) The 200 in. mirror in the reflecting telescope at Mt. Palomar in California has a focal length of 16.8 m. Estimate the size of the image formed by this mirror when the object is a meter stick 2.0 km away. Assume parallel incident rays. (c) The mirror of a different reflecting astronomical telescope has an effective radius of curvature of 10 m ("effective" because such mirrors are ground to a parabolic rather than a spherical shape, to eliminate spherical aberration defects). To give an angular magnification of 200, what must be the focal length of the eyepiece?

135 A narrow beam of parallel light rays is incident on a glass sphere from the left, directed toward the center of the sphere. (The sphere is a lens but certainly not a thin lens.) Approximate the angle of incidence of the rays as 0°, and assume that the index of refraction of the glass is $n < 2.0$. (a) In terms of $n$ and the sphere radius $r$, what is the distance between the image produced by the sphere and the right side of the sphere? (b) Is the image to the left or right of that side? (Hint: Apply Eq. 34-8 to locate the image that is produced by refraction at the left side of the sphere; then use that image as the object for refraction at the right side of the sphere to locate the final image. In the second refraction, is the object distance $p$ positive or negative?)

136 A corner reflector, much used in optical, microwave, and other applications, consists of three plane mirrors fastened together to form the corner of a cube. Show that after three reflections, an incident ray is returned with its direction exactly reversed.

137 A cheese enchilada is 4.00 cm in front of a converging lens. The magnification of the enchilada is $-2.00$. What is the focal length of the lens?

138 A grasshopper hops to a point on the central axis of a spherical mirror. The absolute magnitude of the mirror’s focal length is 40.0 cm, and the lateral magnification of the image produced by the mirror is $+0.200$. (a) Is the mirror convex or concave? (b) How far from the mirror is the grasshopper?

139 In Fig. 34-60, a sand grain is 3.00 cm from thin lens 1, on the central axis through the two symmetric lenses. The distance between focal point and lens is 4.00 cm for both lenses; the lenses are separated by 8.00 cm. (a) What is the distance between lens 2 and the image it produces of the sand grain? Is that image (b) to the left or right of lens 2, (c) real or virtual, and (d) inverted relative to the sand grain or not inverted?

140 Suppose the farthest distance a person can see without visual aid is 50 cm. (a) What is the focal length of the corrective lens that will allow the person to see very far away? (b) Is the lens converging or diverging? (c) The power $P$ of a lens (in diopters) is equal to $1/f$, where $f$ is in meters. What is $P$ for the lens?

141 A simple magnifier of focal length $f$ is placed near the eye of someone whose near point $P_n$ is 25 cm. An object is positioned so that its image in the magnifier appears at $P_n$. (a) What is the angular magnification of the magnifier? (b) What is the angular magnification if the object is moved so that its image appears at infinity? For $f = 10$ cm, evaluate the angular magnifications of (c) the situation in (a) and (d) the situation in (b). (Viewing an image at $P_n$ requires effort by muscles in the eye, whereas viewing an image at infinity requires no such effort for many people.)
One of the major goals of physics is to understand the nature of light. This goal has been difficult to achieve (and has not yet fully been achieved) because light is complicated. However, this complication means that light offers many opportunities for applications, and some of the richest opportunities involve the interference of light waves — optical interference.

Nature has long used optical interference for coloring. For example, the wings of a Morpho butterfly are a dull, uninspiring brown, as can be seen on the 35-1 LIGHT AS A WAVE

Learning Objectives

After reading this module, you should be able to . . .

35.01 Using a sketch, explain Huygens’ principle.
35.02 With a few simple sketches, explain refraction in terms of the gradual change in the speed of a wavefront as it passes through an interface at an angle to the normal.
35.03 Apply the relationship between the speed of light in vacuum $c$, the speed of light in a material $v$, and the index of refraction of the material $n$.
35.04 Apply the relationship between a distance $L$ in a material, the speed of light in that material, and the time required for a pulse of the light to travel through $L$.
35.05 Apply Snell’s law of refraction.
35.06 When light refracts through an interface, identify that the frequency does not change but the wavelength and effective speed do.
35.07 Apply the relationship between the wavelength in vacuum $\lambda$, the wavelength $\lambda_n$ in a material (the internal wavelength), and the index of refraction $n$ of the material.

35.08 For light in a certain length of a material, calculate the number of internal wavelengths that fit into the length.
35.09 If two light waves travel through different materials with different indexes of refraction and then reach a common point, determine their phase difference and interpret the resulting interference in terms of maximum brightness, intermediate brightness, and darkness.
35.10 Apply the learning objectives of Module 17-3 (sound waves there, light waves here) to find the phase difference and interference of two waves that reach a common point after traveling paths of different lengths.
35.11 Given the initial phase difference between two waves with the same wavelength, determine their phase difference after they travel through different path lengths and through different indexes of refraction.
35.12 Identify that rainbows are examples of optical interference.

Key Ideas

● The three-dimensional transmission of waves, including light, may often be predicted by Huygens’ principle, which states that all points on a wavefront serve as point sources of spherical secondary wavelets. After a time $t$, the new position of the wavefront will be that of a surface tangent to these secondary wavelets.

● The law of refraction can be derived from Huygens’ principle by assuming that the index of refraction of any medium is $n = c/v$, in which $v$ is the speed of light in the medium and $c$ is the speed of light in vacuum.

● The wavelength $\lambda_n$ of light in a medium depends on the index of refraction $n$ of the medium:

$$\lambda_n = \frac{\lambda}{n},$$

in which $\lambda$ is the wavelength in vacuum.

● Because of this dependency, the phase difference between two waves can change if they pass through different materials with different indexes of refraction.

What Is Physics?

One of the major goals of physics is to understand the nature of light. This goal has been difficult to achieve (and has not yet fully been achieved) because light is complicated. However, this complication means that light offers many opportunities for applications, and some of the richest opportunities involve the interference of light waves — optical interference.

Nature has long used optical interference for coloring. For example, the wings of a Morpho butterfly are a dull, uninspiring brown, as can be seen on the
bottom wing surface, but the brown is hidden on the top surface by an arresting blue due to the interference of light reflecting from that surface (Fig. 35-1). Moreover, the top surface is color-shifting; if you change your perspective or if the wing moves, the tint of the color changes. Similar color shifting is used in the inks on many currencies to thwart counterfeitors, whose copy machines can duplicate color from only one perspective and therefore cannot duplicate any shift in color caused by a change in perspective.

To understand the basic physics of optical interference, we must largely abandon the simplicity of geometrical optics (in which we describe light as rays) and return to the wave nature of light.

**Light as a Wave**

The first convincing wave theory for light was in 1678 by Dutch physicist Christian Huygens. Mathematically simpler than the electromagnetic theory of Maxwell, it nicely explained reflection and refraction in terms of waves and gave physical meaning to the index of refraction.

Huygens’ wave theory is based on a geometrical construction that allows us to tell where a given wavefront will be at any time in the future if we know its present position. **Huygens’ principle** is:

All points on a wavefront serve as point sources of spherical secondary wavelets. After a time \( t \), the new position of the wavefront will be that of a surface tangent to these secondary wavelets.

Here is a simple example. At the left in Fig. 35-2, the present location of a wavefront of a plane wave traveling to the right in vacuum is represented by plane \( ab \), perpendicular to the page. Where will the wavefront be at time \( \Delta t \) later? We let several points on plane \( ab \) (the dots) serve as sources of spherical secondary wavelets that are emitted at \( t = 0 \). At time \( \Delta t \), the radius of all these spherical wavelets will have grown to \( c \Delta t \), where \( c \) is the speed of light in vacuum. We draw plane \( de \) tangent to these wavelets at time \( \Delta t \). This plane represents the wavefront of the plane wave at time \( \Delta t \); it is parallel to plane \( ab \) and a perpendicular distance \( c \Delta t \) from it.

**The Law of Refraction**

We now use Huygens’ principle to derive the law of refraction, Eq. 33-40 (Snell’s law). Figure 35-3 shows three stages in the refraction of several wavefronts at a flat interface between air (medium 1) and glass (medium 2). We arbitrarily choose the wavefronts in the incident light beam to be separated by \( \lambda_1 \), the wavelength in medium 1. Let the speed of light in air be \( v_1 \) and that in glass be \( v_2 \). We assume that \( v_2 < v_1 \), which happens to be true.
Angle $\theta_1$ in Fig. 35-3a is the angle between the wavefront and the interface; it has the same value as the angle between the normal to the wavefront (that is, the incident ray) and the normal to the interface. Thus, $\theta_1$ is the angle of incidence.

As the wave moves into the glass, a Huygens wavelet at point $e$ in Fig. 35-3b will expand to pass through point $c$, at a distance of $l_1$ from point $e$. The time interval required for this expansion is that distance divided by the speed of the wavelet, or $l_1/v_1$. Now note that in this same time interval, a Huygens wavelet at point $h$ will expand to pass through point $g$, at the reduced speed $v_2$ and with wavelength $\lambda_2$. Thus, this time interval must also be equal to $l_2/v_2$. By equating these times of travel, we obtain the relation

$$\frac{\lambda_1}{\lambda_2} = \frac{v_1}{v_2}, \quad (35-1)$$

which shows that the wavelengths of light in two media are proportional to the speeds of light in those media.

By Huygens’ principle, the refracted wavefront must be tangent to an arc of radius $\lambda_2$ centered on $h$, say at point $g$. The refracted wavefront must also be tangent to an arc of radius $\lambda_1$ centered on $e$, say at $c$. Then the refracted wavefront must be oriented as shown. Note that $\theta_2$, the angle between the refracted wavefront and the interface, is actually the angle of refraction.

For the right triangles $hce$ and $hcg$ in Fig. 35-3b we may write

$$\sin \theta_1 = \frac{\lambda_1}{hc} \quad \text{(for triangle } hce)$$

and

$$\sin \theta_2 = \frac{\lambda_2}{hc} \quad \text{(for triangle } hcg).$$

Dividing the first of these two equations by the second and using Eq. 35-1, we find

$$\frac{\sin \theta_1}{\sin \theta_2} = \frac{\theta_1}{\theta_2} = \frac{v_1}{v_2}, \quad (35-2)$$

We can define the index of refraction $n$ for each medium as the ratio of the speed of light in vacuum to the speed of light $c$ in the medium. Thus,

$$n = \frac{c}{v} \quad \text{(index of refraction).} \quad (35-3)$$

In particular, for our two media, we have

$$n_1 = \frac{c}{v_1} \quad \text{and} \quad n_2 = \frac{c}{v_2}.$$

We can now rewrite Eq. 35-2 as

$$\frac{\sin \theta_1}{\sin \theta_2} = \frac{c/n_1}{c/n_2} = \frac{n_2}{n_1}$$

or

$$n_1 \sin \theta_1 = n_2 \sin \theta_2 \quad \text{(law of refraction),} \quad (35-4)$$

as introduced in Chapter 33.

**Checkpoint 1**

The figure shows a monochromatic ray of light traveling across parallel interfaces, from an original material $a$, through layers of materials $b$ and $c$, and then back into material $a$. Rank the materials according to the speed of light in them, greatest first.
We have now seen that the wavelength of light changes when the speed of the light changes, as happens when light crosses an interface from one medium into another. Further, the speed of light in any medium depends on the index of refraction of the medium, according to Eq. 35-3. Thus, the wavelength of light in any medium depends on the index of refraction of the medium. Let a certain monochromatic light have wavelength $\lambda$ and speed $c$ in vacuum and wavelength $\lambda_n$ and speed $v$ in a medium with an index of refraction $n$. Now we can rewrite Eq. 35-1 as

$$\lambda_n = \lambda \frac{v}{c}. \quad (35-5)$$

Using Eq. 35-3 to substitute $1/n$ for $v/c$ then yields

$$\lambda_n = \frac{\lambda}{n}. \quad (35-6)$$

This equation relates the wavelength of light in any medium to its wavelength in vacuum: A greater index of refraction means a smaller wavelength.

Next, let $f_n$ represent the frequency of the light in a medium with index of refraction $n$. Then from the general relation of Eq. 16-13 ($v = \lambda f$), we can write

$$f_n = \frac{v}{\lambda_n}.$$ 

Substituting Eqs. 35-3 and 35-6 then gives us

$$f_n = \frac{c/n}{\lambda n} = \frac{c}{\lambda} = f,$$

where $f$ is the frequency of the light in vacuum. Thus, although the speed and wavelength of light in the medium are different from what they are in vacuum, the frequency of the light in the medium is the same as it is in vacuum.

**Phase Difference.** The fact that the wavelength of light depends on the index of refraction via Eq. 35-6 is important in certain situations involving the interference of light waves. For example, in Fig. 35-4, the waves of the rays (that is, the waves represented by the rays) have identical wavelengths $\lambda$ and are initially in phase in air ($n \approx 1$). One of the waves travels through medium 1 of index of refraction $n_1$ and length $L$. The other travels through medium 2 of index of refraction $n_2$ and the same length $L$. When the waves leave the two media, they will have the same wavelength—their wavelength $\lambda$ in air. However, because their wavelengths differed in the two media, the two waves may no longer be in phase.

As we shall discuss soon, this change in the phase difference can determine how the light waves will interfere if they reach some common point.

To find their new phase difference in terms of wavelengths, we first count the number $N_1$ of wavelengths there are in the length $L$ of medium 1. From Eq. 35-6, the wavelength in medium 1 is $\lambda_{n_1} = \lambda/n_1$; so

$$N_1 = \frac{L}{\lambda_{n_1}} = \frac{L n_1}{\lambda}. \quad (35-7)$$

Similarly, we count the number $N_2$ of wavelengths there are in the length $L$ of medium 2, where the wavelength is $\lambda_{n_2} = \lambda/n_2$:

$$N_2 = \frac{L}{\lambda_{n_2}} = \frac{L n_2}{\lambda}. \quad (35-8)$$
To find the new phase difference between the waves, we subtract the smaller of \( N_1 \) and \( N_2 \) from the larger. Assuming \( n_2 > n_1 \), we obtain

\[
N_2 - N_1 = \frac{L n_2}{\lambda} - \frac{L n_1}{\lambda} = \frac{L}{\lambda} (n_2 - n_1).
\]  

Suppose Eq. 35-9 tells us that the waves now have a phase difference of 45.6 wavelengths. That is equivalent to taking the initially in-phase waves and shifting one of them by 45.6 wavelengths. However, a shift of an integer number of wavelengths (such as 45) would put the waves back in phase; so it is only the decimal fraction (here, 0.6) that is important. A phase difference of 45.6 wavelengths is equivalent to an effective phase difference of 0.6 wavelength.

A phase difference of 0.5 wavelength puts two waves exactly out of phase. If the waves had equal amplitudes and were to reach some common point, they would then undergo fully destructive interference, producing darkness at that point. With a phase difference of 0.0 or 1.0 wavelength, they would, instead, undergo fully constructive interference, resulting in brightness at the common point. Our phase difference of 0.6 wavelength is an intermediate situation but closer to fully destructive interference, and the waves would produce a dimly illuminated common point.

We can also express phase difference in terms of radians and degrees, as we have done already. A phase difference of one wavelength is equivalent to phase differences of \( 2\pi \) rad and 360°.

**Path Length Difference.** As we discussed with sound waves in Module 17-3, two waves that begin with some initial phase difference can end up with a different phase difference if they travel through paths with different lengths before coming back together. The key for the waves (whatever their type might be) is the path length difference \( \Delta L \), or more to the point, how \( \Delta L \) compares to the wavelength \( \lambda \) of the waves. From Eqs. 17-23 and 17-24, we know that, for light waves, fully constructive interference (maximum brightness) occurs when

\[
\frac{\Delta L}{\lambda} = 0, 1, 2, \ldots \quad \text{(fully constructive interference),} \quad (35-10)
\]

and that fully destructive interference (darkness) occurs when

\[
\frac{\Delta L}{\lambda} = 0.5, 1.5, 2.5, \ldots \quad \text{(fully destructive interference).} \quad (35-11)
\]

Intermediate values correspond to intermediate interference and thus also illumination.

**Rainbows and Optical Interference**

In Module 33-5, we discussed how the colors of sunlight are separated into a rainbow when sunlight travels through falling raindrops. We dealt with a simplified situation in which a single ray of white light entered a drop. Actually, light waves pass into a drop along the entire side that faces the Sun. Here we cannot discuss the details of how these waves travel through the drop and then emerge, but we can see that different parts of an incoming wave will travel different paths within the drop. That means waves will emerge from the drop with different phases. Thus, we can see that at some angles the emerging light will be in phase and give constructive interference. The rainbow is the result of such constructive interference. For example, the red of the rainbow appears because waves of red light emerge in phase from each raindrop in the direction in which you see that part of the rainbow. The light waves that emerge in other directions from each raindrop have a range of different phases because they take a
range of different paths through each drop. This light is neither bright nor colorful, and so you do not notice it.

If you are lucky and look carefully below a primary rainbow, you can see dimmer colored arcs called *supernumeraries* (Fig. 35-5). Like the main arcs of the rainbow, the supernumeraries are due to waves that emerge from each drop approximately in phase with one another to give constructive interference. If you are very lucky and look very carefully above a secondary rainbow, you might see even more (but even dimmer) supernumeraries. Keep in mind that both types of rainbows and both sets of supernumeraries are naturally occurring examples of optical interference and naturally occurring evidence that light consists of waves.

---

**Sample Problem 35.01  Phase difference of two waves due to difference in refractive indexes**

In Fig. 35-4, the two light waves that are represented by the rays have wavelength 550.0 nm before entering media 1 and 2. They also have equal amplitudes and are in phase. Medium 1 is now just air, and medium 2 is a transparent plastic layer of index of refraction 1.600 and thickness 2.600 μm.

(a) What is the phase difference of the emerging waves in wavelengths, radians, and degrees? What is their effective phase difference (in wavelengths)?

**Key Idea**

The phase difference of two light waves can change if they travel through different media, with different indexes of refraction. The reason is that their wavelengths are different in the different media. We can calculate the change in phase difference by counting the number of wavelengths that fits into each medium and then subtracting those numbers.

**Calculations:** When the path lengths of the waves in the two media are identical, Eq. 35-9 gives the result of the subtraction. Here we have \( n_1 = 1.000 \) (for the air), \( n_2 = 1.600 \), \( L = 2.600 \mu m \), and \( \lambda = 550.0 \) nm. Thus, Eq. 35-9 yields

\[
N_2 - N_1 = \frac{L}{\lambda} (n_2 - n_1)
\]

\[
= \frac{2.600 \times 10^{-6} \text{ m}}{5.500 \times 10^{-7} \text{ m}} (1.600 - 1.000)
\]

\[
= 2.84.
\]

Thus, the phase difference of the emerging waves is 2.84 wavelengths. Because 1.0 wavelength is equivalent to \( 2\pi \text{ rad} \) and \( 360^\circ \), you can show that this phase difference is equivalent to

\[
\text{phase difference} = 17.8 \text{ rad} \approx 1020^\circ.
\]

(Answer)

The effective phase difference is the decimal part of the actual phase difference *expressed in wavelengths*. Thus, we have

\[
\text{effective phase difference} = 0.84 \text{ wavelength}.
\]

(Answer)

You can show that this is equivalent to 5.3 rad and about \( 300^\circ \). *Caution: We do not find the effective phase difference by taking the decimal part of the actual phase difference as expressed in radians or degrees. For example, we do not take 0.8 rad from the actual phase difference of 17.8 rad.*

(b) If the waves reached the same point on a distant screen, what type of interference would they produce?

**Reasoning:** We need to compare the effective phase difference of the waves with the phase differences that give the extreme types of interference. Here the effective phase difference of 0.84 wavelength is between 0.5 wavelength (for fully destructive interference, or the darkest possible result) and 1.0 wavelength (for fully constructive interference, or the brightest possible result), but closer to 1.0 wavelength. Thus, the waves would produce intermediate interference that is closer to fully constructive interference—they would produce a relatively bright spot.

---

**Checkpoint 2**

The light waves of the rays in Fig. 35-4 have the same wavelength and amplitude and are initially in phase. (a) If 7.60 wavelengths fit within the length of the top material and 5.50 wavelengths fit within that of the bottom material, which material has the greater index of refraction? (b) If the rays are angled slightly so that they meet at the same point on a distant screen, will the interference there result in the brightest possible illumination, bright intermediate illumination, dark intermediate illumination, or darkness?

---

Additional examples, video, and practice available at WileyPLUS
35–2 YOUNG’S INTERFERENCE EXPERIMENT

Learning Objectives

After reading this module, you should be able to . . .

35.13 Describe the diffraction of light by a narrow slit and the effect of narrowing the slit.

35.14 With sketches, describe the production of the interference pattern in a double-slit interference experiment using monochromatic light.

35.15 Identify that the phase difference between two waves can change if the waves travel along paths of different lengths, as in the case of Young’s experiment.

35.16 In a double-slit experiment, apply the relationship between the path length difference \( \Delta L \) and the wavelength \( \lambda \), and then interpret the result in terms of interference (maximum brightness, intermediate brightness, and darkness).

35.17 For a given point in a double-slit interference pattern, express the path length difference \( \Delta L \) of the rays reaching that point in terms of the slit separation \( d \) and the angle \( \theta \) to that point.

35.18 In a Young’s experiment, apply the relationships between the slit separation \( d \), the light wavelength \( \lambda \), and the angles \( \theta \) to the minima (dark fringes) and to the maxima (bright fringes) in the interference pattern.

35.19 Sketch the double-slit interference pattern, identifying what lies at the center and what the various bright and dark fringes are called (such as “first side maximum” and “third order”).

35.20 Apply the relationship between the distance \( D \) between a double-slit screen and a viewing screen, the angle \( \theta \) to a point in the interference pattern, and the distance \( y \) to that point from the pattern’s center.

35.21 For a double-slit interference pattern, identify the effects of changing \( d \) or \( \lambda \) and also identify what determines the angular limit to the pattern.

35.22 For a transparent material placed over one slit in a Young’s experiment, determine the thickness or index of refraction required to shift a given fringe to the center of the interference pattern.

Key Ideas

- In Young’s interference experiment, light passing through a single slit falls on two slits in a screen. The light leaving these slits flares out (by diffraction), and interference occurs in the region beyond the screen. A fringe pattern, due to the interference, forms on a viewing screen.

- The conditions for maximum and minimum intensity are

  \[
  d \sin \theta = m\lambda, \quad \text{for } m = 0, 1, 2, \ldots \quad \text{(maxima — bright fringes)},
  \]
  \[
  d \sin \theta = (m + \frac{1}{2})\lambda, \quad \text{for } m = 0, 1, 2, \ldots \quad \text{(minima — dark fringes)},
  \]

where \( \theta \) is the angle the light path makes with a central axis and \( d \) is the slit separation.

Diffraction

In this module we shall discuss the experiment that first proved that light is a wave. To prepare for that discussion, we must introduce the idea of diffraction of waves, a phenomenon that we explore much more fully in Chapter 36. Its essence is this: If a wave encounters a barrier that has an opening of dimensions similar to the wavelength, the part of the wave that passes through the opening will flare (spread) out — will diffract — into the region beyond the barrier. The flaring is consistent with the spreading of wavelets in the Huygens construction of Fig. 35–2. Diffraction occurs for waves of all types, not just light waves; Fig. 35-6 shows the diffraction of water waves traveling across the surface of water in a shallow tank. Similar diffraction of ocean waves through openings in a barrier can actually increase the erosion of a beach the barrier is intended to protect.
Figure 35-7 shows the situation schematically for an incident plane wave of wavelength $\lambda$ encountering a slit that has width $a = 6.0\lambda$ and extends into and out of the page. The part of the wave that passes through the slit flares out on the far side. Figures 35-7b (with $a = 3.0\lambda$) and 35-7c ($a = 1.5\lambda$) illustrate the main feature of diffraction: the narrower the slit, the greater the diffraction.

Diffraction limits geometrical optics, in which we represent an electromagnetic wave with a ray. If we actually try to form a ray by sending light through a narrow slit, or through a series of narrow slits, diffraction will always defeat our effort because it always causes the light to spread. Indeed, the narrower we make the slits (in the hope of producing a narrower beam), the greater the spreading is. Thus, geometrical optics holds only when slits or other apertures that might be located in the path of light do not have dimensions comparable to or smaller than the wavelength of the light.

**Young's Interference Experiment**

In 1801, Thomas Young experimentally proved that light is a wave, contrary to what most other scientists then thought. He did so by demonstrating that light undergoes interference, as do water waves, sound waves, and waves of all other types. In addition, he was able to measure the average wavelength of sunlight; his value, 570 nm, is impressively close to the modern accepted value of 555 nm. We shall here examine Young’s experiment as an example of the interference of light waves.

Figure 35-8 gives the basic arrangement of Young’s experiment. Light from a distant monochromatic source illuminates slit $S_0$ in screen $A$. The emerging light then spreads via diffraction to illuminate two slits $S_1$ and $S_2$ in screen $B$. Diffraction of the light by these two slits sends overlapping circular waves into

![Figure 35-8](image-url)
the region beyond screen $B$, where the waves from one slit interfere with the waves from the other slit.

The “snapshot” of Fig. 35-8 depicts the interference of the overlapping waves. However, we cannot see evidence for the interference except where a viewing screen $C$ intercepts the light. Where it does so, points of interference maxima form visible bright rows — called bright bands, bright fringes, or (loosely speaking) maxima — that extend across the screen (into and out of the page in Fig. 35-8). Dark regions — called dark bands, dark fringes, or (loosely speaking) minima — result from fully destructive interference and are visible between adjacent pairs of bright fringes. (Maxima and minima more properly refer to the center of a band.) The pattern of bright and dark fringes on the screen is called an interference pattern. Figure 35-9 is a photograph of part of the interference pattern that would be seen by an observer standing to the left of screen $C$ in the arrangement of Fig. 35-8.

**Locating the Fringes**

Light waves produce fringes in a Young’s double-slit interference experiment, as it is called, but what exactly determines the locations of the fringes? To answer, we shall use the arrangement in Fig. 35-10a. There, a plane wave of monochromatic light is incident on two slits $S_1$ and $S_2$ in screen $B$; the light diffracts through the slits and produces an interference pattern on screen $C$. We draw a central axis from the point halfway between the slits to screen $C$ as a reference. We then pick, for discussion, an arbitrary point $P$ on the screen, at angle $\theta$ to the central axis. This point intercepts the wave of ray $r_1$ from the bottom slit and the wave of ray $r_2$ from the top slit.

**Path Length Difference.** These waves are in phase when they pass through the two slits because there they are just portions of the same incident wave. However, once they have passed the slits, the two waves must travel different distances to reach $P$. We saw a similar situation in Module 17-3 with sound waves and concluded that

The phase difference between two waves can change if the waves travel paths of different lengths.

The change in phase difference is due to the path length difference $\Delta L$ in the paths taken by the waves. Consider two waves initially exactly in phase, traveling along paths with a path length difference $\Delta L$, and then passing through some common point. When $\Delta L$ is zero or an integer number of wavelengths, the waves arrive at the common point exactly in phase and they interfere fully constructively there. If that is true for the waves of rays $r_1$ and $r_2$ in Fig. 35-10, then

![Figure 35-10](image)
Angle. We can specify where each bright fringe and each dark fringe is located on the screen by giving the angle \( \theta \) from the central axis to that fringe. To find \( \theta \), we must relate it to \( \Delta L \). We start with Fig. 35-10a by finding a point \( b \) along ray \( r_1 \) such that the path length from \( b \) to \( P \) equals the path length from \( S_2 \) to \( P \). Then the path length difference \( \Delta L \) between the two rays is the distance from \( S_1 \) to \( b \).

The relation between this \( S_1 \)-to-\( b \) distance and \( \theta \) is complicated, but we can simplify it considerably if we arrange for the distance \( D \) from the slits to the screen to be much greater than the slit separation \( d \). Then we can approximate rays \( r_1 \) and \( r_2 \) as being parallel to each other and at angle \( \theta \) to the central axis (Fig. 35-10b). We can also approximate the triangle formed by \( S_1, S_2, \) and \( b \) as being a right triangle, and approximate the angle inside that triangle at \( S_2 \) as being \( \theta \). Then, for that triangle, \( \sin \theta = \Delta L/d \) and thus

\[
\Delta L = d \sin \theta \quad \text{(path length difference).} \tag{35-12}
\]

For a bright fringe, we saw that \( \Delta L \) must be either zero or an integer number of wavelengths. Using Eq. 35-12, we can write this requirement as

\[
\Delta L = d \sin \theta = (\text{integer})(\lambda), \tag{35-13}
\]

or as

\[
d \sin \theta = m\lambda, \quad \text{for } m = 0, 1, 2, \ldots \quad \text{(maxima—bright fringes).} \tag{35-14}
\]

For a dark fringe, \( \Delta L \) must be an odd multiple of half a wavelength. Again using Eq. 35-12, we can write this requirement as

\[
\Delta L = d \sin \theta = (\text{odd number})\left(\frac{1}{2}\lambda\right), \tag{35-15}
\]

or as

\[
d \sin \theta = (m + \frac{1}{2})\lambda, \quad \text{for } m = 0, 1, 2, \ldots \quad \text{(minima—dark fringes).} \tag{35-16}
\]

With Eqs. 35-14 and 35-16, we can find the angle \( \theta \) to any fringe and thus locate that fringe; further, we can use the values of \( m \) to label the fringes. For the value and label \( m = 0 \), Eq. 35-14 tells us that a bright fringe is at \( \theta = 0 \) and thus on the central axis. This central maximum is the point at which waves arriving from the two slits have a path length difference \( \Delta L = 0 \), hence zero phase difference.

For, say, \( m = 2 \), Eq. 35-14 tells us that bright fringes are at the angle

\[
\theta = \sin^{-1}\left(\frac{2\lambda}{d}\right)
\]

above and below the central axis. Waves from the two slits arrive at these two fringes with \( \Delta L = 2\lambda \) and with a phase difference of two wavelengths. These fringes are said to be the second-order bright fringes (meaning \( m = 2 \)) or the second side maxima (the second maxima to the side of the central maximum), or
they are described as being the second bright fringes from the central maximum.

For \( m = 1 \), Eq. 35-16 tells us that dark fringes are at the angle

\[
\theta = \sin^{-1}\left(\frac{1.5\lambda}{d}\right)
\]

above and below the central axis. Waves from the two slits arrive at these two fringes with \( \Delta L = 1.5\lambda \) and with a phase difference, in wavelengths, of 1.5. These fringes are called the second-order dark fringes or second minima because they are the second dark fringes to the side of the central axis. (The first dark fringes, or first minima, are at locations for which \( m = 0 \) in Eq. 35-16.)

**Nearby Screen.** We derived Eqs. 35-14 and 35-16 for the situation \( D \gg d \). However, they also apply if we place a converging lens between the slits and the viewing screen and then move the viewing screen closer to the slits, to the focal point of the lens. (The screen is then said to be in the focal plane of the lens; that is, it is in the plane perpendicular to the central axis at the focal point.) One property of a converging lens is that it focuses all rays that are parallel to one another to the same point on its focal plane. Thus, the rays that now arrive at any point on the screen (in the focal plane) were exactly parallel (rather than approximately) when they left the slits. They are like the initially parallel rays in Fig. 34-14a that are directed to a point (the focal point) by a lens.

**Checkpoint 3**

In Fig. 35-10a, what are \( \Delta L \) (as a multiple of the wavelength) and the phase difference (in wavelengths) for the two rays if point \( P \) is (a) a third side maximum and (b) a third minimum?

**Sample Problem 35.02  Double-slit interference pattern**

What is the distance on screen \( C \) in Fig. 35-10a between adjacent maxima near the center of the interference pattern? The wavelength \( \lambda \) of the light is 546 nm, the slit separation \( d \) is 0.12 mm, and the slit–screen separation \( D \) is 55 cm. Assume that \( \theta \) in Fig. 35-10 is small enough to permit use of the approximations \( \sin \theta \approx \tan \theta = \theta \), in which \( \theta \) is expressed in radian measure.

**KEY IDEAS**

1. First, let us pick a maximum with a low value of \( m \) to ensure that it is near the center of the pattern. Then, from the geometry of Fig. 35-10a, the maximum’s vertical distance \( y_m \) from the center of the pattern is related to its angle \( \theta \) from the central axis by

   \[
   \tan \theta \approx \theta = \frac{y_m}{D}.
   \]

2. From Eq. 35-14, this angle \( \theta \) for the \( m \)th maximum is given by

   \[
   \sin \theta \approx \theta = \frac{m\lambda}{d}.
   \]

**Calculations:** If we equate our two expressions for angle \( \theta \) and then solve for \( y_m \), we find

\[
y_m = \frac{m\lambda D}{d}. \tag{35-17}
\]

For the next maximum as we move away from the pattern’s center, we have

\[
y_{m+1} = \frac{(m + 1)\lambda D}{d}. \tag{35-18}
\]

We find the distance between these adjacent maxima by subtracting Eq. 35-17 from Eq. 35-18:

\[
\Delta y = y_{m+1} - y_m = \frac{\lambda D}{d} = \frac{(546 \times 10^{-9} \text{ m})(55 \times 10^{-2} \text{ m})}{0.12 \times 10^{-3} \text{ m}} = 2.50 \times 10^{-3} \text{ m} \approx 2.5 \text{ mm}. \quad \text{(Answer)}
\]

As long as \( d \) and \( \theta \) in Fig. 35-10a are small, the separation of the interference fringes is independent of \( m \); that is, the fringes are evenly spaced.
Sample Problem 35.03  Double-slit interference pattern with plastic over one slit

A double-slit interference pattern is produced on a screen, as in Fig. 35-10; the light is monochromatic at a wavelength of 600 nm. A strip of transparent plastic with index of refraction \( n = 1.50 \) is to be placed over one of the slits. Its presence changes the interference between light waves from the two slits, causing the interference pattern to be shifted across the screen from the original pattern. Figure 35-11a shows the original locations of the central bright fringe \((m = 0)\) and the first bright fringes \((m = 1)\) above and below the central fringe. The purpose of the plastic is to shift the pattern upward so that the lower \(m = 1\) bright fringe is shifted to the center of the pattern. Should the plastic be placed over the top slit (as arbitrarily drawn in Fig. 35-11b) or the bottom slit, and what thickness \(L\) should it have?

**KEY IDEA**

The interference at a point on the screen depends on the phase difference of the light rays arriving from the two slits. The light rays are in phase at the slits because they derive from the same wave, but their relative phase can shift on the way to the screen due to (1) a difference in the length of the paths they follow and (2) a difference in the number of their internal wavelengths \(\lambda_n\) in the materials through which they pass. The first condition applies to any off-center point, and the second condition applies when the plastic covers one of the slits.

**Path length difference:**  Figure 35-11a shows rays \(r_1\) and \(r_2\) along which waves from the two slits travel to reach the lower \(m = 1\) bright fringe. Those waves start in phase at the slits but arrive at the fringe with a phase difference of exactly 1 wavelength. To remind ourselves of this main characteristic of the fringe, let us call it the \(1\lambda\) fringe. The one-wavelength phase difference is due to the one-wavelength path length difference between the rays reaching the fringe; that is, there is exactly one more wavelength along ray \(r_2\) than along \(r_1\).

Figure 35-11b shows the \(1\lambda\) fringe shifted up to the center of the pattern with the plastic strip over the top slit (we still do not know whether the plastic should be there or over the bottom slit). The figure also shows the new orientations of rays \(r_1\) and \(r_2\) to reach that fringe. There still must be one more wavelength along \(r_2\) than along \(r_1\) (because they still produce the \(1\lambda\) fringe), but now the path length difference between those rays is zero, as we can tell from the geometry of Fig. 35-11b. However, \(r_2\) now passes through the plastic.

**Internal wavelength:**  The wavelength \(\lambda_n\) of light in a material with index of refraction \(n\) is smaller than the wavelength in vacuum, as given by Eq. 35-6 \((\lambda_n = \lambda/n)\). Here, this means that the wavelength of the light is smaller in the plastic than in the air. Thus, the ray that passes through the plastic will have more wavelengths along it than the ray that passes through only air—so we do get the one extra wavelength we need along ray \(r_2\) by placing the plastic over the top slit, as drawn in Fig. 35-11b.

**Thickness:**  To determine the required thickness \(L\) of the plastic, we first note that the waves are initially in phase and travel equal distances \(L\) through different materials (plastic and air). Because we know the phase difference and require \(L\), we use Eq. 35-9,

\[
N_2 - N_1 = \frac{L}{\lambda}(n_2 - n_1) \quad (35-19)
\]

We know that \(N_2 - N_1 = 1\) for a phase difference of one wavelength, \(n_2 = 1.50\) for the plastic in front of the top slit, \(n_1 = 1.00\) for the air in front of the bottom slit, and \(\lambda = 600 \times 10^{-9}\) m. Then Eq. 35-19 tells us that, to shift the lower \(m = 1\) bright fringe up to the center of the interference pattern, the plastic must have the thickness

\[
L = \frac{\lambda(N_2 - N_1)}{n_2 - n_1} = \frac{(600 \times 10^{-9}\text{ m})(1)}{1.50 - 1.00}
= 1.2 \times 10^{-6}\text{ m.} \quad (\text{Answer})
\]

The difference in indexes causes a phase shift between the rays, moving the \(1\lambda\) fringe upward.

Figure 35-11  (a) Arrangement for two-slit interference (not to scale). The locations of three bright fringes (or maxima) are indicated.  (b) A strip of plastic covers the top slit. We want the \(1\lambda\) fringe to be at the center of the pattern.
35-3 INTERFERENCE AND DOUBLE-SLIT INTENSITY

Learning Objectives

After reading this module, you should be able to . . .

35.23 Distinguish between coherent and incoherent light.
35.24 For two light waves arriving at a common point, write expressions for their electric field components as functions of time and a phase constant.
35.25 Identify that the phase difference between two waves determines their interference.
35.26 For a point in a double-slit interference pattern, calculate the intensity in terms of the phase difference of the arriving waves and relate that phase difference to the angle \( \theta \) locating that point in the pattern.
35.27 Use a phasor diagram to find the resultant wave (amplitude and phase constant) of two or more light waves arriving at a common point and use that result to determine the intensity.
35.28 Apply the relationship between a light wave’s angular frequency \( \omega \) and the angular speed \( \omega \) of the phasor representing the wave.

Key Ideas

• If two light waves that meet at a point are to interfere perceptibly, the phase difference between them must remain constant with time; that is, the waves must be coherent. When two coherent waves meet, the resulting intensity may be found by using phasors.

• In Young’s interference experiment, two waves, each with intensity \( I_0 \), yield a resultant wave of intensity \( I \) at the viewing screen, with

\[
I = 4I_0 \cos^2 \frac{1}{2} \phi, \quad \text{where} \quad \phi = \frac{2\pi d}{\lambda} \sin \theta.
\]

Coherence

For the interference pattern to appear on viewing screen \( C \) in Fig. 35-8, the light waves reaching any point \( P \) on the screen must have a phase difference that does not vary in time. That is the case in Fig. 35-8 because the waves passing through slits \( S_1 \) and \( S_2 \) are portions of the single light wave that illuminates the slits. Because the phase difference remains constant, the light from slits \( S_1 \) and \( S_2 \) is said to be completely coherent.

Sunlight and Fingernails. Direct sunlight is partially coherent; that is, sunlight waves intercepted at two points have a constant phase difference only if the points are very close. If you look closely at your fingernail in bright sunlight, you can see a faint interference pattern called speckle that causes the nail to appear to be covered with specks. You see this effect because light waves scattering from very close points on the nail are sufficiently coherent to interfere with one another at your eye. The slits in a double-slit experiment, however, are not close enough, and in direct sunlight, the light at the slits would be incoherent. To get coherent light, we would have to send the sunlight through a single slit as in Fig. 35-8; because that single slit is small, light that passes through it is coherent. In addition, the smallness of the slit causes the coherent light to spread via diffraction to illuminate both slits in the double-slit experiment.

Incoherent Sources. If we replace the double slits with two similar but independent monochromatic light sources, such as two fine incandescent wires, the phase difference between the waves emitted by the sources varies rapidly and randomly. (This occurs because the light is emitted by vast numbers of atoms in the wires, acting randomly and independently for extremely short times—of the order of nanoseconds.) As a result, at any given point on the viewing screen, the interference between the waves from the two sources varies rapidly and randomly between fully constructive and fully destructive. The eye (and most common optical detectors) cannot follow such changes, and no interference pattern can be seen. The fringes disappear, and the screen is seen as being uniformly illuminated.
**Coherent Source.** A laser differs from common light sources in that its atoms emit light in a cooperative manner, thereby making the light coherent. Moreover, the light is almost monochromatic, is emitted in a thin beam with little spreading, and can be focused to a width that almost matches the wavelength of the light.

**Intensity in Double-Slit Interference**

Equations 35-14 and 35-16 tell us how to locate the maxima and minima of the double-slit interference pattern on screen $C$ of Fig. 35-10 as a function of the angle $\theta$ in that figure. Here we wish to derive an expression for the intensity $I$ of the fringes as a function of $\theta$.

The light leaving the slits is in phase. However, let us assume that the light waves from the two slits are not in phase when they arrive at point $P$. Instead, the electric field components of those waves at point $P$ are not in phase and vary with time as

$$E_1 = E_0 \sin \omega t$$

and

$$E_2 = E_0 \sin(\omega t + \phi),$$

where $\omega$ is the angular frequency of the waves and $\phi$ is the phase constant of wave $E_2$. Note that the two waves have the same amplitude $E_0$ and a phase difference of $\phi$. Because that phase difference does not vary, the waves are coherent. We shall show that these two waves will combine at $P$ to produce an intensity $I$ given by

$$I = 4I_0 \cos^2 \frac{1}{2} \phi,$$

and that

$$\phi = \frac{2\pi d}{\lambda} \sin \theta.$$

In Eq. 35-22, $I_0$ is the intensity of the light that arrives on the screen from one slit when the other slit is temporarily covered. We assume that the slits are so narrow in comparison to the wavelength that this single-slit intensity is essentially uniform over the region of the screen in which we wish to examine the fringes.

Equations 35-22 and 35-23, which together tell us how the intensity $I$ of the fringe pattern varies with the angle $\theta$ in Fig. 35-10, necessarily contain information about the location of the maxima and minima. Let us see if we can extract that information to find equations about those locations.

**Maxima.** Study of Eq. 35-22 shows that intensity maxima will occur when

$$\frac{1}{2} \phi = m\pi, \quad \text{for } m = 0, 1, 2, \ldots.$$  

(35-24)

If we put this result into Eq. 35-23, we find

$$2m\pi = \frac{2\pi d}{\lambda} \sin \theta, \quad \text{for } m = 0, 1, 2, \ldots$$

or

$$d \sin \theta = m\lambda, \quad \text{for } m = 0, 1, 2, \ldots$$  

(maxima),

(35-25)

which is exactly Eq. 35-14, the expression that we derived earlier for the locations of the maxima.

**Minima.** The minima in the fringe pattern occur when

$$\frac{1}{2} \phi = (m + \frac{1}{2})\pi, \quad \text{for } m = 0, 1, 2, \ldots.$$  

(35-26)

If we combine this relation with Eq. 35-23, we are led at once to

$$d \sin \theta = (m + \frac{1}{2})\lambda, \quad \text{for } m = 0, 1, 2, \ldots$$  

(minima),

(35-27)
which is just Eq. 35-16, the expression we derived earlier for the locations of the fringe minima.

Figure 35-12, which is a plot of Eq. 35-22, shows the intensity of double-slit interference pattern as a function of the phase difference between the waves when they arrive from the two slits. \( I_0 \) is the (uniform) intensity that would appear on the screen if one slit were covered. The average intensity of the fringe pattern is \( 2I_0 \), and the maximum intensity (for coherent light) is \( 4I_0 \).

Proof of Eqs. 35-22 and 35-23

We shall combine the electric field components \( E_1 \) and \( E_2 \), given by Eqs. 35-20 and 35-21, respectively, by the method of phasors as is discussed in Module 16-6. In Fig. 35-13a, the waves with components \( E_1 \) and \( E_2 \) are represented by phasors of magnitude \( E_0 \) that rotate around the origin at angular speed \( \omega \). The values of \( E_1 \) and \( E_2 \) at any time are the projections of the corresponding phasors on the vertical axis. Figure 35-13a shows the phasors and their projections at an arbitrary time \( t \). Consistent with Eqs. 35-20 and 35-21, the phasor for \( E_1 \) has a rotation angle \( \omega t \) and the phasor for \( E_2 \) has a rotation angle \( \omega t + \phi \) (it is phase-shifted ahead of \( E_1 \)). As each phasor rotates, its projection on the vertical axis varies with time in the same way that the sinusoidal functions of Eqs. 35-20 and 35-21 vary with time.

To combine the field components \( E_1 \) and \( E_2 \) at any point \( P \) in Fig. 35-10, we add their phasors vectorially, as shown in Fig. 35-13b. The magnitude of the vector sum is the amplitude \( E \) of the resultant wave at point \( P \), and that wave has a certain phase constant \( \beta \). To find the amplitude \( E \) in Fig. 35-13b, we first note that the two angles marked \( \beta \) are equal because they are opposite equal-length sides of a triangle. From the theorem (for triangles) that an exterior angle (here \( \phi \), as shown in Fig. 35-13b) is equal to the sum of the two opposite interior angles (here that sum is \( \beta + \beta \)), we see that \( \beta = \frac{1}{2} \phi \). Thus, we have

\[
E = 2(E_0 \cos \beta)
= 2E_0 \cos \frac{1}{2} \phi.
\]  

\( (35-28) \)
If we square each side of this relation, we obtain

\[ E^2 = 4E_0^2 \cos^2 \frac{1}{2} \phi. \]  

(35-29)

**Intensity.** Now, from Eq. 33-24, we know that the intensity of an electromagnetic wave is proportional to the square of its amplitude. Therefore, the waves we are combining in Fig. 35-13b, whose amplitudes are \( E_0 \), each has an intensity \( I_0 \) that is proportional to \( E_0^2 \), and the resultant wave, with amplitude \( E \), has an intensity \( I \) that is proportional to \( E^2 \). Thus,

\[ \frac{I}{I_0} = \frac{E^2}{E_0^2}. \]

Substituting Eq. 35-29 into this equation and rearranging then yield

\[ I = 4I_0 \cos^2 \frac{1}{2} \phi, \]

which is Eq. 35-22, which we set out to prove.

We still must prove Eq. 35-23, which relates the phase difference \( \phi \) between the waves arriving at any point \( P \) on the screen of Fig. 35-10 to the angle \( \theta \) that serves as a locator of that point.

The phase difference \( \phi \) in Eq. 35-21 is associated with the path length difference \( S_{1b} \) in Fig. 35-10b. If \( S_{1b} = \frac{1}{2} \lambda \), then \( \phi = \pi \); if \( S_{1b} = \lambda \), then \( \phi = 2\pi \), and so on. This suggests

\[ \left( \frac{\text{phase difference}}{\text{path length difference}} \right) = \frac{2\pi}{\lambda} \left( \frac{\text{path length difference}}{\text{path length difference}} \right). \]  

(35-30)

The path length difference \( S_{1b} \) in Fig. 35-10b is \( d \sin \theta \) (a leg of the right triangle); so Eq. 35-30 for the phase difference between the two waves arriving at point \( P \) on the screen becomes

\[ \phi = \frac{2\pi d}{\lambda} \sin \theta, \]

which is Eq. 35-23, the other equation that we set out to prove to relate \( \phi \) to the angle \( \theta \) that locates \( P \).

**Combining More Than Two Waves**

In a more general case, we might want to find the resultant of more than two sinusoidally varying waves at a point. Whatever the number of waves is, our general procedure is this:

1. Construct a series of phasors representing the waves to be combined. Draw them end to end, maintaining the proper phase relations between adjacent phasors.
2. Construct the vector sum of this array. The length of this vector sum gives the amplitude of the resultant phasor. The angle between the vector sum and the first phasor is the phase of the resultant with respect to this first phasor. The projection of this vector-sum phasor on the vertical axis gives the time variation of the resultant wave.

**Checkpoint 4**

Each of four pairs of light waves arrives at a certain point on a screen. The waves have the same wavelength. At the arrival point, their amplitudes and phase differences are (a) \( 2E_0, 6E_0 \), and \( \pi \) rad; (b) \( 3E_0, 5E_0 \), and \( \pi \) rad; (c) \( 9E_0, 7E_0 \), and \( 3\pi \) rad; (d) \( 2E_0, 2E_0 \), and \( 0 \) rad. Rank the four pairs according to the intensity of the light at the arrival point, greatest first. (Hint: Draw phasors.)
Sample Problem 35.04 Combining three light waves by using phasors

Three light waves combine at a certain point where their electric field components are

\[ E_1 = E_0 \sin \omega t, \]
\[ E_2 = E_0 \sin(\omega t + 60^\circ), \]
\[ E_3 = E_0 \sin(\omega t - 30^\circ). \]

Find their resultant component \( E(t) \) at that point.

**KEY IDEA**

The resultant wave is

\[ E(t) = E_1(t) + E_2(t) + E_3(t). \]

We can use the method of phasors to find this sum, and we are free to evaluate the phasors at any time \( t \).

**Calculations:** To simplify the solution, we choose \( t = 0 \), for which the phasors representing the three waves are shown in Fig. 35-14. We can add these three phasors either directly on a vector-capable calculator or by components. For the component approach, we first write the sum of their horizontal components as

\[ \sum E_h = E_0 \cos 0 + E_0 \cos 60^\circ + E_0 \cos(-30^\circ) = 2.37E_0. \]

The sum of their vertical components, which is the value of \( E \) at \( t = 0 \), is

\[ \sum E_v = E_0 \sin 0 + E_0 \sin 60^\circ + E_0 \sin(-30^\circ) = 0.366E_0. \]

The resultant wave \( E(t) \) thus has an amplitude \( E_R \) of

\[ E_R = \sqrt{(2.37E_0)^2 + (0.366E_0)^2} = 2.4E_0, \]

and a phase angle \( \beta \) relative to the phasor representing \( E_1 \) of

\[ \beta = \tan^{-1} \left( \frac{0.366E_0}{2.37E_0} \right) = 8.8^\circ. \]

We can now write, for the resultant wave \( E(t) \),

\[ E = E_R \sin(\omega t + \beta) = 2.4E_0 \sin(\omega t + 8.8^\circ). \]

(Answer)

Be careful to interpret the angle \( \beta \) correctly in Fig. 35-14: It is the constant angle between \( E_R \) and the phasor representing \( E_1 \) as the four phasors rotate as a single unit around the origin. The angle between \( E_R \) and the horizontal axis in Fig. 35-14 does not remain equal to \( \beta \).

**Figure 35-14** Three phasors, representing waves with equal amplitudes \( E_0 \) and with phase constants \( 0^\circ \), \( 60^\circ \), and \( -30^\circ \), shown at time \( t = 0 \). The phasors combine to give a resultant phasor with magnitude \( E_R \), at angle \( \beta \).

Additional examples, video, and practice available at WileyPLUS

35-4 INTERFERENCE FROM THIN FILMS

**Learning Objectives**

After reading this module, you should be able to . . .

35.29 Sketch the setup for thin-film interference, showing the incident ray and reflected rays (perpendicular to the film but drawn slightly slanted for clarity) and identifying the thickness and the three indexes of refraction.

35.30 Identify the condition in which a reflection can result in a phase shift, and give the value of that phase shift.

35.31 Identify the three factors that determine the interference of the reflected waves: reflection shifts, path length difference, and internal wavelength (set by the film’s index of refraction).

35.32 For a thin film, use the reflection shifts and the desired result (the reflected waves are in phase or out of phase, or the transmitted waves are in phase or out of phase) to determine and then apply the necessary equation relating the thickness \( L \), the wavelength \( \lambda \) (measured in air), and the index of refraction \( n \) of the film.

35.33 For a very thin film in air (with thickness much less than the wavelength of visible light), explain why the film is always dark.

35.34 At each end of a thin film in the form of a wedge, determine and then apply the necessary equation relating the thickness \( L \), the wavelength \( \lambda \) (measured in air), and the index of refraction \( n \) of the film, and then count the number of bright bands and dark bands across the film.
Key Ideas

- When light is incident on a thin transparent film, the light waves reflected from the front and back surfaces interfere. For near-normal incidence, the wavelength conditions for maximum and minimum intensity of the light reflected from a film in air are

\[ 2L = (m + \frac{1}{2}) \frac{n_2 \lambda}{n_1}, \quad \text{for} \quad m = 0, 1, 2, \ldots \]

(maxima — bright film in air),

\[ 2L = m \frac{\lambda}{n_2}, \quad \text{for} \quad m = 0, 1, 2, \ldots \]

(minima — dark film in air),

where \( n_2 \) is the index of refraction of the film, \( L \) is its thickness, and \( \lambda \) is the wavelength of the light in air.

- If a film is sandwiched between media other than air, these equations for bright and dark films may be interchanged, depending on the relative indexes of refraction.

- If the light incident at an interface between media with different indexes of refraction is in the medium with the smaller index of refraction, the reflection causes a phase change of \( \pi \) rad, or half a wavelength, in the reflected wave. Otherwise, there is no phase change due to the reflection. Refraction causes no phase shift.

Interference from Thin Films

The colors on a sunlit soap bubble or an oil slick are caused by the interference of light waves reflected from the front and back surfaces of a thin transparent film. The thickness of the soap or oil film is typically of the order of magnitude of the wavelength of the (visible) light involved. (Greater thicknesses spoil the coherence of the light needed to produce the colors due to interference.)

Figure 35-15 shows a thin transparent film of uniform thickness \( L \) and index of refraction \( n_2 \), illuminated by bright light of wavelength \( \lambda \) from a distant point source. For now, we assume that air lies on both sides of the film and thus that \( n_1 = n_3 = 1 \) in Fig. 35-15. For simplicity, we also assume that the light rays are almost perpendicular to the film (\( \theta \approx 0 \)). We are interested in whether the film is bright or dark to an observer viewing it almost perpendicularly. (Since the film is brightly illuminated, how could it possibly be dark? You will see.)

The incident light, represented by ray \( i \), intercepts the front (left) surface of the film at point \( a \) and undergoes both reflection and refraction there. The reflected ray \( r_1 \) is intercepted by the observer’s eye. The refracted light crosses the film to point \( b \) on the back surface, where it undergoes both reflection and refraction. The light reflected at \( b \) crosses back through the film to point \( c \), where it undergoes both reflection and refraction. The light refracted at \( c \), represented by ray \( r_2 \), is intercepted by the observer’s eye.

If the light waves of rays \( r_1 \) and \( r_2 \) are exactly in phase at the eye, they produce an interference maximum and region \( ac \) on the film is bright to the observer. If they are exactly out of phase, they produce an interference minimum and region \( ac \) is dark to the observer, even though it is illuminated. If there is some intermediate phase difference, there are intermediate interference and brightness.

The Key. Thus, the key to what the observer sees is the phase difference between the waves of rays \( r_1 \) and \( r_2 \). Both rays are derived from the same ray \( i \), but the path involved in producing \( r_2 \) involves light traveling twice across the film (\( ab \) and then \( bc \)), whereas the path involved in producing \( r_1 \) involves no travel through the film. Because \( \theta \) is about zero, we approximate the path length difference between the waves of \( r_1 \) and \( r_2 \) as \( 2L \). However, to find the phase difference between the waves, we cannot just find the number of wavelengths \( \lambda \) that is equivalent to a path length difference of \( 2L \). This simple approach is impossible for two reasons: (1) the path length difference occurs in a medium other than air, and (2) reflections are involved, which can change the phase.

The phase difference between two waves can change if one or both are reflected.

Let’s next discuss changes in phase that are caused by reflections.
Reflection Phase Shifts

Refraction at an interface never causes a phase change—but reflection can, depending on the indexes of refraction on the two sides of the interface. Figure 35-16 shows what happens when reflection causes a phase change, using as an example pulses on a denser string (along which pulse travel is relatively slow) and a lighter string (along which pulse travel is relatively fast).

When a pulse traveling relatively slowly along the denser string in Fig. 35-16a reaches the interface with the lighter string, the pulse is partially transmitted and partially reflected, with no change in orientation. For light, this situation corresponds to the incident wave traveling in the medium of greater index of refraction \( n \) (recall that greater \( n \) means slower speed). In that case, the wave that is reflected at the interface does not undergo a change in phase; that is, its reflection phase shift is zero.

When a pulse traveling more quickly along the lighter string in Fig. 35-16b reaches the interface with the denser string, the pulse is again partially transmitted and partially reflected. The transmitted pulse again has the same orientation as the incident pulse, but now the reflected pulse is inverted. For a sinusoidal wave, such an inversion involves a phase change of \( \pi \) rad, or half a wavelength. For light, this situation corresponds to the incident wave traveling in the medium of lesser index of refraction (with greater speed). In that case, the wave that is reflected at the interface undergoes a phase shift of \( \pi \) rad, or half a wavelength.

We can summarize these results for light in terms of the index of refraction of the medium off which (or from which) the light reflects:

<table>
<thead>
<tr>
<th>Reflection</th>
<th>Reflection phase shift</th>
</tr>
</thead>
<tbody>
<tr>
<td>Off lower index</td>
<td>0</td>
</tr>
<tr>
<td>Off higher index</td>
<td>0.5 wavelength</td>
</tr>
</tbody>
</table>

This might be remembered as “higher means half.”

Equations for Thin-Film Interference

In this chapter we have now seen three ways in which the phase difference between two waves can change:

1. by reflection
2. by the waves traveling along paths of different lengths
3. by the waves traveling through media of different indexes of refraction

When light reflects from a thin film, producing the waves of rays \( r_1 \) and \( r_2 \) shown in Fig. 35-15, all three ways are involved. Let us consider them one by one.

Reflection Shift. We first reexamine the two reflections in Fig. 35-15. At point \( a \) on the front interface, the incident wave (in air) reflects from the medium having the higher of the two indexes of refraction; so the wave of reflected ray \( r_1 \) has its phase shifted by 0.5 wavelength. At point \( b \) on the back interface, the incident wave reflects from the medium (air) having the lower of the two indexes of refraction; so the wave reflected there is not shifted in phase by the reflection, and thus neither is the portion of it that exits the film as ray \( r_2 \). We can organize this information with the first line in Table 35-1, which refers to the simplified drawing in Fig. 35-17 for a thin film in air. So far, as a result of the reflection phase shifts, the waves of \( r_1 \) and \( r_2 \) have a phase difference of 0.5 wavelength and thus are exactly out of phase.

Path Length Difference. Now we must consider the path length difference \( 2L \) that occurs because the wave of ray \( r_2 \) crosses the film twice. (This difference
2L is shown on the second line in Table 35-1.) If the waves of \( r_1 \) and \( r_2 \) are to be exactly in phase so that they produce fully constructive interference, the path length \( 2L \) must cause an additional phase difference of 0.5, 1.5, 2.5, \ldots wavelengths. Only then will the net phase difference be an integer number of wavelengths. Thus, for a bright film, we must have

\[ 2L = \frac{\text{odd number}}{2} \times \text{wavelength} \quad \text{(in-phase waves)}. \tag{35-31} \]

The wavelength we need here is the wavelength \( \lambda_{n_2} \) of the light in the medium containing path length \( 2L \)—that is, in the medium with index of refraction \( n_2 \). Thus, we can rewrite Eq. 35-31 as

\[ 2L = \frac{\text{odd number}}{2} \times \lambda_{n_2} \quad \text{(in-phase waves)}. \tag{35-32} \]

If, instead, the waves are to be exactly out of phase so that there is fully destructive interference, the path length \( 2L \) must cause either no additional phase difference or a phase difference of 1, 2, 3, \ldots wavelengths. Only then will the net phase difference be an odd number of half-wavelengths. For a dark film, we must have

\[ 2L = \text{integer} \times \lambda_{n_2} \quad \text{(out-of-phase waves)}. \tag{35-33} \]

where, again, the wavelength is the wavelength \( \lambda_{n_2} \) in the medium containing \( 2L \). Thus, this time we have

\[ 2L = \text{integer} \times \lambda_{n_2} \quad \text{(out-of-phase waves)}. \tag{35-34} \]

Now we can use Eq. 35-6 (\( \lambda_n = \lambda/n \)) to write the wavelength of the wave of ray \( r_2 \) inside the film as

\[ \lambda_{n_2} = \frac{\lambda}{n_2}, \tag{35-35} \]

where \( \lambda \) is the wavelength of the incident light in vacuum (and approximately also in air). Substituting Eq. 35-35 into Eq. 35-32 and replacing “odd number/2” with \( (m + \frac{1}{2}) \) give us

\[ 2L = (m + \frac{1}{2}) \frac{\lambda}{n_2}, \quad \text{for } m = 0, 1, 2, \ldots \quad \text{(maxima—bright film in air).} \tag{35-36} \]

Similarly, with \( m \) replacing “integer,” Eq. 35-34 yields

\[ 2L = m \frac{\lambda}{n_2}, \quad \text{for } m = 0, 1, 2, \ldots \quad \text{(minima—dark film in air).} \tag{35-37} \]

For a given film thickness \( L \), Eqs. 35-36 and 35-37 tell us the wavelengths of light for which the film appears bright and dark, respectively, one wavelength for each value of \( m \). Intermediate wavelengths give intermediate brightnesses. For a given wavelength \( \lambda \), Eqs. 35-36 and 35-37 tell us the thicknesses of the films that appear bright and dark in that light, respectively, one thickness for each value of \( m \). Intermediate thicknesses give intermediate brightnesses.

**Heads Up.** (1) For a thin film surrounded by air, Eq. 35-36 corresponds to bright reflections and Eq. 35-37 corresponds to no reflections. For transmissions, the roles of the equations are reversed (after all, if the light is brightly reflected, then it is not transmitted, and vice versa). (2) If we have a different set of values of the indexes of refraction, the roles of the equations may be reversed. For any given set of indexes, you must go through the thought process behind Table 35-1 and, in particular, determine the reflection shifts to see which equation applies to bright reflections and which applies to no reflections. (3) The index of refraction in the equations is that of the thin film, where the path length difference occurs.

Film Thickness Much Less Than $\lambda$

A special situation arises when a film is so thin that $L$ is much less than $\lambda$, say, $L < 0.1 \lambda$. Then the path length difference $2L$ can be neglected, and the phase difference between $r_1$ and $r_2$ is due only to reflection phase shifts. If the film of Fig. 35-17, where the reflections cause a phase difference of 0.5 wavelength, has thickness $L < 0.1 \lambda$, then $r_1$ and $r_2$ are exactly out of phase, and thus the film is dark, regardless of the wavelength and intensity of the light. This special situation corresponds to $m = 0$ in Eq. 35-37. We shall count any thickness $L < 0.1 \lambda$ as being the least thickness specified by Eq. 35-37 to make the film of Fig. 35-17 dark. (Every such thickness will correspond to $m = 0$.) The next greater thickness that will make the film dark is that corresponding to $m = 1$.

In Fig. 35-18, bright white light illuminates a vertical soap film whose thickness increases from top to bottom. However, the top portion is so thin that it is dark. In the (somewhat thicker) middle we see fringes, or bands, whose color depends primarily on the wavelength at which reflected light undergoes fully constructive interference for a particular thickness. Toward the (thickest) bottom the fringes become progressively narrower and the colors begin to overlap and fade.

Sample Problem 35.05  Thin-film interference of a water film in air

White light, with a uniform intensity across the visible wavelength range of 400 to 690 nm, is perpendicularly incident on a water film, of index of refraction $n_2 = 1.33$ and thickness $L = 320 \text{ nm}$, that is suspended in air. At what wavelength $\lambda$ is the light reflected by the film brightest to an observer?

**KEY IDEA**

The reflected light from the film is brightest at the wavelengths $\lambda$ for which the reflected rays are in phase with one another. The equation relating these wavelengths $\lambda$ to the given film thickness $L$ and film index of refraction $n_2$ is either Eq. 35-36 or Eq. 35-37, depending on the reflection phase shifts for this particular film.

**Calculations:** To determine which equation is needed, we should fill out an organizing table like Table 35-1. However, because there is air on both sides of the water film, the situation here is exactly like that in Fig. 35-17, and thus the table would be exactly like Table 35-1. Then from Table 35-1, we see that the reflected rays are in phase (and thus the film is brightest) when

$$2L = \text{odd number} \times \frac{\lambda}{n_2},$$

which leads to Eq. 35-36:

$$2L = (m + \frac{1}{2}) \frac{\lambda}{n_2}.$$

Solving for $\lambda$ and substituting for $L$ and $n_2$, we find

$$\lambda = \frac{2n_2L}{m + \frac{1}{2}} = \frac{(2)(1.33)(320 \text{ nm})}{m + \frac{1}{2}} = \frac{851 \text{ nm}}{m + \frac{1}{2}}.$$

For $m = 0$, this gives us $\lambda = 1700 \text{ nm}$, which is in the infrared region. For $m = 1$, we find $\lambda = 567 \text{ nm}$, which is yellow-green light, near the middle of the visible spectrum. For $m = 2$, $\lambda = 340 \text{ nm}$, which is in the ultraviolet region. Thus, the wavelength at which the light seen by the observer is brightest is $\lambda = 567 \text{ nm}$.  

(Answer)
Sample Problem 35.06 Thin-film interference of a coating on a glass lens

In Fig. 35-19, a glass lens is coated on one side with a thin film of magnesium fluoride (MgF₂) to reduce reflection from the lens surface. The index of refraction of MgF₂ is 1.38; that of the glass is 1.50. What is the least coating thickness that eliminates (via interference) the reflections at the middle of the visible spectrum (λ = 550 nm)? Assume that the light is approximately perpendicular to the lens surface.

KEY IDEA

Reflection is eliminated if the film thickness $L$ is such that light waves reflected from the two film interfaces are exactly out of phase. The equation relating $L$ to the given wavelength $\lambda$ and the index of refraction $n_2$ of the thin film is either Eq. 35-36 or Eq. 35-37, depending on the reflection phase shifts at the interfaces.

Calculations: To determine which equation is needed, we fill out an organizing table like Table 35-1. At the first interface, the incident light is in air, which has a lesser index of refraction than the MgF₂ (the thin film). Thus, we fill in 0.5 wavelength under $r_1$ in our organizing table (meaning that the waves of ray $r_1$ are shifted by 0.5λ at the first interface). At the second interface, the incident light is in the MgF₂, which has a lesser index of refraction than the glass on the other side of the interface. Thus, we fill in 0.5 wavelength under $r_2$ in our table.

Because both reflections cause the same phase shift, they tend to put the waves of $r_1$ and $r_2$ out of phase. Since we want those waves to be out of phase, their path length difference $2L$ must be an odd number of half-wavelengths:

$$2L = \frac{\text{odd number}}{2} \times \frac{\lambda}{n_2}.$$  

This leads to Eq. 35-36 (for a bright film sandwiched in air but for a dark film in the arrangement here). Solving that equation for $L$ then gives us the film thicknesses that will eliminate reflection from the lens and coating:

$$L = \left( m + \frac{1}{2} \right) \frac{\lambda}{2n_2} \quad \text{for } m = 0, 1, 2, \ldots \quad (35-38)$$

We want the least thickness for the coating—that is, the smallest value of $L$. Thus, we choose $m = 0$, the smallest possible value of $m$. Substituting it and the given data in Eq. 35-38, we obtain

$$L = \frac{\lambda}{4n_2} = \frac{550 \text{ nm}}{(4)(1.38)} = 99.6 \text{ nm}. \quad (\text{Answer})$$

Sample Problem 35.07 Thin-film interference of a transparent wedge

Figure 35-20a shows a transparent plastic block with a thin wedge of air at the right. (The wedge thickness is exaggerated in the figure.) A broad beam of red light, with wavelength $\lambda = 632.8 \text{ nm}$, is directed downward through the top of the block (at an incidence angle of $\theta^\circ$). Some of the light that passes into the plastic is reflected back up from the top and bottom surfaces of the wedge, which acts as a thin film (of air) with a thickness that varies uniformly and gradually from $L_L$ at the left-hand end to $L_R$ at the right-hand end. (The plastic layers above and below the wedge of air are too thick to act as thin films.) An observer looking down on the block sees an interference pattern consisting of six dark fringes and five bright red fringes along the wedge. What is the change in thickness $\Delta L \ (= L_R - L_L)$ along the wedge?

KEY IDEAS

(1) The brightness at any point along the left–right length of the air wedge is due to the interference of the waves reflected at the top and bottom interfaces of the wedge. (2) The variation of brightness in the pattern of bright and dark fringes is due to the variation in the thickness of the wedge. In some regions, the thickness puts the reflected waves in phase and thus produces a bright reflection (a bright red fringe). In other regions, the thickness puts the reflected waves out of phase and thus produces no reflection (a dark fringe).

Organizing the reflections: Because the observer sees more dark fringes than bright fringes, we can assume that a dark fringe is produced at both the left and right ends of
This dark fringe is due to fully destructive interference. So, the reflected rays must be out of phase.

The path length difference (down and back up) is $2L$.

Total reflection shift = 0.5 wavelength. So, the reflections put the waves out of phase.

We want the reflected waves to be out of phase. They already are out of phase because of the reflection shifts. So, we don’t want the path length difference $2L$ to change that. Thus, $2L = (\text{integer})\lambda/n_2$.

**Figure 35-20** (a) Red light is incident on a thin, air-filled wedge in the side of a transparent plastic block. The thickness of the wedge is $L_L$ at the left end and $L_R$ at the right end. (b) The view from above the block: an interference pattern of six dark fringes and five bright red fringes lies over the region of the wedge. (c) A representation of the incident ray $i$, reflected rays $r_1$ and $r_2$, and thickness $L$ of the wedge anywhere along the length of the wedge. The reflection rays at the (d) left and (f) right ends of the wedge and (e) their organizing table.
the wedge. Thus, the interference pattern is that shown in Fig. 35-20b.

We can represent the reflection of light at the top and bottom interfaces of the wedge, at any point along its length, with Fig. 35-20c, in which \( L \) is the wedge thickness at that point. Let us apply this figure to the left end of the wedge, where the reflections give a dark fringe.

We know that, for a dark fringe, the waves of rays \( r_1 \) and \( r_2 \) in Fig. 35-20d must be out of phase. We also know that the equation relating the film thickness \( L \) to the light’s wavelength \( \lambda \) and the film’s index of refraction \( n_2 \) is either Eq. 35-36 or Eq. 35-37, depending on the reflection phase shifts. To determine which equation gives a dark fringe at the left end of the wedge, we should fill out an organizing table like Table 35-1, as shown in Fig. 35-20e.

At the top interface of the wedge, the incident light is in the plastic, which has a greater \( n \) than the air beneath that interface. So, we fill in 0 under \( r_1 \) in our organizing table. At the bottom interface of the wedge, the incident light is in air, which has a lesser \( n \) than the plastic beneath that interface. So we fill in 0.5 wavelength under \( r_2 \). So, the phase difference due to the reflection shifts is 0.5 wavelength. Thus the reflections alone tend to put the waves of \( r_1 \) and \( r_2 \) out of phase.

**Reflections at left end (Fig. 35-20d):** Because we see a dark fringe at the left end of the wedge, which the reflection phase shifts alone would produce, we don’t want the path length difference to alter that condition. So, the path length difference \( 2L \) at the left end must be given by

\[
2L = \text{integer} \times \frac{\lambda}{n_2},
\]

which leads to Eq. 35-37:

\[
2L = m \frac{\lambda}{n_2}, \quad \text{for } m = 0, 1, 2, \ldots \quad (35-39)
\]

**Reflections at right end (Fig. 35-20f):** Equation 35-39 holds not only for the left end of the wedge but also for any point along the wedge where a dark fringe is observed, including the right end, with a different integer value of \( m \) for each fringe. The least value of \( m \) is associated with the least thickness of the wedge where a dark fringe is observed. Progressively greater values of \( m \) are associated with progressively greater thicknesses of the wedge where a dark fringe is observed. Let \( m_L \) be the value at the left end. Then the value at the right end must be \( m_L + 5 \) because, from Fig. 35-20b, the right end is located at the fifth dark fringe from the left end.

**Thickness difference:** To find \( \Delta L \), we first solve Eq. 35-39 twice—one for the thickness \( L_L \) at the left end and once for the thickness \( L_R \) at the right end:

\[
L_L = (m_L) \frac{\lambda}{2n_2}, \quad L_R = (m_L + 5) \frac{\lambda}{2n_2}. \quad (35-40)
\]

We can now subtract \( L_L \) from \( L_R \) and substitute \( n_2 = 1.00 \) for the air within the wedge and \( \lambda = 632.8 \times 10^{-8} \) m:

\[
\Delta L = L_R - L_L = (m_L + 5)\frac{\lambda}{2n_2} - m_L \frac{\lambda}{2n_2} = \frac{5}{2} \frac{\lambda}{n_2}
\]

\[
= 1.58 \times 10^{-6} \text{ m.} \quad \text{(Answer)}
\]

---

### 35-5 MICHELSON’S INTERFEROMETER

**Learning Objectives**

*After reading this module, you should be able to . . .*

- **35.35** With a sketch, explain how an interferometer works.
- **35.36** When a transparent material is inserted into one of the beams in an interferometer, apply the relationship between the phase change of the light (in terms of wavelength) and the material’s thickness and index of refraction.
- **35.37** For an interferometer, apply the relationship between the distance a mirror is moved and the resulting fringe shift in the interference pattern.

**Key Ideas**

- In Michelson’s interferometer, a light wave is split into two beams that then recombine after traveling along different paths.
- The interference pattern they produce depends on the difference in the lengths of those paths and the indexes of refraction along the paths.
- If a transparent material of index \( n \) and thickness \( L \) is in one path, the phase difference (in terms of wavelength) in the recombining beams is equal to
  \[
  \text{phase difference} = \frac{2L}{\lambda} (n - 1),
  \]
  where \( \lambda \) is the wavelength of the light.

---

Additional examples, video, and practice available at WileyPLUS
Michelson’s Interferometer

An interferometer is a device that can be used to measure lengths or changes in length with great accuracy by means of interference fringes. We describe the form originally devised and built by A. A. Michelson in 1881.

Consider light that leaves point \( P \) on extended source \( S \) in Fig. 35-21 and encounters beam splitter \( M \). A beam splitter is a mirror that transmits half the incident light and reflects the other half. In the figure we have assumed, for convenience, that this mirror possesses negligible thickness. At \( M \) the light thus divides into two waves. One proceeds by transmission toward mirror \( M_1 \) at the end of one arm of the instrument; the other proceeds by reflection toward mirror \( M_2 \) at the end of the other arm. The waves are entirely reflected at these mirrors and are sent back along their directions of incidence, each wave eventually entering telescope \( T \). What the observer sees is a pattern of curved or approximately straight interference fringes; in the latter case the fringes resemble the stripes on a zebra.

Mirror Shift. The path length difference for the two waves when they recombine at the telescope is \( 2d_2 - 2d_1 \), and anything that changes this path length difference will cause a change in the phase difference between these two waves at the eye. As an example, if mirror \( M_2 \) is moved by a distance \( \frac{1}{2} \lambda \), the path length difference is changed by \( \lambda \) and the fringe pattern is shifted by one fringe (as if each dark stripe on a zebra had moved to where the adjacent dark stripe had been). Similarly, moving mirror \( M_1 \) by \( \frac{1}{2} \lambda \) causes a shift by half a fringe (each dark zebra stripe shifts to where the adjacent white stripe had been).

Insertion. A shift in the fringe pattern can also be caused by the insertion of a thin transparent material into the optical path of one of the mirrors—say, \( M_1 \). If the material has thickness \( L \) and index of refraction \( n \), then the number of wavelengths along the light’s to-and-fro path through the material is, from Eq. 35-7,

\[
N_m = \frac{2L}{\lambda} = \frac{2Ln}{\lambda}.
\]  

(35-41)

The number of wavelengths in the same thickness \( 2L \) of air before the insertion of the material is

\[
N_a = \frac{2L}{\lambda}.
\]  

(35-42)

When the material is inserted, the light returned from mirror \( M_1 \) undergoes a phase change (in terms of wavelengths) of

\[
N_m - N_a = \frac{2Ln}{\lambda} - \frac{2L}{\lambda} = \frac{2L}{\lambda} (n - 1).
\]  

(35-43)

For each phase change of one wavelength, the fringe pattern is shifted by one fringe. Thus, by counting the number of fringes through which the material causes the pattern to shift, and substituting that number for \( N_m - N_a \) in Eq. 35-43, you can determine the thickness \( L \) of the material in terms of \( \lambda \).

Standard of Length. By such techniques the lengths of objects can be expressed in terms of the wavelengths of light. In Michelson’s day, the standard of length—the meter—was the distance between two fine scratches on a certain metal bar preserved at Sèvres, near Paris. Michelson showed, using his interferometer, that the standard meter was equivalent to \( \lambda = 553 163.5 \) wavelengths of a certain monochromatic red light emitted from a light source containing cadmium. For this careful measurement, Michelson received the 1907 Nobel Prize in physics. His work laid the foundation for the eventual abandonment (in 1961) of the meter bar as a standard of length and for the redefinition of the meter in terms of the wavelength of light. By 1983, even this wavelength standard was not precise enough to meet the growing technical needs, and it was replaced with a new standard based on a defined value for the speed of light.
Huygens’ Principle  The three-dimensional transmission of waves, including light, may often be predicted by Huygens’ principle, which states that all points on a wavefront serve as point sources of spherical secondary wavelets. After a time $t$, the new position of the wavefront will be that of a surface tangent to these secondary wavelets.

The law of refraction can be derived from Huygens’ principle by assuming that the index of refraction of any medium is $n = c/v$, in which $v$ is the speed of light in the medium and $c$ is the speed of light in vacuum.

Wavelength and Index of Refraction  The wavelength $\lambda_n$ of light in a medium depends on the index of refraction $n$ of the medium:

$$\lambda_n = \frac{\lambda}{n}$$  

(35-6)

in which $\lambda$ is the wavelength in vacuum. Because of this dependency, the phase difference between two waves can change if they pass through different materials with different indexes of refraction.

Young’s Experiment  In Young’s interference experiment, light passing through a single slit falls on two slits in a screen. The light leaving these slits flares out (by diffraction), and interference occurs in the region beyond the screen. A fringe pattern, due to the interference, forms on a viewing screen.

The light intensity at any point on the viewing screen depends in part on the difference in the path lengths from the slits to that point. If this difference is an integer number of wavelengths, the waves interfere constructively and an intensity maximum results. If it is an odd number of half-wavelengths, there is destructive interference and an intensity minimum occurs. The conditions for maximum and minimum intensity are

$$d \sin \theta = m\lambda, \quad \text{for } m = 0, 1, 2, \ldots$$  

(maxima — bright fringes),  

(35-14)

$$d \sin \theta = (m + \frac{1}{2})\lambda, \quad \text{for } m = 0, 1, 2, \ldots$$  

(minima — dark fringes),  

(35-16)

where $\theta$ is the angle the light path makes with a central axis and $d$ is the slit separation.

Coherence  If two light waves that meet at a point are to interfere perceptibly, the phase difference between them must remain constant with time; that is, the waves must be coherent. When two coherent waves meet, the resulting intensity may be found by using phasors.

Intensity in Two-Slit Interference  In Young’s interference experiment, two waves, each with intensity $I_0$, yield a resultant wave of intensity $I$ at the viewing screen, with

$$I = 4I_0 \cos^2 \frac{1}{2} \phi, \quad \text{where } \phi = \frac{2\pi d}{\lambda} \sin \theta.$$  

(35-22, 35-23)

Equations 35-14 and 35-16, which identify the positions of the fringe maxima and minima, are contained within this relation.

Thin-Film Interference  When light is incident on a thin transparent film, the light waves reflected from the front and back surfaces interfere. For near-normal incidence, the wavelength conditions for maximum and minimum intensity of the light reflected from a film in air are

$$2L = (m + \frac{1}{2}) \frac{\lambda}{n_f}, \quad \text{for } m = 0, 1, 2, \ldots$$  

(maxima — bright film in air),  

(35-36)

$$2L = m \frac{\lambda}{n_f}, \quad \text{for } m = 0, 1, 2, \ldots$$  

(minima — dark film in air),  

(35-37)

where $n_f$ is the index of refraction of the film, $L$ is its thickness, and $\lambda$ is the wavelength of the light in air.

If the light incident at an interface between media with different indexes of refraction is in the medium with the smaller index of refraction, the reflection causes a phase change of $\pi$ rad, or half a wavelength, in the reflected wave. Otherwise, there is no phase change due to the reflection. Refraction causes no phase shift.

The Michelson Interferometer  In Michelson’s interferometer a light wave is split into two beams that, after traversing paths of different lengths, are recombined so they interfere and form a fringe pattern. Varying the path length of one of the beams allows distances to be accurately expressed in terms of wavelengths of light, by counting the number of fringes through which the pattern shifts because of the change.

Questions

1. Does the spacing between fringes in a two-slit interference pattern increase, decrease, or stay the same if (a) the slit separation is increased, (b) the color of the light is switched from red to blue, and (c) the whole apparatus is submerged in cooking sherry? (d) If the slits are illuminated with white light, then at any side maximum, does the blue component or the red component peak closer to the central maximum?

2. (a) If you move from one bright fringe in a two-slit interference pattern to the next one farther out, (b) does the path length difference $\Delta L$ increase or decrease and (c) by how much does it change, in wavelengths $\lambda$?

3. Figure 35-22 shows two light rays that are initially exactly in phase and that reflect from several glass surfaces. Neglect the slight slant in the path of the light in the second arrangement. (a) What is the path length difference of the rays? In wavelengths $\lambda$ (b) what should that path length difference equal if the rays are to be exactly out of phase when they emerge, and (c) what is the smallest value of $d$ that will allow that final phase difference?

4. In Fig. 35-23, three pulses of light—$a$, $b$, and $c$—of the same wavelength are sent through layers
of plastic having the given indexes of refraction and along the
paths indicated. Rank the pulses according to their travel time
through the plastic layers, greatest first.

5 Is there an interference maximum, a minimum, an intermediate
state closer to a maximum, or an intermediate state closer to a
minimum at point $P$ in Fig. 35-10 if the path length difference of
the two rays is (a) 2.2$\lambda$, (b) 3.5$\lambda$, (c) 1.8$\lambda$, and (d) 1.0$\lambda$? For each
situation, give the value of $m$ associated with the maximum or
minimum involved.

6 Figure 35-24a gives intensity $I$ versus position $x$ on the viewing
screen for the central portion of a two-slit interference pattern.
The other parts of the figure give phasor diagrams for the electric
field components of the waves arriving at the screen from the two
slits (as in Fig. 35-13a). Which numbered points on the screen best
 correspond to which phasor diagram?

![Figure 35-24 Question 6.]

7 Figure 35-25 shows two sources $S_1$ and $S_2$ that emit radio waves
of wavelength $\lambda$ in all directions. The sources are exactly in phase
and are separated by a distance equal to 1.5$\lambda$. The vertical broken
line is the perpendicular bisector of the distance between the
sources. (a) If we start at the indicated start point and travel along
path 1, does the interference produce a maximum all along the
path, a minimum all along the path, or alternating maxima and
minima? Repeat for (b) path 2 (along an axis through the sources)
and (c) path 3 (along a perpendicular to that axis).

![Figure 35-25 Question 7.]

8 Figure 35-26 shows two rays of light, of wavelength 600 nm, that reflect
from glass surfaces separated by 150 nm. The rays are initially in
phase. (a) What is the path length difference of the rays? (b) When
they have cleared the reflection region, are the rays exactly in phase,
exactly out of phase, or in some intermediate state?

9 Light travels along the length of a 1500-nm-long nanostructure.
When a peak of the wave is at one end of the nanostructure, is there a peak or a valley at the other end if the wavelength is (a) 500
nm and (b) 1000 nm?

10 Figure 35-27a shows the cross section of a vertical thin film whose
width increases downward because gravitation causes slumping. Figure
35-27b is a face-on view of the film, showing four bright (red) interference fringes that result when the film is illuminated with a perpendicular
beam of red light. Points in the cross section corresponding to the bright fringes are labeled. In terms of the wavelength of the light inside the film, what is the
difference in film thickness between (a) points $a$ and $b$ and (b)
points $b$ and $d$?

11 Figure 35-28 shows four situations in which light reflects perpendicularly from a thin film of thickness $L$ sandwiched between much thicker materials. The indexes of refraction are given. In
which situations does Eq. 35-36 correspond to the reflections yielding
maxima (that is, a bright film)?

![Figure 35-28 Question 11.]

12 Figure 35-29 shows the transmission of light through a thin film
in air by a perpendicular beam (tilted in the figure for clarity). (a) Did
ray $r_3$ undergo a phase shift due to reflection? (b) In wavelengths,
what is the reflection phase shift for ray $r_3$? (c) If the film thickness is $L$, what is the path length difference between rays $r_3$ and $r_4$?

![Figure 35-29 Question 12.]

13 Figure 35-30 shows three situations in which two rays of sunlight
penetrate slightly into and then scatter out of lunar soil. Assume that
the rays are initially in phase. In which situation are the associated waves most likely to end up in phase? Just as the Moon becomes full, its brightness suddenly peaks, becoming 25%
greater than its brightness on the nights before and after, because
at full Moon we intercept light waves that are scattered by lunar
soil back toward the Sun and undergo constructive interference at
our eyes. Before astronauts first landed on the Moon, NASA was
concerned that backscatter of sunlight from the soil might blind
the lunar astronauts if they did not have proper viewing shields on
their helmets.

![Figure 35-30 Question 13.]
Module 35-1 Light as a Wave

1 In Fig. 35-31, a light wave along ray $r_1$ reflects once from a mirror and a light wave along ray $r_2$ reflects twice from that same mirror and once from a tiny mirror at distance $L$ from the bigger mirror. (Neglect the slight tilt of the rays.) The waves have wavelength 620 nm and are initially in phase. (a) What is the smallest value of $L$ that puts the final light waves exactly out of phase? (b) With the tiny mirror initially at that value of $L$, how far must it be moved away from the bigger mirror to again put the final waves out of phase?

2 In Fig. 35-31, a light wave along ray $r_1$ reflects once from a mirror and a light wave along ray $r_2$ reflects twice from that same mirror and once from a tiny mirror at distance $L$ from the bigger mirror. (Neglect the slight tilt of the rays.) The waves have wavelength $\lambda$ and are initially exactly out of phase. What are the (a) smallest, (b) second smallest, and (c) third smallest values of $L/\lambda$ that result in the final waves being exactly in phase?

3 SSM In Fig. 35-4, assume that two waves of light in air, of wavelength 400 nm, are initially in phase. One travels through a glass layer of index of refraction $n_1 = 1.60$ and thickness $L$. The other travels through an equally thick plastic layer of index of refraction $n_2 = 1.50$. (a) What is the smallest value of $L$ should have if the waves are to end up with a phase difference of 5.65 rad? (b) If the waves arrive at some common point with the same amplitude, is their interference fully constructive, fully destructive, intermediate but closer to fully constructive, or intermediate but closer to fully destructive?

4 In Fig. 35-32a, a beam of light in material 1 is incident on a boundary at an angle of $30^\circ$. The extent to which the light is bent due to refraction depends, in part, on the index of refraction $n_2$ of material 2. Figure 35-32b gives the angle of refraction $\theta_2$ versus $n_2$ for a range of possible $n_2$ values, from $n_a = 1.30$ to $n_b = 1.90$. What is the speed of light in material 1?

5 How much faster, in meters per second, does light travel in sapphire than in diamond? See Table 33-1.

6 The wavelength of yellow sodium light in air is 589 nm. (a) What is its frequency? (b) What is its wavelength in glass whose index of refraction is 1.52? (c) From the results of (a) and (b), find its speed in this glass.

7 The speed of yellow light (from a sodium lamp) in a certain liquid is measured to be $1.92 \times 10^8$ m/s. What is the index of refraction of this liquid for the light?

8 In Fig. 35-33, two light pulses are sent through layers of plastic with thicknesses of either $L$ or $2L$ as shown and indexes of refraction $n_1 = 1.55, n_2 = 1.70, n_3 = 1.60, n_4 = 1.45, n_5 = 1.59, n_6 = 1.65$, and $n_7 = 1.50$. (a) Which pulse travels through the plastic in less time? (b) What multiple of $L/c$ gives the difference in the traversal times of the pulses?

9 In Fig. 35-4, assume that the two light waves, of wavelength 620 nm in air, are initially out of phase by $\pi$ rad. The indexes of refraction of the media are $n_1 = 1.45$ and $n_2 = 1.65$. What are the (a) smallest and (b) second smallest value of $L$ that will put the waves exactly in phase once they pass through the two media?

10 In Fig. 35-34, a light ray is incident at angle $\theta_1 = 50^\circ$ on a series of five transparent layers with parallel boundaries. For layers 1 and 3, $L_1 = 20 \mu m, L_3 = 25 \mu m, n_1 = 1.6, \text{ and } n_3 = 1.45$. (a) At what angle does the light emerge back into air at the right? (b) How much time does the light take to travel through layer 3?

11 Suppose that the two waves in Fig. 35-4 have wavelength $\lambda = 500$ nm in air. What multiple of $\lambda$ gives their phase difference when they emerge if (a) $n_1 = 1.50, n_2 = 1.60$, and $L = 8.50 \mu m$; (b) $n_1 = 1.62, n_2 = 1.72, \text{ and } L = 8.50 \mu m$; and (c) $n_1 = 1.59, n_2 = 1.79, \text{ and } L = 3.25 \mu m$? (d) Suppose that in each of these three situations the waves arrive at a common point (with the same amplitude) after emerging. Rank the situations according to the brightness the waves produce at the common point.

12 In Fig. 35-35, two light rays go through different paths by reflecting from the various flat surfaces shown. The light waves have a wavelength of 420.0 nm and are initially in phase. What are the (a) smallest and (b) second smallest value of distance $L$ that will put the waves exactly out of phase as they emerge from the region?

13 SSM ILW Two waves of light in air, of wavelength $\lambda = 600.0$ nm, are initially in phase. They then
both travel through a layer of plastic as shown in Fig. 35-36, with $L_1 = 4.00 \mu m$, $L_2 = 3.50 \mu m$, $n_1 = 1.40$, and $n_2 = 1.60$.
